EVIDENCE	1—396
LIST OF APPENDICES	397
APPENDICES	399—661

LIST OF WITNESSES.

FORTY-FIFTH DAY: 11TH FEBRUARY 1899: BOMBAY.

Mr. R. B. Stewart, I.C.S.	1—4
Lieutenant-Colonel G. Waters, I.M.S.	4—9
Major B. B. Grayfoot, I.M.S.	9—14
Mr. F. M. Gibson (further examined)	14—16
Dr. C. Balfour Stewart	16—17

FORTY-SIXTH DAY: 13TH FEBRUARY 1899: BOMBAY.

Assistant-Surgeon P. V. Shikare	17—18
Dr. A. Mayr	18—21
Captain C. J. R. Milne, I.M.S.	21—25
Lieutenant J. K. Condon, I.S.C.	25—26
Mr. S. R. Arthur, I.C.S.	26—28
Dr. T. Blaney	28—32

FORTY-SEVENTH DAY: 14TH FEBRUARY 1899: BOMBAY.

Mr. Ismail Jan Mahomad	33—37
Mr. George Lund	37—39
Mr. N. N. Katrak	39—40
Mr. J. McDonald	40—42
Mr. A. B. Davur	42—45
Mr. L. Godinho	45—47
Mr. A. H. Simcox, I.C.S.	47—48

FORTY-EIGHTH DAY: 15TH FEBRUARY 1899: BOMBAY.

Lieutenant-Colonel W. G. H. Henderson, I.M.S.	48—50
Mr. K. B. Shroff	50—52
Mr. K. A. Dodihalkar	52—53
Mr. K. S. Engineer	53—55
Major Richard Baker, I.M.S.	55—57
Mr. G. W. Roughton	57—59
Mr. A. Britto	59—60

FORTY-NINTH DAY: 17TH FEBRUARY 1899: BOMBAY. — Pages

Mr. Reginald Gilbert ... 61—63
Professor T. K. Gajjar ... 63—67
Mr. W. C. Shepherd, I.C.S. ... 67—68
Mr. Ernest L. Marsh ... 68—74
Mr. E. F. Allum ... 74—75
Mr. R. J. C. Lord, I.C.S. ... 75—76
The Hon. Mr. Bhalchandra Krishna ... 77—79
Dr. D. A. D'Monte ... 79—80

FIFTIETH DAY: 18TH FEBRUARY 1899: BOMBAY.

Mr. C. H. Freeman Underwood ... 81—87
Mr. N. Futehally ... 87
Professor O. V. Muller ... 88—89
Mr. J. K. N. Kabraji, I.C.S. ... 89—91

FIFTY-FIRST DAY: 20TH FEBRUARY 1899: BOMBAY.

Mr. Baramjee Naorosji Darabsett ... 92
Mr. Champaklal Thakurdas ... 92—93
Mr. Narayan Muljee ... 93—94
Mr. G. Monteath, I.C.S. ... 94—95
Lieutenant-Colonel A. W. F. Street, I.M.S. ... 95—97
Lieutenant H. P. Keelan, I.S.C. ... 97—100
Dr. W. Venis ... 100—101
Major T. E. Dyson, I.M.S. ... 101—102

FIFTY-SECOND DAY: 21ST FEBRUARY 1899: BOMBAY.

Major M. A. T. Collie, I.M.S. ... 103—106
Captain C. H. L. Meyer, I.M.S. ... 106—108
Mr. W. T. Morison, I.C.S. ... 108—111
Mr. N. A. F. Moos ... 111—113
Mr. A. G. Mackenzie ... 113—114
Mr. C. N. Hall ... 114
Assistant-Surgeon A. King ... 114—115
Major H. P. Dimmock, I.M.S. ... 115—120

FIFTY-THIRD DAY: 22ND FEBRUARY 1899: BOMBAY.

Khan Bahadur N. H. Choksy ... 121—134

FIFTY-FOURTH DAY: 23RD FEBRUARY 1899: POONA.

Captain J. B. Smith, I.M.S. ... 134—139
Lieutenant-Colonel W. J. Fawcett, R.A.M.C. ... 139—145
Mr. H. C. Venis ... 145—150
Professor G. K. Gokhale ... 150—151
Mr. Vishnu Anant Patwardhan ... 151—156
Rai Bahadur B. C. Sathe ... 156—157
Assistant-Surgeon E. S. Bharucha ... 158—159

FIFTY-FIFTH DAY: 24TH FEBRUARY 1899: POONA.

Major W. L. Reade, R.A.M.C. ... 159—168
Captain C. K. Morgan, R.A.M.C. ... 168
Lieutenant-Colonel W. J. Fawcett (further examined) ... 168—169
Dr. W. D. Betenson ... 169—170

FIFTY-SIXTH DAY: 27TH FEBRUARY 1899: SATARA.

	Pages
Mr. C. G. Dodgson, I.C.S.	171—176
Lieutenant-Colonel H. Hay, I.S.C.	176—180
Captain G. S. Thompson, I.M.S.	180—191

FIFTY-SEVENTH DAY: 28TH FEBRUARY 1899: SATARA.

Mr. V. G. Ghanekar	192—193
Lieutenant N. B. Anderson, I.S.C.	193—195
Lieutenant H. C. Steen, I.S.C.	196—199

FIFTY-EIGHTH DAY: 1ST MARCH 1899: BELGAUM.

Mr. G. Carmichael, I.C.S.	200—204
Lieutenant G. B. Kidd, I.S.C.	204—206
Lieutenant-Colonel C. T. Peters, I.M.S.	206—209
Mr. G. Uchgaonkar	209—212

FIFTY-NINTH DAY: 2ND MARCH 1899: BELGAUM.

Major A. V. Anderson, I.M.S.	213—221
Lieutenant G. Thomas, I.S.C.	221—224
Rao Bahadur R. R. Bhardi	224—227
Captain A. F. C. Colomb, I.S.C.	227—231
Mr. J. L. Lushington...	231—232

SIXTIETH DAY: 3RD MARCH 1899: BELGAUM.

Mr. Foy, M.B.	232—235
Major T. H. Hardy, I.S.C. (further examined)	235—236
Major R. H. Forman	236—237
Miss A. M. Corthorn, M.B. (further examined)	237—241

SIXTY-FIRST DAY: 6TH MARCH 1899: SHOLAPUR.

Mr. W. M. Muat, M.B.	241—244
Lieutenant M. E. L. Bruce, I.S.C.	244—246

SIXTY-SECOND DAY: 7TH MARCH 1899: AHMEDNAGAR.

Mr. C. Hudson, I.C.S.	246—247
Captain W. C. Walton, I.S.C.	248—249
Khan Sahib B. S. Cardmaster	250—253
Mr. Mohanlal Hiralal...	253
Mr. Edulji Rustomji	253—254
Major C. F. Willis, I.M.S.	254—255

SIXTY-THIRD DAY: 8TH MARCH 1899: NASIK.

Mr. R. A. L. Moore, I.C.S.	255—258
Lieutenant A. N. Davidson, I.S.C.	259—260
Mr. G. W. Hatch, I.C.S.	260—262

SIXTY-FOURTH DAY: 13TH MARCH 1899: BOMBAY.

Mr. G. Mullanah, M.B. (further examined)	263—270
Captain C. A. Johnston, I.M.S. (further examined)	270—271
Dr. Dinshah Pestanji Ghadiali	271
Mr. P. B. Dantra	271—272

SIXTY-FIFTH DAY: 14TH MARCH 1899: BOMBAY.

	Pages
Colonel D. Robertson, I.S.C. (further examined)	272—273
Mr. P. R. Cadell, I.C.S. (further examined)	274—287
Mr. E. L. Cappel, I.C.S. (further examined)	287—289
Sardar Khan Bahadur Muhammad Yakub Khan	289—290
Khan Bahadur Bomanji Byramji Patel...	290—291
Dr U. L. Desai	291—293

SIXTY-SIXTH DAY: 15TH MARCH 1899: BOMBAY.

Mr. C. H. Cayley, M.B.	293—295
Mr. Sorabji Manekji Damaun-Valla	295—297
Mr. Shrinivasa Rau, M.B. (further examined)	297

SIXTY-SEVENTH DAY: 17TH MARCH 1899: BOMBAY.

Major J. Crimmin, V.C., I.M.S. (further examined)	298—304
Mr. J. H. Du Boulay, I.C.S. (further examined)	305—310
Lieutenant-Colonel T. S. Weir, I.M.S. (further examined)	310—315
Lieutenant H. V. Firth, I.S.C.	315—316

SIXTY-EIGHTH DAY: 20TH MARCH 1899: BOMBAY.

Major W. L. Reade, R.A.M.C. (further examined)	316—320
Mr. S. R. Arthur, I.C.S. (further examined)	320—321
Lieutenant-Colonel E. Lawrie, I.M.S. (further examined)	321—322
Major W. B. Bannerman, I.M.S.	322—323
Dr. D. Galeotti (further examined)	323—327
Mr. C. C. James	327—329

SIXTY-NINTH DAY: 21ST MARCH 1899: BOMBAY.

Captain C. G. Spencer, R.A.M.C.	329—331
Lieutenant S. R. Douglas, I.M.S.	331—337
Lieutenant H. J. Walton, I.M.S.	337—340
Lieutenant W. G. Liston, I.M.S.	340—346

SEVENTIETH DAY: 22ND MARCH 1899: BOMBAY.

Surgeon-General R. Harvey, I.M.S. (further examined)	347—348
Monsieur W. M. Haffkine, C.I.E. (further examined)	348—353
The Hon. Sir Andrew Wingate, I.C.S., K.C.I.E (further examined)	353—358

SEVENTY-FIRST DAY: 6TH MAY 1899: LONDON.

Surgeon-General C. Planck	358—360
Surgeon-Colonel J. Richardson	360—361
Surgeon-General J. Cleghorn, I.M.S.	361—367
Dr. W. J. Simpson	368—379

SEVENTY-SECOND DAY: 20TH MAY 1899: LONDON.

Captain H. D. Mason, R.A.M.C.	380—388
Major R. W. S. Lyons, I.M.S.	389—392
Dr. Klein, F.R.S.	393—396

MINUTES OF EVIDENCE

TAKEN BEFORE THE

INDIAN PLAGUE COMMISSION.

NOTE.—Each witness, as far as was possible, put in a précis of the evidence he was prepared to give. The précis, when available, was printed, and copies of it were distributed to the Members of the Commission prior to each witness' examination. The précis does not form a part of this record of the Commission's Proceedings, but is referred to in the questions put to witnesses in examination.

At The Secretariat, Bombay.

Saturday, 11th February 1899.

FORTY-FIFTH DAY.

PRESENT:

PROF T. R. FRASER, M.D., L.L.D., F.R.S. (*President*).

Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. R. B. STEWART, I.C.S., called and examined.

Mr. R. B. Stewart, I.C.S.

11 Feb. 1899

16,878. (*The President.*) You are Secretary to the Government of Bombay?—I am Acting Secretary.

16,879. You have had experience of plague both in the Nasik district and in Bombay?—Yes.

16,880. In what part of the Nasik district was your first experience?—In Igatpuri.

16,881. At what time did the plague occur there?—We found it first on the 3rd of August 1897. I went down there on that day with Dr. Anderson, who was the Deputy Sanitary Commissioner. We had heard that there were cases there, and we went down to enquire into them. I was Acting Collector and District Magistrate at the time. We found that there were cases, and we reckoned that they must have begun about a fortnight before that—about the middle of July.

16,882. How did you get information?—We heard on the railway line; we were out inspecting a famine camp, and we heard from the railway people that there were cases at Igatpuri.

16,883. Was there no arrangement for obtaining early information of plague cases in this place?—There was a railway surgeon there, but he was not very energetic over it. I think he was rather afraid of going into the houses and examining the patients. The Mamlatdar would have reported the cases had he known of them, but there was no medical man, other than the railway surgeon, to tell him that cases were actually occurring.

16,884. Did you ascertain where the plague had come from?—As far as we could make out it came either from Bombay or Poona. There was plague at both those places at the time. One lot of people had come from Bombay and one lot had come from Poona. We could not make out definitely which had established the plague in Igatpuri; there were cases of plague in both families.

16,885. What action did you take?—A lot of the people had run away.

16,886. Why?—They ran away directly cases occurred.

16,887. They were frightened of the plague?—Yes, they were frightened on account of the plague. Of course at that time of the year it was quite impossible to put anybody out into camp, or huts. The rainfall averaged about 1 inch a day. It was just at the edge of the Ghauts, and the total rainfall during the five months of the monsoon is between 100 and 120 inches, so that we could not do anything in the way of putting people outside. We closed the Municipal school, and took the building for a hospital, and then all we could do was to put the people attacked into hospital, to clear up and disinfect houses which had been vacated by their owners, and put the people from infected houses into them.

16,888. By cleaning up do you mean something different from disinfection?—We had them emptied and washed out and brushed out, and flushed down with perchloride.

16,889. What effect did these measures have on the epidemic; was it checked, or not checked?—I should say it was not checked; it ran its course. The town is really only a long strip alongside the Bombay-Agra road, and there are about two rows of native houses.

16,890. The chief measure you adopted was disinfection?—Yes, and the removal of patients to hospital.

16,891. Notwithstanding that, plague extended?—Yes, it went right through.

16,892. How long did it last?—It lasted for just about 13 weeks.

16,893. Do you know the total number of cases?—No, I could not tell you that.

16,894. What is the total population of Igatpuri?—About 6,000.

16,895. What was the total number of patients?—I cannot give the number of patients in hospital. There were 518 cases of plague and 421 deaths.

Mr. R. B. Stewart, I.C.S.

11 Feb. 1899.

16,896. People ran away. Did they carry the plague elsewhere?—Yes. As far as we could tell, they took it first into Ghoti, which is about four miles off, and is a considerable market town in that part; it is the largest market village about there. They took plague there first. We did not hear about it for some time, and then I heard rumours of cases there, so I sent the Mamlatdar to make inquiries. He went there with an Assistant Surgeon and others and they were assaulted, and several of them badly hurt.

16,897. Do you know why you did not get early information?—Simply from the neglect of the village officials.

16,898. You had an organisation in operation?—We had no organisation, except orders to the officials to keep plague-stricken people out, to be very careful who they let into the village, and to report at once any increase in the number of deaths.

16,899. How large is Ghoti?—The population is about 2,000.

16,900. You had nothing in the nature of house-to-house visitation?—Nothing whatever.

16,901. What action did you take in each case?—Immediately after the riot nearly all the people fled away.

16,902. Where to?—To different villages. Of course there was a police inquiry into the riot. We turned all the rest of the people out, the few who remained—about 200 or so—into huts. Ghoti is a little further away from the edge of the Ghauts than Igatpuri, and the riot took place at the end of September, when the rains were beginning to cease, so we turned them out and disinfected their houses. They got rid of the plague very shortly, but of course the people had nearly all left the village.

16,903. In what time did those that remained become free of plague—the segregated people?—They had a few cases for a week or two only, and then it stopped altogether.

16,904. Another village which was affected was Munmar?—Yes, that was a separate infection. That was not infected from Igatpuri. It is a good deal further up the line; it is a junction between the Dhond and Munmar State Railway and the G. I. P. main line.

16,905. Was your action similar in this case to the last one?—Yes, except that there we got most of the people out of their houses.

16,906. Where did they go to?—They went into their fields; we had better examination there. We had men down there, and they examined the people who remained in the village, and also the people in the fields.

16,907. Those that had removed from their original houses?—Yes, from their houses into their fields; it was dry then.

16,908. Were the houses disinfected?—Yes.

16,909. How long did they remain out of the village?—I could not say definitely how long they remained out. They were not all back when I left Nasik. I left Nasik in February 1898.

16,910. In what month did they go out?—In September and October.

16,911. Had plague ceased when you left?—It had not absolutely ceased.

16,912. That measure, also, was not very effective?—There were very few cases. Of course it is very difficult to control them unless you can keep them all in a camp.

16,913. Were not these people in a camp?—They were not in a camp; they were in the fields.

16,914. When out of control, how do you think the plague continued to extend?—That is very difficult to say. Of course they got back to their houses at night.

16,915. Were not the doors sealed?—No.

16,916. Did they go back, to your knowledge, and sleep in those houses?—They did not go back with our permission.

16,917. Did they sleep in their houses?—Some of them did, undoubtedly.

16,918. You had plague in Nasik itself?—Yes.

16,919. That is a larger town?—It is a town of about 25,000 people.

16,920. Do you know when plague first occurred in Nasik?—The first indigenous cases occurred on the 12th of October 1897.

16,921. Do you know how it was introduced into Nasik?—I believe it was from Ghoti.

16,922. On what grounds do you base that belief?—I did not personally investigate the first one or two cases, so I could not be certain.

16,923. Were you told so, or did you fancy it was so?—I was told by the Civil Surgeon, but I would not be certain whether it was from Bombay or by people coming from Ghoti.

16,924. Did you take measures immediately after the knowledge of the outbreak in Nasik?—We started disinfecting the houses at once.

16,925. What houses?—The houses in which cases occurred.

16,926. How did you effect the disinfection if the people were still in their houses?—The people were taken out.

16,927. The first thing you did was to remove them?—Yes.

16,928. Then you disinfected the houses?—Yes.

16,929. Did you remove any people who lived in the neighbourhood of the infected houses?—Not at the very beginning.

16,930. How long did you wait before you did this?—About a fortnight or three weeks after the first cases. Then we began more wholesale removals.

16,931. In this fortnight in which you were not removing people from neighbouring houses, what was the course of the epidemic: was it checked by the measures then adopted or not?—No.

16,932. Then you adopted more stringent measures?—Then we began moving people out of houses on each side.

16,933. How many houses on each side?—At first we took two on each side; then we found that that was not enough, so we took three on each side, and six opposite. Still it went on, so then we evacuated whole quarters. The town was divided up into wards, and we evacuated gradually the wards as they got infected.

16,934. The wards were completely evacuated?—Yes.

16,935. And a large part of the city was therefore finally evacuated?—The greater part, nearly the whole.

16,936. One side of the river?—One side of the river, yes.

16,937. What was the result of the larger measure—of these final steps?—The plague went on of course. It resulted in, I think, a comparatively small number of cases. There were only about 450 cases in the whole town.

16,938. Before you adopted the final measures how many cases were there?—There were 40 cases up to the second week in November. Then evacuation by wards was commenced.

16,939. After you adopted the final steps how many cases did you have?—It was still going on. We did not evacuate the whole town at any one time.

16,940. The greatest step you took, I understand, was to evacuate all on one side of the river?—It was not all done at once.

16,941. Was the final result that the whole town was evacuated?—All on that side of the river.

16,942. When was that result accomplished?—In the first week in January the last of the blocks on the south of the Godaveri River was evacuated.

16,943. How many cases occurred after the final evacuation?—57 in January and 18 in February. I left Nasik on February 15th.

16,944. Were you fairly well satisfied with the effect of the final action you took?—Yes, I think we would have done better had we evacuated the town more rapidly.

16,945. Could you state generally how it affected the epidemic?—Of course I had not seen other places, but, compared with the figures given for other places, I think the number of cases we had was comparatively small.

16,946. When did the disease finally cease in Nasik?—I was not there. There were a few cases after I left

in February. The last cases I have got down here are for the week ending the 25th of March 1898. There have been no cases since then until about three weeks ago.

16,947. You cannot speak of these?—No.

16,948. I think you assumed work in Bombay in the middle of February 1898?—Yes.

16,949. Which ward had you charge of?—Edward Byculla and Mazagon.

16,950. Is that a large ward?—Yes.

16,951. What is the normal population?—Between 180,000 and 185,000.

16,952. What steps did you adopt here?—Chiefly disinfection. We removed patients to the hospital, and contacts; but of course the contacts are a very different matter in Bombay to what they are up country.

16,953. Where did you remove the contacts to?—To camps; we had different camps; I had one large camp in Byculla, and there was a camp attached to the Mahratta Hospital, to which a number of people went.

16,954. This measure was interrupted, was it not?—Yes. It was interrupted on the 9th of March 1898.

16,955. How was that?—It was interrupted by a riot.

16,956. Subsequently to the riot what has been the procedure?—We continued much the same procedure, except that the wholesale evacuation of large chawls was lessened. Of course that could not go on after the rains began, because almost all vacant spaces for camps are on low-lying ground, where the water lies.

16,957. I think we already have the figures showing the extent of the epidemic at this time?—Yes.

16,958. That constitutes your personal experience?—Yes.

16,959. Have you any knowledge of the influence of rats in the propagation of the plague?—No, I have not.

16,960. You have had considerable opportunity of observing the plague in different places. Can you associate its extension anywhere with rats?—No, I have never been able to trace the spread of infection to rats.

16,961. Have you any opinion on that subject based on what you have observed?—No, I have had no experience of rats at all.

16,962. Have you seen plague extend itself where there appeared to be no conveyance by means of rats?—We had no signs of conveyance by means of rats in Nasik at all.

16,963. You had no appearance of dead rats?—We found dead rats occasionally.

16,964. Not in large numbers?—No, and we had no means of having them examined.

16,965. They were not examined bacteriologically?—No; but they were certainly not found anywhere there in large numbers.

16,966. How, then, do you think that plague is extended or carried from one house to another, or from one district to another?—As far as I can see it is brought in by people who are infected. People come from infected places and live in clean houses, and apparently after some while they infect the houses. We had imported cases from time to time in Nasik. The first case I saw was in March 1897. That was an imported case, The house was disinfected and nothing more happened. And then there were similar cases from time to time up till October, when we got indigenous cases.

16,967. In your experience, if you get early information of an imported case, and deal with that case as you have described, plague may not become indigenous in a town or village?—I think so if you get early information.

16,968. Early information seems to be a matter of great importance?—It is.

16,969. As to other methods to adopt in dealing with an epidemic, upon what do you place the greatest trust?—Evacuation and cleaning.

16,970. Cleaning, including disinfection?—Yes, including disinfection, but also including cleaning the surroundings.

16,971. Do you generally find the surroundings very unhealthy?—Yes, particularly in Bombay.

16,972. In Nasik?—In Nasik they are not so bad. Of course you do not get so much water lying about here; it is not so damp.

16,973. What kind of houses are they in Nasik—in the plague district?—In Nasik itself there are all kinds of houses; there are very poor houses. Plague began in the south.

16,974. Are they small houses?—Yes, many of them.

16,975. One floor?—They are chiefly one floor.

16,976. Of how many chambers does a house consist?—Two or three, sometimes; often there is only one room.

16,977. Generally speaking did you find that the worse the houses in a district, the more prevalent plague was?—No, I could not say that.

16,978. Still, all the houses in which it chiefly occurred were of a bad character?—They were bad in some way or another. Some of the houses were exceedingly well built—the big houses, but they are dark, badly lighted, and badly ventilated.

16,979. Is there much overcrowding in Nasik in the poor houses?—No, I do not think there is much overcrowding.

16,980. Supposing you take one of these houses, consisting of one chamber, how many people would reside in such a house?—Probably only the father and mother and two or three children.

16,981. How large is this chamber?—About 10 to 12 feet square.

16,982. This is undoubtedly overcrowded, is it not?—Of course that is overcrowded, but there is nothing like, for instance, the chawls in Bombay.

16,983. What means of ventilation would a one-chamber house have?—Practically nothing but the doorway; there is a window, but it is generally blocked up.

16,984. What was the kind of floor?—Mud.

16,985. In Bombay you think the sanitary condition is worse than in Nasik?—It is worse; because there are more people, and the overcrowding is very great.

16,986. I think you said also that they are dirtier?—Yes, they are dirtier. I am talking particularly of the chawls; the occupants have less interest in them, as they are not their own houses.

16,987. In the last paragraph of your précis of evidence you have expressed your opinion as to the methods of dealing with the disease?—Yes, it is as follows:—"As regards methods of dealing with the disease, I can speak only of evacuation and disinfection, as I have practically no experience of inoculation. In the efficacy of evacuation and disinfection I fully believe, and I would resort to wholesale evacuation wherever possible. In the mufassil such measures are naturally less difficult of accomplishment than in Bombay, and in Nasik I had the great advantage of having been in the district for some years, so that the people knew me, but even in Bombay I believe that evacuation could be largely carried out. It is difficult, of course, to deal with a large shifting population, and especially when the officers in charge and the people are mutually unacquainted, but it is not impossible, and though inoculation may assist by giving confidence, I would rather trust to evacuation with disinfection. Thorough cleaning is one of the most difficult things to carry out, and especially when an epidemic is severe. The coolie does not understand, even after months of instruction, that the whole work of cleansing a room may be nullified by his leaving a corner untouched, and the best of them will not grasp the importance of cleaning every spot inside and out. The consequence is that an immense amount of personal supervision is required, supervision over the materials and their preparation, supervision of the men and examination of their completed work, but if a house or row of houses is once thoroughly cleaned, and can be kept reasonably clean, as far as I have seen, there is little danger of plague breaking out there again. House-to-house visitation and inspection are practicable in the mufassil when the families living in the different houses are known and the absence of any one member is at once noticed, but even then it is difficult to make it effectual without considerable annoyance to the people. In Bombay, with its immense chawls full of lodgers, who have little kit, and can shift at any moment, house-to-house visitation is of comparatively little use, and the only way to discover cases of plague seems to be to employ

Mr. R. B. Stewart, I.C.S.

11 Feb. 1899.

spies, and to keep as careful a watch as possible on the cemeteries. Many cases have been discovered in large searches with troops, but such searches cause great alarm, and I would not use troops until there is good reason to believe that an area is badly infected, and other means of discovering cases have failed."

16,988. Have you anything further to say with regard to this paragraph, or as to any other point that I have asked you about?—Not as regards the value of evacuation and disinfection.

16,989. You consider they are of great value and of paramount importance?—Yes.

16,990. (*Dr. Ruffer.*) Did you find that the people at Nasik began to leave before you were informed of the presence of plague?—Not at the beginning.

16,991. They only began to leave after you arrived?—After we began to take measures.

16,992. You mention in your précis of evidence "the "newly-organised flying columns." What did each of the flying columns consist of?—The one we had at Igatpuri had an Assistant Surgeon in charge, and he had two Hospital Assistants under him. Then they brought up, I think it was, two gangs of trained coolies from Bombay, who knew the disinfection work.

16,993. How many men were there in each gang?—As far as I remember there were ten in each gang. Then, of course, we supplied other coolies who learnt the work from them.

16,994. Who prepared the disinfecting solutions, the perchloride of mercury, and so on?—In Igatpuri the Assistant Surgeon did it. It was done there by powder in the first instance; the powder was poured into the tubs and stirred up.

16,995. Did you add any acid?—Yes.

16,996. How much?—I do not know. After that, in Nasik, it was prepared chiefly by Dr. Maynard.

16,997. In how many plague houses did you find dead rats?—I could not give you the numbers.

16,998. Would the number of houses be considerable?—No. We found no rats practically; I do not think we found a single rat more than you would find in the ordinary way in walking down any street.

16,999. You say in your précis: "The only way to "discover cases of plague seems to be to employ spies, "and to keep as careful a watch as possible on the "cemeteries." What do you mean by "as careful a "watch as possible?" Do you intend to say that the corpses should be inspected at the cemeteries?—No, I do not mean the corpses should be inspected, but you should see that no body is buried or disposed of at the cemetery until the fact of the death is known to the authorities in the town. I mean, keep a watch so that people do not take away corpses and dispose of them without you knowing where they come from.

17,000. I suppose the friends give the address of the corpse at the cemeteries?—Yes.

17,001. They can give you a wrong address?—They very often do, down here.

17,002. In what proportion of the cases do they give a wrong address?—It is difficult to give any accurate figures. I should say about five per cent., but that is a pure guess.

17,003. You said that the living rooms in Nasik were 10 to 12 feet square?—Yes.

17,004. Is that exactly what you mean?—That is the case in small huts. In the better class of houses the rooms are often large and well proportioned.

(Witness withdrew.)

Lieut.-Col. G. Waters, I.M.S.

Lieutenant-Colonel G. Waters, I.M.S., called and examined.

17,005. (*The President.*) You are in the Indian Medical Service?—Yes.

17,006. What are your medical qualifications?—Licentiate of the Royal College of Surgeons, Edinburgh, and Physicians.

17,007. You are the Presidency Surgeon for the third division of Bombay?—Yes.

17,008. What duties are implied in that office?—I have to attend all Government servants in that district and their families. I have to look after a large charity school—the Byculla School; and I have two jails, one called the House of Correction in Byculla, and the other the Common Jail in a neighbouring district called Umarkhadi. I am Joint Inspector of Factories for that division also. That is an attached duty.

17,009. How do your duties bring you into relationship with plague?—Plague has attacked each of the institutions with which I have to deal, that is to say, the School, the House of Correction, and the Common Jail in Umarkhadi; but the Common Jail, beyond one case, was not attacked at all during my presence there. I may say that on the 9th of October last year, I went on sick leave.

17,010. As regards the origin of plague outbreaks, have you any knowledge, or distinct opinion?—In Bombay, the plague began in a district called Mandvi, and the houses attacked, seemed to me to have a particular bearing with regard to the direction from the opposite side of the road. The inhabitants of the higher and the more prominent houses facing the Argyle road, and in the immediate vicinity of the Argyle road, were most attacked with the plague.

17,011. Does that cause you to form any opinion as to the origin of the outbreak?—My opinion as to the origin of the outbreak in Bombay was that inasmuch as the cases occurred first in that neighbourhood, the causative factor existed there. They occurred first in that neighbourhood, and in the immediate vicinity of those houses we have the granaries, the grain stores of Bombay. They are just across the road from the places which I have been speaking of.

17,012. You think, therefore, that the granaries have had something to do with the origin of plague?—My attention was directed to the granaries from the fact that the first cases I heard of occurred in one of them, in the one belonging to Messrs. Ralli Brothers. There were 13 persons attacked. This was, I think, about the first incident of the plague—about 13 employés were attacked in one granary and they all died.

17,013. This was the first occurrence of plague in Bombay?—I think this was one of the first known incidents of the plague.

17,014. Were there any cases prior to the cases in this granary?—I daresay there may have been.

17,015. Then the cases you speak of, may not have been the first?—No, that was the first incident of which I was aware, and the next thing I became aware of, was noticing that the people in the higher houses in the immediate neighbourhood had the most plague victims.

17,016. Do you mean chawls?—We call them chawls but they are large tenements. These large tenements had victims in the upper storeys of the higher houses, and not in the lower storeys. At first, the people attacked were all in that particular neighbourhood, and then in the streets leading from Argyle road inwards towards Mandvi, the prominent houses in these streets leading off Argyle street, the houses with exposure towards Mandvi, were the houses that had the victims.

17,017. Do I understand you to imply that plague first gained a hold in the grain depôts, and then extended from them to the higher floors of the chawls?—No, I gave no theory as to that.

17,018. What do you wish us to understand?—I mean that some emanation, some fungus from the grain, blew in that direction, and affected the people who were most exposed to it.

17,019. What reason have you for supposing that the stores of grain had anything to do with the origin, beyond what you have said?—I had the knowledge that in Garhwal, on the southern slopes of the Himalayas, they had frequently outbreaks of plague, and that was supposed to be connected with the storage of grain.

17,020. What is the connection with the storage of grain, in your opinion?—My idea is that by the protracted and faulty storage of grain, grain to which damp has got access becomes attacked with this fungus, and it becomes the scene of the operations of this fungus.

17,021. What fungus is this?—I mean the bacillus—the plague germ — and generated either there, or quickened into activity by that contact, it then spreads by the wind.

17,022. Have you any knowledge as to how this bacillus is introduced into the grain?—I have no knowledge as to that. That is only a supposition, a theory, that I have formed from my own observations.

17,023. And you think the dissemination to a given spot is air-borne?—I think it is mostly air-borne.

17,024. Do you find there is a greater diffusion in windy weather than there is in still weather?—It is difficult to say in Bombay which days are windy and which not. We always have a sea breeze here.

17,025. Have you any still days?—Absolutely no still days. I have made no observation as to that.

17,026. What are the facts on which you base the idea that the bacillus in its dissemination is chiefly wind-borne?—The prevailing breeze from that point is in the direction in which most people were attacked. The breeze is not always constant from one point, but that is the prevailing breeze. There was another grain store in Kolaba, and Kolaba and Mandvi were the two points where plague started in Bombay. From those two points plague spread inwards and southwards. It It spread mostly in the direction the wind blows—from Mandvi right up by Umarkhadi and Byculla, and the two jails are in the direct line of fire from Mandvi, judging by the prevailing breeze.

17,027. Do you know whether plague extends more rapidly in breezy health camps, or in breezy temporary hospitals, than it does in the still and crowded localities of the towns?—I am not in a position to give an answer to that question.

17,028. You have no knowledge of that?—No.

17,029. You do not know whether it does or does not extend in camps?—No.

17,030. If I tell you that it does not usually extend in camps, whereas it extends very much more readily in crowded localities where there cannot be much movement of wind, how far do you think that will affect your theory?—The germs die when they are relieved from crowded localities; they are killed mostly by the sun. They are more exposed to the sun in that quarter than in the original quarter.

17,031. If they are killed by the sun how is it that infection may be carried by the wind?—I think they are all more or less diminished in vitality by the sun, but those that fall in damp places re-acquire virulent power, and so do mischief.

17,032. You have no other reasons to give for your theory than those which you have stated?—No, beyond that the first cases arose in a grain store, and the greatest prevalence of plague with the highest mortality occurred in the most exposed houses in the immediate neighbourhood, and in the direction of the prevailing breeze; and we had also something to go upon in the almost annual outbreak of plague in Garhwal, on the southern slopes of the Himalayas, where it is supposed to be associated with the grain storage under the houses.

17,033. You have nothing more to say about wind diffusion than these examples which you have given us?—Yes, I have something more to say. The Umarkhadi Jail, the Common Jail, is very close to this quarter. There was a tremendous mortality in the immediate vicinity of the jail. Meanwhile it did not attack the jail.

17,034. How did the wind blow with regard to the jail?—The wind blew right over the jail.

17,035. Towards the jail, from the infected district?—Yes.

17,036. Do I understand you to say that no cases occurred in the jail?—None for the first year.

17,037. How does that tally with your theory?—The jail is surrounded by a wall 20 feet high, and the germs are not derived from sources so high, generally, and the germs blown by the wind would strike upon the walls and not go inside as a rule. Some of them, no doubt, would fall, but those that did fall within the jail enclosure were destroyed by the sun, because in the jail I took very great care to keep the place absolutely dry, so that the plague germs could have nothing to revive them once they fell. I stopped all watering of the surface of the ground, and simply maintained as much dryness as I possibly could, and I used limewash.

17,038. Therefore wind-carried bacilli are killed by dry soil?—Not by the soil, but by the play of the sun on the dry soil.

17,039. That refers only to wind-carried bacilli?—Yes.

17,040. What about the bacilli which are not wind-carried?—I can hardly conceive of any bacilli spreading otherwise than by the wind.

17,041. You know that in crowded localities plague extends from house to house, and within houses, where the atmosphere is quite still, so that it overtakes a large area in a district where there cannot be much influence of wind?—In crowded places and narrow lanes there are many spots where the sun cannot reach. The sun is the great germicide in my opinion.

17,042. Have you any experience with regard to curative serums?—Yes.

17,043. What experience?—Plague broke out in the House of Correction late in January, and in February of 1897. That is four or five months after it had started in Bombay. I called in M. Haffkine to use his curative serum—which he kindly did—but the result, in my opinion, was negative.

17,044. Have you got the facts; will you please state what the facts are?—The facts are that as many died who were treated with the serum, as who were not treated with the serum.

17,045. What was the total number?—Altogether there were 34 cases. Half of them recovered. To put it shortly there was no beneficial result to speak of from the curative serum.

17,046. What was the incidence of the plague among these people, how many were affected?—Thirty-four people were attacked with plague and 17 died.

17,047. The result was that 50 per cent. recovered?—Yes, 50 per cent. recovered.

17,048. That is not unfavourable, is it?—It is very favourable.

17,049. Why do you say "very avourable"?—Such a low mortality to cases is rare. The figures include those who were treated with curative serum, and those who were not.

17,050. Will you distinguish between the one and the other? I should be glad if you will give us the following information; how many cases were treated; how many cases recovered, and how many cases died?—Six cases were treated with the curative serum; three died and three survived.

17,051. The result was unsatisfactory?—The curative treatment was unsatisfactory.

17,052. Will you give us any information you possess from your own observation with regard to inoculation?—From my own observation it was distinctly successful.

17,053. Can you give us the facts?—There was only a very small field to work on, because plague stopped suddenly in the jail.

17,054. Stopped after inoculation, or before?—The plague stopped in the jail altogether amongst the non-inoculated as well as amongst the inoculated. It stopped quite suddenly. There were 164 persons inoculated in the workhouse, including the jail staff, and there were 191 people who were not inoculated.

17,055. How many cases of plague occurred in these two places, in the workhouse, and in the jail?—There were 34 cases altogether.

17,056. How many cases occurred among the inoculated?—Among the inoculated there were only five cases, and two deaths. Mr. Haffkine very rightly cut off three of the five because they showed plague the day after, or two days after, inoculation. They never recovered from the fever of inoculation.

17,057. How many deaths were there among the non inoculated?—Among the non-inoculated were 12 deaths.

17,058. How many cases of plague occurred before inoculation was commenced in these places?—There were 17 cases before that.

17,059. Then out of the 34 there were only 17 which occurred after the inoculation?—Yes, that is so.

Lieut.-Col. G. Waters. I.M.S

11 Feb. 1899.

17,060. How many of the 29 cases among the non-inoculated occurred before inoculation had commenced?—I think only three. After the inoculation we had 12 deaths among the non-inoculated—and only two, really, amongst the incculated, if you cut off, as Mr. Haffkine did, the three that had plague the day after they were inoculated.

17,061. Can you tell us the ages of the people?—This will be given by Mr. King, Assistant Surgeon in the House of Correction.

17,062. (*Dr. Ruffer.*) I am not quite clear with regard to your figures. You had 327 prisoners, of whom you inoculated 164?—Yes.

17,063. Are these your own figures, or M. Haffkine's figures?—They are all the same.

17,064. In his evidence M. Haffkine says, 154. I want to know whether it is a misprint, or whether it is not?—I think M. Haffkine's figures are correct. There were other persons inoculated besides those M. Haffkine counted in the jail. There were some people in the House of Correction, and the staff.

17,065. How many in the House of Correction and the staff were inoculated? Perhaps by adding those to M. Haffkine's figures, we shall get yours?—Assistant-Surgeon King was asked by me to give the evidence required.

17,066. All the inoculations were made on January 30?—Yes.

17,067. Could you tell us the dates of the various cases of plague among the inoculated?—There were three attacked, and three died, amongst those who were inoculated on the 30th January.

17,068. I want the dates of these attacks?—It was like this: they were inoculated on the 30th January, and the inoculation fever merged into the plague fever: there was no differentiation between the two.

17,069. I want to know where the buboes were in the three cases in which the inoculation fever merged into the bubonic fever. Also, the ages of these three people, and the ages of all the prisoners?—Mr. King I have asked to give this evidence.

17,070. When was the next case among the inoculated?—There were the three cases on the 30th, which I have given you. Then there was one case on the 31st, among those who were inoculated. That person recovered.

17,071. What was the age of this person; and what was the position of the bubo?—26 years. The bubo was situated in the right axillary region.

17,072. Was there any other case?—The other case among those who were inoculated occurred on the 6th of February. That case also recovered.

17,073. Were there any other attacks among the inoculated?—Not besides the three. M. Haffkine cut the cases I mentioned out of the returns altogether, because they occurred continuously with the fever of inoculation.

17,074. But did the last two cases die?—Yes, besides the three that he excluded.

17,075. I will read to you what M. Haffkine says: "On the 31st January there were two cases of plague "amongst the non-inoculated lot, of whom one proved "fatal, and there was one case amongst the inoculated, "who recovered. On the second day after the "inoculation, on the 1st February, there was one case "amongst the non-inoculated that proved fatal, and "there was no case amongst the inoculated."?—That is quite right.

17,076. There were no more cases among the inoculated till the seventh day, regarding which M. Haffkine says: "On the seventh day, the 6th "February, there were five cases among the non-"inoculated, of whom one proved fatal, and one case "amongst the inoculated that ended in recovery"?—Yes.

17,077. You said it was fatal just now. That is why I wanted to know?—There were two attacks, and no deaths.

17,078. You said two attacks, and two deaths?—I was wrong.

17,079. Could you tell us whether these prisoners were under exactly the same circumstances, the non-inoculated, and the inoculated?—They were under exactly the same circumstances. I took them out myself and they were all together on the platforms.

17,080. Have you a plan* of the jail showing the cells where all the cases of plague occurred?—Yes.

17,081. Did the inoculated and uninoculated cases occur all over the jail?—Yes. (The witness explained the plan to the Commssioners.)

17,082. How many prisoners are there in each cell?—Usually there are three or four, according to the size of the cells, which vary a great deal. There are from 640 to 700 cubit feet for each prisoner.

17,083. Have you any register showing who was in each cell?—I do not think so. It would not be very easy, because there were people coming and going constantly. We had them all out on these platforms.

17,084. Can you tell us when the inoculated prisoners left the jail; have any of them left the jail?—Almost all the prisoners in the jails in Bombay are not very long-time prisoners. They are almost all in for under one year.

17,085. Can you put in a table showing where the various people were in the jail at the time of inoculation, and when they left the jail?—There were a a hundred people transferred to Ratnagari Jail, and we transferred a great many of the plague cases amongst them—the cases that had recovered.

17,086. I want to know, when did the inoculated people leave the jail. How long did you have them under observation?—Mr. King will give this information.

17,087. Did you hear of any deaths amongst the inoculated and non-inoculated after leaving the jail?—I have no knowledge of them after leaving the jail.

17,088. (*Prof. Wright.*) I believe there was another epidemic of plague in your other jail; can you tell us about that?—That was in the following year—1898.

17,089. Could you give us the particulars of that epidemic? Inoculations, also, were performed in connection with that epidemic, were they not?—Yes.

17,090. Where you in charge of the jail at the time?—No; I was on furlough. I, however, have the details here.

17,091. Where did you get the details from?—I got them from the jail records. I have a statement here with regard to the plague epidemic.

17,092. Who was in charge of the jail at that time?—There were two. One was Dr. Barry, appointed to act for Dr. Collie who was appointed to act for me. Dr. Barry was at the jail at the time.

17,093. Where is Dr. Barry now?—He is on furlough.

17,094. Is he out of India?—Yes.

17,095. (*Dr. Ruffer.*) Did you mention anybody else?—Surgeon-Major Collie.

17,096. (*The President.*) Where is he?—He is in Matheran.

17,097. (*Prof. Wright.*) You say Dr. Barry was in charge?—Yes.

17,098. Is he in the Indian Medical Service?—Yes. I see the ages of all the plague cases are recorded.

17,099. Would you give us a brief summary of this epidemic of plague?—In the Common Jail there were 19 attacks in January 1898; one or two of them were attacked on the last day of December 1897, but they all lived into January 1898. Of the 19 attacks, nine died. Three of the persons who died were attacked before the inoculation was performed. Of the remaining 16 there were six deaths. The remainder recovered.

17,100. Is this a long-time jail?—It is a short-time jail—much shorter than the other one.

17,101. When did the first case occur, was the patient a prisoner who had been recently admitted to jail?—The first case had been 23 days in jail when he was attacked, on the 31st of December.

17,102. (*Dr. Ruffer.*) Perhaps the best way will be to read M. Haffkine's evidence to you, and ask you whether you agree with it. He says: "At the end of "December 1897, the plague broke out in the second "Bombay jail. There are two jails here, the Byculla "House of Correction mentioned already, and the "Umarkhadi Common Jail. Three cases of plague, all

* Not reprinted with the Proceedings of the Commission.

"of which proved fatal, occurred before inoculation "was offered to the prisoners. This was done on "Saturday the 1st of January, when the prisoners "were questioned as to their willingness or otherwise "to be inoculated. The whole number of them "volunteered. In view, however, of the novelty of "the treatment, and with the object of demonstrating "its harmlessness, and the extent to which it gives "protection, only half the prisoners were allowed to "undergo inoculation. To avoid making any special "distinction the whole of the 402 prisoners present on "that day were paraded in 10 rows, an officer was put "upon them, and every second prisoner, just as they "happened to have come and were seated in the rows, "was sent to the inoculation table and received the "inoculation. We have been emboldened by our "previous experience of the after effect of inoculation "not to refuse it to anyone who chooses to undergo "it. I mean to say, no condition of health is con-"sidered to disqualify person from being inoculated, "except his having fever or plague on him at the "time he presents himself for inoculation. By "accident, however, it happened that the officer in-"oculating noticed that a man had fever on him "when the actual injection was already performed; "his temperature was taken, and found to be "102°F. While the inoculation proceeded one "came across another man, with an exactly similar "temperature, and who was left uninoculated. "Neither of these two men showed plague afterwards. "We quoted afterwards that almost incredible inci-"dent in order to emphasize the fact that in every "respect the inoculated and uninoculated prisoners "appeared to be under absolutely similar conditions, "but for the fact of inoculation. It was agreed with "the authorities that that day being Saturday and the "next Sunday, when no prisoners were expected to "work, if any of the inoculated required rest on "Monday, the whole number of the inoculated and the "uninoculated should be given leave in order that "there should not be a single circumstance which could "be pointed out as constituting a difference in the "conditions of the inoculated and the uninoculated." Have you any personal knowledge of that?—No, no personal knowledge.

17,103. Then M. Haffkine goes on: "It is because "in this instance every second man has been taken, "and because we did not wait for the volunteers com-"ing out of the crowd, as was the case with the first "inoculation in the Byculla Jail, that I consider this "experiment as having been made in more precise "order and under stricter conditions than the first "experiment. The whole lot of the prisoners were "taken in the order in which they came, without any "distinction of any kind being made"?—The second time he did that. He took every other man. I do not understand that, because there was such a number of the inoculated. 205 were inoculated, and only 70 were left uninoculated. I did not understand how he could do that. M. Haffkine told me that he inoculated every other man, and that he inoculated 205 out of a population of 275. I do not see how that came about. This was the second jail inoculation, but the first in the Umarkhadi Jail.

17,104. (*The President.*) Perhaps it was over two periods?—No, it was only once. I asked the Superintendent about that. He told me that he could not understand that. He wished to have them all done; but he suddenly remembered that he could not get all the bad ones looked after, if they were all done, so they left 70 out of the 275.

17,105. (*Prof. Wright.*) Who is the Superintendent?—Mr. Mackenzie.

17,106. Is he still here?—Yes.

17,107. (*Dr. Ruffer.*) Then M. Haffkine goes on to say: "Not to leave out anything, I must mention the "case of two prisoners who were not willing to under-"go inoculation, and who were left alone. It happened "in two instances, out of 402 persons who were there, "that when their turn came to be inoculated, because "they were second in the row, they said they did not "wish it to be done, and these two were not inoculated. "I consider this experiment in the Umarkhadi Jail as "presenting a complete elimination of the errors "inherent to observations in human communities "generally, I mean to say from the point of view of "the precision of the conditions of the experiment, and "as regards the infallibility of the results." Is that right?—Yes.

17,108. Do you agree that plague continued for a month?—Yes.

17,109. M. Haffkine says: "The plague continued for "about a month, and on 11 different days there occurred "13 cases"?—According to my information there was a case on the 18th of March, one on the 18th of February, and one on the 10th of February amongst the inoculated.

17,110. I will read you the whole statement, and perhaps you will take a copy and work it out. This is what M. Haffkine says: "During that month a certain "number of prisoners were discharged, and others "admitted to the jail. Taking day by day the num-"ber of inoculated and uninoculated who remained in "the jail during that month of plague, from the "original group of 402 prisoners, the average daily "strength of the inoculated appears 147, and of the "uninoculated 127. The number of inoculated who "stayed in the jail all through the epidemic was "therefore larger by about one-seventh than that of "the uninoculated. All the 13 cases of plague occurred "among the prisoners of the original group who were "present in the jail on the day of inoculation, and no "cases occurred in those admitted since then. There-"fore the distribution of the cases of plague amongst "the inoculated and the uninoculated, represents the "distribution of the two original absolutely comparable "groups of people which I have described. 10 of the "13 cases were amongst the smaller number of un-"inoculated, and six of these 10 died." Is that correct?—Yes, that is correct. Six deaths occurred amongst those after M. Haffkine had to deal with the jail, six deaths occurred among the non-inoculated.

17,111. "There were three cases among the larger number of 147 inoculated, and all three recovered." Is that correct?—Yes.

17,112. I believe you did not see the cases, so that you cannot tell us about the symptoms?—No.

17,113. Then M. Haffkine's account is substantially correct?—Yes. I would like to read you a few remarks I made on the inoculations in the two jails. It gives the mortality from all causes, as well as from plague. It is addressed to the Inspector-General of Prisons. The remarks are as follows:—

"The Inspector-General of Prisons is aware that I gave M. Haffkine the first opportunity of publicly testing the effect of his prophylactic serum, on the occasion of the outbreak of plague in Her Majesty's House of Correction. He will also remember that I took this responsibility on myself, as I did not see that he, as a layman, could authorise me in this regard. The Surgeon-General afterwards made it clear to me that his sanction to such dealing with the prisoners would not have been accorded. Fortunately the matter was entirely in the hands of the Inspector-General of Prisons; and I was aware that Mr. Filgate would support any measure that I could show reasonable grounds for adopting.

"The field of observation of the result of inoculation in the House of Correction was contracted by the speedy cessation of plague on the establishment of dryness within the residential portion of the jail. Still, the result achieved encouraged the prosecution of the work of inoculation, and thus eventually it obtained a wide acceptance. It has, indeed, succeeded beyond what my experience of it in the House of Correction led me to expect. And I had no further opportunity of personally observing its value as a prophylactic during my absence on sick leave. However, my doctrine of dryness as the most effective preventive of plague was not in accordance with the belief of those who successively held my appointment, and these gentlemen pursued quite a different plan, with the result that the Common Prison, which had hitherto almost completely escaped attack, despite its situation in the midst of the most severely plague-stricken spot of Bombay, became the scene of an outbreak of the disease. On this occasion recourse was had to prophylactic inoculation. I must here say that three prisoners were attacked before inoculation was adopted, and so they should be left out of account in judging the result of preventive treatment. Besides these three there were sixteen prisoners attacked with plague in the Common Prison in January of last year, and of these six died. Of the inoculated, four were attacked, and none at all died. I attach hereto a detailed statement*

* The statement referred to was not put in by witness. *See* statement put in by Mr. Mackenzie (App, No. LIX. in this Volume).

Lieut.-Col. G. Waters. I.M.S.

11 Feb. 1899.

of the men attacked, of deaths and recoveries. The three asterisks indicate the cases which preceded the inoculation, and which I have left out of account. I should add that a second inoculation was performed just four days before I returned to duty early in July last year; 205 persons were then inoculated, and only 70 left untouched. The result of this inoculation, curiously enough, was that one case of plague occurred among the inoculated, and the convict in question was transferred to the Arthur Road Plague Hospital, where he recovered; and two other minor cases occurred among the inoculated, and none at all among the other inmates of the jail, who already greatly outnumbered the remnant of the inoculated, the Umarkhadi Jail being a short-term one. By this time I had been three weeks on duty since my return from leave on the 9th July, and I had meanwhile put the jail back under my own plan of plague prevention. That is to say, I discontinued the practice described in the subjoined letter of the Superintendent of the Jail, and resumed my own simple plan of keeping the premises as dry as possible with pans of burning charcoal.

"'With reference to your enquiry as to the measures adopted to prevent the occurrence of plague in this prison during your absence on sick leave from 9th October 1897 to 9th July 1898; I have the honour to say that the practice of burning fires in the sleeping quarters was discontinued as superfluous, and that the precautions you took to maintain a thorough system of dryness and freedom from damp were quite departed from; the entire prison was frequently flooded with lime-wash, and twice daily, morning and evening, the sleeping rooms and the whole of the quadrangle of the prison were sprinkled with disinfectants. The entire prison, it may be said, was, in consequence of this application of moisture, in a condition of perpetual dampness, perhaps more particularly in places where the direct heat of the sun could not penetrate. It would not be out of place, I think, to mention here that in addition to the eighteen deaths which occurred under this régime, there was an abnormal number of prisoners constantly unfit for hard labour from sickness.'

"Lime-washing was also had recourse to at first, but finding that the subordinate jail executive could not be trusted with seeing that the lime-washed cells were properly dried with burning charcoal before they were again tenanted, I discontinued it, and for the last three months my whole concern has been to keep the working and sleeping quarters of the jail absolutely dry, and for this purpose I allow the sun's rays full scope, and where these cannot penetrate with force I have charcoal burnt, morning and evening, for the space of two hours each time. In my report on the outbreak of plague in the House of Correction early in 1897, I stated that that occurrence was due to my inability to restrain the dampness of the residential portion of the jail. And it was seen that when the dampness was obviated by the cutting off of the water outside the residential yard, the epidemic quickly—indeed, I may say abruptly — subsided. In that same report I remarked that no plague appeared, to speak of, in the Common Jail, because no water whatever was then delivered in the residential yard, and so I had no difficulty in keeping the place scrupulously dry. As I have said, however, this plan was not in operation during my absence on sick leave. My system was then replaced by one of which the daily sprinkling of the residential yard and sleeping quarters with a liquid disinfectant was a prominent feature. I here subjoin a tabular statement of the medical history of the Common Jail throughout the year; the first six months being under the régime which was not mine, and the second half of the year under the plan which was altogether my own.

Population - -	413·5	406·2	499·5	559·3	397·5	306·9	300·7	368·1	401·6	382·9	387·2	341·9
Months - - -	Jan.	Feb.	Mar.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Deaths - - -	8	2	2	2	2	2	0	1	0	1	0	1

"This shows a mortality of 18 in the first six months of the year (9 being plague cases) and only three in the last half of the same year. I am inclined to think that some of the cases of the remaining nine partook also of a pestilential nature; and this view of the case is strengthened by the fact that a second inoculation was deemed advisable at a short interval before my arrival in July last year. I would here, however, say that I do not for a moment wish to imply that the system pursued in my absence was not undertaken with a high sense of duty. And though it is my business at this moment to discriminate, I wish at the same time to put disparagement far from me. I specially wish this to be well understood, as I am given to understand that the measures in question had the approval of the Surgeon-General. I have no wish to do other than what is just and courteous to all men, and I therefore hope that my remarks on the course pursued by others shall be held altogether free from prejudice to anyone. I only wish to place in relief the fact that my plan of the strictest maintenance of dryness arrested the plague in the House of Correction in the Spring of 1897, and kept the Common Jail free from plague up to my departure on sick leave on the 9th October 1897; and that during my absence moist disinfectants were freely used in both places, with the result that there was a reappearance of plague and grave mortality in the House of Correction, and a fierce outbreak of the pestilence in the Common Jail, where it had not previously appeared. I would here say that plague seems to become weaker and weaker in successive years in any place attacked. And that it only broke out in the Common Jail in the second year of its prevalence, despite the strongly plague-stricken environment of the jail in question, shows that the means adopted for its prevention in the first year of its prevalence were effective, whilst the measures conceived for its prevention in the second year were abortive. This view of the case is further strengthened by the fact that the resumption, in July last year, of my simple plan of dryness, called such a decided halt in the mortality of both jails.

"Returning to the question of inoculation, I find that 138 inmates in the House of Correction were thus dealt with on the 3rd January 1898, there being then 128 other prisoners in that jail who were left untouched, and who thus served test purposes. Almost the whole of the 138 were inoculated after a short interval. As will be seen from the following statement, there were 11 deaths in the House of Correction in the first six months of the year.

Population - -	276	289	333	328	308	286	274	273	270	254	284	333
Months - - -	Jan.	Feb.	Mar.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Deaths - - -	Nil.	1	4	4	1	1	Nil.	Nil.	1	Nil.	Nil.	1

Total Number of Deaths - - - 13.

Total Population - - - - 3508.

"Of these 11, there was one case, that of Rama Gunpal, who had been inoculated two years running; his death was due to phthisis. There were altogether three cases of plague, two died and one recovered; all three were not inoculated. The remainder, nine, still left an enormous figure for the six months mortality of a small jail, and I may add, that of these nine cases, four were suspected at the time to be plague cases,

only they lacked pathognomonic plague phenomena, and were therefore not declared to be plague cases. It will still be observed that the mortality mainly decreased in March and April; and it should be noted that on the 7th of January 1898, the water which all the time since January, 1897, had not been allowed access to the residential quarter of the jail, was again let on, and remained on, till I stopped it early in July last, and at the same time had recourse to the burning of charcoal to overcome the dampness and keep the place as dry as possible. I here subjoin Mr. Hall's account of what was done in my absence.

'MEASURES adopted for the PREVENTION, &c. of PLAGUE in the HOUSE OF CORRECTION during the period 16th October, 1897 to 15th July, 1898.

'From October to about the end of December 1897, white-washing and the burning of charcoal fires were continued. In the early part of January, 1898, the medical officer — Major Collie — recommended that quarters for the warders should be provided, that portions of the roofs of cells should be removed to admit sunlight, and that the white-washing should be more frequent.

'About the 7th January, 1898, the medical officer—Major Barry—recommended that, in addition to white-washing the walls, the floors of all the cells should be whitewashed twice a week, that the drains and latrines should be flushed with a deodorising antiseptic, and that the same solution should be sprinkled about the yards of the prison. The clothing and bedding of the prisoners was also to be steeped once a week in the antiseptic solution and suspected admissions were to be washed with carbolic soap. These measures were continued until the 14th June, 1898, when they were discontinued on the recommendation of the medical officer—Major Collie. The water supply, which was let in to the rotunda pipes about the early part of January 1898, was cut off about the end of July 1898, at the request of the medical officer—Lieut.-Colonel Waters.

W. HALL.
Superintendent H.M's. House of Correction.'

"As a result of the change from the wet to the dry system, a glance at the same tabular statement will show that we only had two deaths in the last six months of the year, *i.e.*, two as against 11 in the first six months of the same year. But it may be asked, was this not coincident with the general diminution of plague in the neighbourhood; and to this I answer, by no means. The plague diminished in prevalence through the hot months of April and May, and reached its minimum in the first few days of July. But it then began to rise again and displayed a fresh epidemic which lasted throughout the monsoon, reaching its maximum in October. Taking the two jails together, we get a mortality of 29 in the first six months of the year, and only five in the last six months of the same year; that is, a death rate in the thousand of 41 in the first case, and only five in the second. As to how far the mortality was arrested by inoculation, it is to be observed that there was no inoculation in the House of Correction since early in January 1898, and then only half of its inmates (including jail executive) were inoculated. And in July, most of the inoculated had been released on the completion of sentence, so it cannot be at all averred that the diminished mortality of two in the last six months of the year was in any way due to prophylactic treatment. Then, as regards the common prison, it being a short term jail, few, very few of those inoculated on the 4th July, remained in prison six weeks later. Here indeed, we saw that one inoculated man was attacked with plague, and sent to the Arthur Road Hospital late in July, whilst none of the non-inoculated prisoners were at all attacked, and meanwhile the latter numbered 250, whilst the remnant of the former (the inoculated), did not amount to 100. But, I wish it by no means to be understood from this that I am an opponent of inoculation. As already stated, I was the first to give M. Haffkine an opportunity of demonstrating the efficacy of his prophylactic serum, and I am proud of its subsequent success. I was unwilling at first to give a hasty credential to prophylactic inoculation; but now that I have had occasion to review instances of its extended and enhanced effect, I gladly accord my testimony in its favour. I would, however, at the same time, point out that still more success is bound to accrue on the wide application of the principle I have enunciated, as to the obviation of dampness in, and in the close vicinity of, inhabited places. The best, the very best plague prophylactic, is dryness. This is the main thing I have learnt in regard to plague, and though it may still seem to some people a very small thing, it yet enables me to do much; and am thus in a position to hold the pestilence at bay. And be it remembered that the two Bombay jails have severally the most severely plague stricken environment of plague stricken Bombay, each jail being in the centre of localities giving the maximum of mortality."

17,114. (*Prof. Wright.*) You said the men were inoculated a second time in jail?—Yes.

17,115. Why were they inoculated a second time?—That I cannot tell you. There were 18 deaths in the first six months of the year. I have told you of nine cases of plague. Eight of those occurred in January, and one in February, and there was one other case in February. March, April, May, and June, each had two deaths; they were not put down as plague deaths, but I suspect from the second inoculation taking place so shortly before my arrival, that there must have been a suspicion that plague was at work among them.

17,116. There were about 400 people present on the 1st January?—Yes.

17,117. And the population of the jail had sunk to 275 on the 1st July?—Yes.

17,118. Then second vaccination was resorted to?—Yes.

17,119. And 205 were inoculated?—Yes.

17,120. Do you know how many of those were second inoculations, and how many were first inoculations?—There was only one inoculation.

17,121. How many of the 200 who were inoculated in January were still in jail?—None.

17,122. Had they all gone out?—Yes.

17,123. And this is a fresh series of inoculations on perfectly fresh subjects?—Yes. I have told you that the Umarkhadi Jail is a very short term jail, three months being almost the limit of residence.

17,124. These are another set of primary inoculations in jail?—Yes.

17,125. What is the result of that?—We had no result at all. One case of plague occurred amongst the inoculated about four weeks later. About 70 persons come, and 70 persons go every week to Umarkhadi Jail.

17,126. (*Dr. Ruffer.*) Could you add to your evidence the dates on which the inoculated people left the jail?—Yes, I can furnish it from the jail records, I believe. Mr. Mackenzie and Mr. King will put it in.

17,127. Will you please add to your evidence temperature charts of all prisoners who were inoculated in the Umarkhadi Jail in January 1898?—I cannot find such record on the Umarkhadi Jail; we had too much to do to have time for such record taking.

(Witness withdrew.)

Major B. B. GRAYFOOT, I.M.S., called and examined.

17,128. (*The President.*) You are in the Indian Medical Service?—Yes.

17,129. What are your medical qualifications?—M.R.C.S., L.R.C.P., and the double qualification of Edinburgh.

17,130. (*Mr. Cumine.*) You have been for about nine years Secretary to the Surgeon-General of the Government of Bombay?—Yes.

17,131. I think you have brought a map* of the Presidency with you?—Yes, I have.

17,132. You have marked on these maps at each place where plague appeared, the date of the first imported case which was reported, and also the date of the first indigenous case which was reported.

* Not published with the Proceedings of the Commission.

Major B. B. Grayfoot, I.M.S

11 Feb. 1899.

have you not?—Yes, the date of the first imported case is marked in red ink, and the date of the first reported indigenous case is marked in black ink.

17,133. Do you think the map shows that plague spread very slowly or quickly in the Presidency?—Very slowly.

17,134. Does it seem to show that a good many places escaped indigenous infection, although they had imported cases?—Yes, it does show that.

17,135. Does it show at all the length of time that it takes for indigenous plague to appear in the town after the first imported case?—The first imported case is at one end of the scale and the first local case at the other, but between the first imported case and the first local case there were a varying number of imported cases, so that, to say the period between the first imported case and the first local case is the time it takes to make a place infected is not strictly accurate.

17,136. You do not mean to say that the indigenous infection necessarily came from the first imported case?—No, it came from the whole series of infection.

17,137. Is there any relation between the number of imported cases a place has had and indigenous plague appearing in it, or does it appear from these figures that indigenous plague is not the result of a regular bombardment of imported cases, but the result of arrival of a particular kind of plague?—I cannot really answer that, because we tried to find out the number of cases of simple bubonic plague, and cases of pneumonic plague. Of course we are dealing mostly with native subordinates in all these places, and their evidence is not always trustworthy. There has been another attempt made to get the number of imported cases which took place before the first local case. At present I cannot give you statistics on that point.

17,138. You mention in your précis of evidence that an outbreak of plague has generally been preceded by high mortality?—Yes; we have noticed that in several places in the Presidency.

17,139. May not that mortality have been plague unrecognised?—I think very probably, and also more efficient registration at the time of an epidemic caused more deaths to be discovered and noted.

17,140. Will you tell us if there are any respects in which the Civil Surgeon of the Bombay Presidency differs from the Civil Surgeon in other parts of India: is he the Civil Surgeon for the district, for instance, or is he rather the Civil Surgeon of the Civil Hospital at the Sadr station?—In Bengal, the North-West Provinces and Oudh, in fact, in all the northern part of India, and I believe in Madras also, the man is gazetted as Civil Surgeon of the district, and is supposed to be and is the head of the district from a sanitary point of view. He administers the dispensaries, he is supposed to travel every three months round his district, and I believe he gets death returns and sanitary returns, etc., He has an Assistant Surgeon as his assistant, a graduate of the Punjab or Calcutta University, whom he leaves behind when he is on duty inspecting any village or town, this man being gazetted to the civil dispensary at the headquarter station. The Civil Surgeon of a district in Bengal is, therefore, more or less a travelling officer, and has the whole district under him, and an establishment to do the clerical work. In Bombay that is not so. In Bombay the officer is gazetted not as Civil Surgeon of Dharwar or Belgaum district but as Civil Surgeon of Dharwar or Belgaum. In Bengal the district is the man's first charge; in Bombay it is the station. The consequence is, in Bombay the Civil Surgeon is supposed to inspect the dispensaries in his district once a year, not every three months. He also inspects the factories, but he has none of the administration of the district under him. All that is done by the Surgeon-General in the Surgeon-General's office, so that the system is quite different in every way.

17,141. Does he receives returns of births and deaths in the villages of the district?—As far as I know, he does not. He gets no returns from dispensaries at all. They go to the Surgeon General's office. That is done for the simple reason that the Bengal system cost a great deal more than ours does.

17,142. He is the sanitary adviser of the Collector for the district, I suppose, if the Collector consults him?—Yes.

17,143. Has he any executive sanitary authority?—No, except that when he is on a tour of inspection he is supposed to send in a sanitary report if the town is of a certain population. If he sees any glaring faults of water supply or conservancy they are reported on a sanitary form which he fills up at the same time that he fills up his report of the dispensary, and sends to the Sanitary Commissioner.

17,144. If plague appeared in a village in a distant part of the collectorate it would be the duty of the Assistant or Deputy Collector to go to the place at once. Would it be equally the duty of the Civil Surgeon to leave the Civil Hospital and go off to the village?—Not under present circumstances. In fact, we find very often that Civil Surgeons find it very difficult to inspect the dispensaries once a year, because when the time comes to go to the dispensary the idea is so imbued in every one that the Civil Surgeon belongs to the station, that if some lady is ill or something is the matter with somebody's baby, he is immediately asked not to leave the station; the people do not hesitate to give such reasons for asking the Civil Surgeon to remain at headquarters. I only wish to bring out the point that in this Presidency the man's chief sphere of duty belongs to the station and not to the district as it does in Bengal.

17,145. So that although plague did break out in a distant village of the district no report about it would go to the Civil Surgeon?—Probably he would hear of it first of all from the Collector's office.

17,146. If he wished to go to that village he has no Assistant to put in charge during his absence, has he?—He can leave his Hospital Assistant, but he has no medical graduate as the man in Bengal would have.

17,147. Side by side with the Surgeon-General and the Civil Surgeon there is a Sanitary Commissioner with Deputy Commissioners and vaccinators?—Yes.

17,148. And the one hitherto has not been subordinate to the other?—That is so.

17,149. (*Prof. Wright.*) The Civil Surgeon is not subordinate to the Sanitary Commissioner?—That is so, and the Sanitary Commissioner is not subordinated to the Surgeon-General. Those two are independent.

17,150. Does not the Civil Surgeon report to the Sanitary Commissioner on sanitary matters?—He sends him occasionally a sanitary report, but he is in no way subordinate to the Sanitary Commissioner; he deals entirely with the Surgeon-General. If he inspects a town with a certain population he fills in a sanitary report which goes to the Sanitary Commissioner, and he might answer any questions that he was asked about it, but he is no way subordinate to him.

17,151. But the Civil Surgeon is subordinate to the Inspector-General of Prisons, is he not?—In his sphere as Superintendent of a jail.

17,152. Why is he not subordinate to the Sanitary Commissioner?—Because he has no work to do with him.

17,153. (*The President.*) What reports does he send to him?—He sends reports always to the Surgeon-General of the sick in his hospital and of the surgical operations and an annual report of the administration of the hospital. They all go to the Surgeon-General and the Sanitary Commissioner only gets the sanitary report spoke of from Civil Surgeons.

17,154. Has he any work of a public health character apart from vaccination?—The Civil Surgeon has nothing to do with vaccination.

17,155. Has he any sanitary work?—Only in an indirect way. He is generally on the Municipality of his station, and he is frequently made the chairman of the Sanitary Committee, and in that indirect way he does a lot of sanitary work. He is always at the disposal of the Collector. He is supposed to be the Collector's official adviser from a medical and sanitary point of view but he has no direct connection with the Sanitary Commissioner.

17,156. (*Mr. Cumine.*) When a famine comes on who takes under his charge the hospitals and the famine works, the Surgeon-General or the Sanitary Commissioner?—According to the Famine Code the Sanitary Commissioner takes all charge of famine. The Sanitary Commissioner requisitions the Surgeon-General for medical officers and subordinates, which are put at his disposal, and the Surgeon-General has nothing more to do with them until they are sent back.

17,157. That disposes of the civil medical administration. Can you tell us about the medical

administration dealing with plague?—Perhaps I ought to preface my remarks by showing the great difficulties we had when plague came. The medical services in India are recruited on this principle; Government count the sanctioned appointments and give a man for each appointment; then they add 20 per cent. for leave, and 5 per cent. for casualties. That, in total, makes up the strength of the Indian Medical Service. At the end of 1896 and in 1897, we had famine, plague, and then afterwards a frontier war with us, and it is easy to see that the strength of the Indian Medical Service was hopelessly inadequate to meet such contingencies. What happened was this. The Government of Bombay asked the Government of India for more men, and they immediately requisitioned on the Military Department for officers; all leave was immediately stopped amongst civil and military officers, and everyone at home not on sick leave was brought out at once. In that way the full strength of the service was practically in India with the exception of a few on sick leave. The Bombay Government got from the Military Department 10, 15, or 20 officers, as many as we could get, and a proportionate number of subordinates. These were posted where they were most wanted, but we did not have enough. Then the frontier war came on just as we had arranged everything, and we had to give up the men lent by the Military Department. In order to meet the difficulty of the insufficient medical aid, the Secretary of State sent out medical officers from England. To meet the difficulty of subordinates, viz., Assistant Surgeons and Hospital Assistants, we re-engaged all the old pensioned Assistant Surgeons and Hospital Assistants. We got those who would come back and put them into the easiest billets we could, to allow the younger men to go on plague and famine duty. Further we engaged everybody who had a medical qualification of any sort, and in that way we got over as best we could the frightful difficulty we had. Then if we had plague in one Collectorate and another Collectorate free, we closed as many dispensaries as we could in the one Collectorate and fed the infected area in that way. Honestly speaking, the whole medical administration of plague was more or less of a make-shift arrangement, simply because there were not enough subordinates and not enough medical officers. The difficulty of want of medical officers had been materially overcome by bringing men out from England. The medical subordinate of India, the Hospital Assistant and Assistant Surgeon, is an Indian product. There are a certain number of them and you cannot make more of them. It is now six months since I left the Surgeon-General's office, and I believe the difficulty is just the same. For three years not one of the subordinates has had leave, although as a great favour they have been allowed ten days casual leave occasionally. That is the way the principle of getting medical aid has been met. But as I say, it has been more or less of a make-shift arrangement because we have had to shut up dispensaries to send men to infected areas and never had enough subordinates to meet all demands for them.

17,158. Will you tell us about the flying columns which you organized?—In many places we did not have any medical subordinate of any kind. The original constitution of the flying column was supposed to be a Commissioned Medical Officer or an English doctor, two native assistants, if possible a female Hospital Assistant (this was very seldom possible), a couple of muccadums of disinfection, and 20 or 30 trained coolies, who had been trained in disinfection. We generally got them from men who had worked in Bombay city.

17,159. When a Collector telegraphed for them, you sent them up with their buckets and disinfectants and pumps, and so forth?—We had a regular equipment. We always tried to keep one column in advance. If we had a telegram from a Collector asking us to send up a flying column we sent it up with the coolies, and we immediately started equipping another one, teaching the subordinates, coolies, and all the rest. Of course the constitution of the flying column varied. If it was a little place we would not send a Commissioned Officer, but perhaps a medical subordinate; but the idea of the flying column was that they were to go to the place and immediately form the nucleus of a trained agency to meet with the plague, and to have all the implements and everything ready at hand.

17,160. The Surgeon-General and the Civil Surgeon inspect hospitals aided by Government, throughout the Mofassil generally. Has the Surgeon-General any right to inspect the hospitals in Bombay city?—All the hospitals are Government hospitals except one.

17,161. I mean the Municipal hospitals in Bombay city?—He has no jurisdiction over them. Of course, as a matter of courtesy, he could go and see them, but he only gets returns from them once a year for his annual report, and then he has to ask the Government to get them for him. As a matter of courtesy, if he goes to a Municipal dispensary there is never any objection made to his inspection, but as far as I know, he has no right to go and demand it.

17,162. (*Prof. Wright.*) Is there a Sanitary Board in Bombay?—Yes. The Sanitary Board consists of the Sanitary Commissioner of the Government and the Engineer.

17,163. What does the Sanitary Board do?—As far as I know, it has now assumed the advisory functions to the Government, which the Sanitary Commissioner used to have before. As far as I understand, it advises the Government on all matters, such as water supply of big towns and drainage schemes, and it collects and publishes a large sanitary report every year.

17,164. Are there only two members on the Sanitary Board?—Yes.

17,165. What happens if they disagree?—I do not know. At present, I believe, the Sanitary Commissioner is to be put under the Surgeon General, and the Surgeon General is to be made the President of the Sanitary Board, but there is nothing in black and white; it is not yet settled, I believe.

17,166. Who is the Sanitary Commissioner?—Lieutenant-Colonel Clarkson, now on furlough.

17,167. Who takes his place in the interval?—One of the Deputy Sanitary Commissioners acts for him.

17,168. On what principle are the Sanitary Commissioners selected? Are they selected for eminence in bacteriology?—Lieutenant-Colonel Clarkson has been 14 or 15 years in the Sanitary Department, he is not, as far as I know, an expert in bacteriology.

17,169. What is the Sanitary Department?—The Sanitary Department of Bombay consists of a Sanitary Commissioner and five or six Deputy Sanitary Commissioners. The whole Presidency is divided up into sanitary circles, and each Deputy Sanitary Inspector has his circle. Their chief function and most important work is vaccination. They have all the vaccination of the Presidency under them, and that, I think, forms the major part of their work. Of course, I am not in the Sanitary Department.

17,170. Who selects the men for the Sanitary Department?—As a rule the officers of the Sanitary Department are chosen by the Sanitary Commissioner himself in conjunction, generally, with the Surgeon General, who recommends to Government, because the Governor appoints every one.

17,171. Are these appointments financially desirable appointments?—No, they are not particularly well paid.

17,172. Are they sought after?—No; they used to be paid better than they are now; because they used to have a fixed travelling allowance in the old days, now that is cut. The Sanitary Commissioner to the Government of Bombay starts with Rs. 1,200 a month, and the Engineer gets Rs. 1,400, I think.

17,173. Does a member of the Indian Medical Service do himself financial damage by going into the Sanitary Department?—I would not say that.

17,174. But at any rate, he does not advantage himself?—The man in the Sanitary Department is travelling in the jungle for seven or eight months in the year, during which time he has very few expenses; he meets very few people; there are no social calls on his money, and he can, practically, live very cheaply.

17,175. But if these appointments are not sought after, I presume they are not worth having; is that the state of things?—No, I do not say that. Many men like them. I know one man who told me he would refuse any good Civil Surgeonship, because he preferred to be in the Sanitary Department.

17,176. Has a medical officer to get the Diploma of Public Health, or study bacteriology before he is admitted in the Sanitary Department?—I believe it will be so now, but the majority of men, Colonel Clarkson for instance, were in the Sanitary Department before bacteriology was an important subject or taught in the medical schools.

Major B. B Grayfoot, I.M.S.
1 Feb. 1899.

17,177. Then at present no qualification in bacteriology is required?—Knowledge of bacteriology is not made a *sine quâ non* now, but, as a matter of fact, many of the men coming in here had sanitary diplomas.

17,178. When the Surgeon-General wants advice on sanitary matters, such as disinfection, does he go to the Sanitary Commissioner?—No.

17,179. Where does he get his information from?—I think the Surgeon-General knows as much about disinfection as the Sanitary Commissioner.

17,180. I understand the Sanitary Commissioner is supposed to be a specialist, and the Surgeon General is supposed to be a purely administrative officer; does he not go to any specialist to get information on disinfection?—The Surgeon-General is the adviser to Government on all medical subjects. The last time we had to do a great deal with disinfection, we consulted M. Haffkine and Mr. Hankin, and every conceivable source we had.

17,181. But you have no official adviser?—No official bacteriologist.

17,182. Is there no bacteriology connected with the Sanitary Department?—No Government bacteriology. The only real laboratory we have is the one in the Jamsetjee Hospital; which is for the use of the Professor of Physiology and the Professor of Pathology.

17,183. And the Sanitary Department has not any laboratory at which bacteriological work can be done?—It has no experimental laboratory.

17,184. Supposing you want to know whether a particular disease spreads by air, wind, or water, or anything of that sort, whom do you ask?—We do not ask anybody. At present we can ask M. Haffkine to report on any subject, but before he came to Bombay we had nobody, and we have no institute and no Government bacteriologist for Bombay Presidency, whom we could ask to carry out a series of experiments on the life history of anything.

17,185. Has it been represented to Government that you want information and cannot get it? I presume you represent the Surgeon General's office? Has it ever been represented to Government that advice is wanted on matters of this kind?—I do not know; I am not aware that the Surgeon-General has made any special representation that he requires an adviser in bacteriology. The question has been, I believe, considered by Government, who know what is required.

17,186. Were the flying columns, of which you spoke, under the Surgeon-General?—Yes.

17,187. Not under the Sanitary Commissioner?—No. The rule was that the Surgeon General equipped them and they were sent to various places, and the medical officer was supposed to work in conjunction with the local revenue officer, that is to say, the Assistant Collector, or whoever was the head of the Civil administration.

17,188. Was the Medical Officer in charge of the flying column trained in bacteriology?—No; he was very often a Hospital Assistant or Assistant Surgeon, or anybody we could get. It was very seldom we could get a Commissioned officer.

17,189. Had you any guarantee that he knew anything about disinfection when he set out?—He knew as much about disinfection as most medical men do.

17,190. How much is that?—That varies according to the man.

17,191. No steps were taken to see that he had more knowledge of the matter than the average medical man?—No, we could not do it, because we were working at high pressure and had to take any man we could get. We had these sudden calls upon us, and our subordinates had not been trained in bacteriology. The medical officer had had practical experience of disinfection of houses with an acid solution of perchloride, and his coolies under him had been trained in the use of the wooden Chinese pumps, and all the technical details of disinfecting a house. We do not pretend they were scientifically perfect columns, but what we maintain was that they were the best means at our disposal of supplying a trained agency in those jungle places where they went.

17,192. Then these men simply knew how to use a pump and how to pour on a certain fluid?—They could not take the sweepings off the floor and tell you if there were bacilli there, but you could not expect that. As I say, they were not scientifically perfect, but they were the best we could get with the material at our disposal to meet the difficulty of plague breaking out in small places where the people know nothing. We sent Captain Leumann to Lanauli, and of course the columns were fairly good when we had medical officers going with them, but in some jungle places we only had a Hospital Assistant and perhaps 20 coolies to start the nucleus with the Mamlatdar, the village constable and the Patel.

17,193. Were these so-called flying columns reported upon by the Surgeon-General as being trained columns or did the Surgeon-General say they were not trained?—He called them flying columns; we never pretended at the time they were perfect.

17,194. Were their imperfections fully reported?—No, there was no need to do that because Government knew it as well as we did. All Collectors know the capabilities of a Hospital Assistant and an Assistant Surgeon, because they deal with them every week. If we had gone on reporting on our own imperfections in the way of all the things we wanted, we should have been reporting all day long, because when you have famine, plague, and a frontier war all on at once, you must be disorganised. In India in normal times the policy of the Government is only to have a sufficient number to do the actual work of the country, leaving a small margin for deaths and leave.

17,195. (*The President.*) These columns which you sent out were not expected to do original investigation?—No; they were just simply to meet the local requirements of the place.

17,196. They were not expected to do original investigations under the circumstances, even though they were able to do it?—No.

17,197. They required sufficient training merely to carry out the best method of disinfection?—Yes, and they were supplied with all our instructions. We issued instructions in disinfection which we had drawn up after we had had elaborate experiments done by Mr. Hankin on the question of the best disinfectant.

17,198. Supposing you had a large number of trained bacteriologists in India, it is not at all probable that you would have told off one of these men to each of the flying columns?—It is a thing I should never have thought of doing for one moment.

17,199. You spoke of the functions of the Sanitary Commissioner; he has a Deputy, I understand?—Yes, five Deputies.

17,200. Each of whom has a district under his immediate control?—Yes.

17,201. How large is this district?—The district generally consists of two or three collectorates. As a matter of fact the districts are rather large; they cannot get round their whole district during one touring season. The touring season generally commences at the beginning of October and goes on to the end of May. They have no time to go round the whole district in a year; it generally takes them two to three years.

17,202. You stated that the functions were largely to look after the water supply and large schemes of conservancy?—Any sanitary function of that kind—the ordinary advisory powers of a Health Officer at home, and on the same things that he would advise his Corporation about. He would point out obvious mistakes in the water supply. For instance, if they saw that the local authorities had placed the village latrine above the inlet where they take the water, they would point that out. They would advise on any local sanitary work, but, as I said before, I think their best and greatest work is vaccination.

17,203. Who else does sanitary work officially?—The Sanitary Commissioner and his five Deputies constitute the official Sanitary Department of this Presidency.

17,204. There is no one else officially connected with it here?—No. Every Civil Surgeon is supposed to be the medical and sanitary adviser of his Collector; that is to say, if his Collector had in his district, or in his special town, anything that he saw was wrong, he would ask his Civil Surgeon what he thought about it, and if it was sent up officially to Government it would then immediately fall into the Sanitary Department's hands. The Civil Surgeons do a lot of sanitary work because they are generally in the Municipality of their station, frequently chairman of the Sanitary Committee, and in that way they do a great deal in the way of helping the Municipalities with their advice.

17,205. Who looks after such questions as overcrowding, ventilation, and so on, in houses?—If it came under the Civil Surgeon's notice, if he saw any epidemic disease he would report it to the Collector, but there his functions would cease. He could do nothing.

17,206. Supposing there was no epidemic disease, and nothing to draw his attention specially to the condition?—He would report it once a year when he made his annual sanitary report, that in such and such a quarter overcrowding was very great, just as the Health Officer to the Bombay Municipality has for years reported that there is overcrowding and insanitary chawls in Bombay; and they still exist.

17,207. Whom would the report go to?—The report would go to the Surgeon-General's office, and when he saw it he would send it on to the Collector of the district, and request him to do anything he could to remedy it, and the probability is that nothing would be done for the lack of money.

17,208. The Collector would have the ultimate decision?—The Collector, as the head executive and revenue officer of the district, must take the initiative. The Sanitary Department have no power. They can only advise. They have no power to insist on anything being done.

17,209. Suppose the Collector does nothing and the sanitary official is still impressed with the insanitary condition, what more can he do?—He can report to the Sanitary Commissioner that he has recommended certain measures, and that nothing has been done, and the Sanitary Commissioner can refer the question to the Government.

17,210. That means to whom?—To the Governor and Council. He would write to the Secretary of the Government in the General Department, reporting the whole case, and the ultimate decision must rest with the Government whether any action is to be taken or not.

17,211. In a good many instances such reports, I believe, have been sent to the Collector?—The reports are going on all the year round on this point.

17,212. Do you know of any cases in which any action further than that has been taken?—In the majority of cases nothing further has happened; the Collector might want to do it, but he has not the money to do it.

17,213. In a good number of cases nothing has been done?—If you look up the records of the Sanitary Department of this country you will see there has been a most valuable lot of advice given with very little action, because, although the Government and everybody are most desirous to do these things, every sanitary reform resolves itself into a question of money.

17,214. Therefore, your answer is that in a large number of cases these reports have been sent in and no action has taken place?—Yes.

17,215. With regard to these cases in which no action has been taken, do you know if the person who originally sent in a report, that is the sanitary official, has done anything further?—I cannot tell you that. I do not know it within my own knowledge.

17,216. (*Dr Ruffer.*) Did you say the Sanitary Board consist of the Sanitary Commissioner and the Engineer?—Yes

17,217. How often does the Board meet?—I cannot tell you that.

17,218. Do you know of any great work or any improvements which have been the result of the action of the Sanitary Board?—I am not in the Sanitary Department and I really do not know. The only way I knew of the actions of the Sanitary Board was, that when a dispensary was to be built or anything of that kind done, it fell within the Surgeon-General's jurisdiction, and very often a reference was made upon it to the Sanitary Board and to the Surgeon-General. In that way I got to know what was going on in the Sanitary Board, but I really had nothing to do with it. And my knowledge in this regard is not complete.

17,219. Can you tell me what the total population of the province of Bombay is, roughly speaking?—About 19 or 20 millions.

17,220. There are five Deputy Sanitary Commissioners?—Yes.

17,221. How many Civil Surgeons are there?—Twenty-four.

17,222. How many dispensaries are there?—Taking the Municipal dispensaries as well as the State-aided dispensaries, I think there must be very nearly 300. We have 283 Hospital Assistants who have appointments, and then we have a reserve of 56, and in that reserve there are some who are employed in dispensaries. The reserve is supposed to be kept for leave, but now it is all employed on plague duty. We have, to quote exact figures, 296 dispensaries and there are 87 dispensaries in Native States in the Bombay Presidency.

17,223. What towns do you choose for dispensaries?—We place dispensaries in the headquarters of a district. In the Dharwar Collectorate, Dharwar is the head station of the place, and we had the Civil Hospital there; then in all the large and important towns like Hubli and Gagad and in all the Taluka towns, that is, in every sub-division of a Collectorate, we try to have a dispensary.

17,224. What is the smallest town in which you have a dispensary?—They go down to 3,000 and 4,000 people with a daily attendance of only 30 or 40 people.

17,225. Do the people get their medicines for nothing?—The medicines are supplied from the Government Medical Stores, and are paid for by the Dispensary Fund, which is made up by a grant from Government, a grant from the Local Board and a grant from the local Municipality. The poor get free advice and medicines.

17,226. Does the Civil Surgeon, the Sanitary Commissioner or the Hospital Assistant, or anyone connected with the sanitary service at all, ever visit the smaller villages?—The Sanitary Commissioner visits places of importance, his Deputies go everywhere checking vaccination returns, &c. The Civil Surgeon only visits dispensaries in his district.

17,227. What does the deputy Sanitary Commissioner examine in each village?—He has to check the local vaccinator's returns, but of course, members of the Sanitary Department can give you more minute details than I can.

17,228. What system of notification of infectious diseases have you?—We have no system.

17,229. What system of notification of deaths have you in the province of Bombay?—I think it is chiefly a matter of the police.

17,230. No sanitary officer concerns himself with deaths unless they are brought to his notice?—No, and has nothing to do with them, as far as I know.

17,231. Unless the Head man of the village chooses to report it, nothing is known?—I should imagine so.

17,232. So that plague, for instance, or any infectious disease might be going on in villages for six months without anybody being any the wiser?—That is a point I brought out. We had high mortality in many villages, and from the Surgeon-General's office we told them that there must be plague amongst them. Frequently they denied it, and then it was forced upon them afterwards.

17,233. (*The President.*) You would only know it in the event of the mortality rising above the average mortality to a distinct degree?—Yes.

17,234. And, of course, plague sometimes occurs without such a rise?—Yes.

17,235. (*Mr. Cumine.*) The village Head-men are bound to report the outbreak of cholera or small-pox, I believe?—Yes; they are bound to do it, and, as a matter of fact, cholera is almost always reported.

17,236. Supposing the Sanitary Department told the Collector that in a particular village or Municipal town there was a great deal of over-crowding, has the Collector any legal power to remedy that?—That I do not know; it is a question of the Municipal Act: I should think he ought to have, but I do not know whether he has.

17,237. Do you think he has, as a matter of fact?—I do not know what the Collector's powers in that regard are.

17,238. Do you think the Collector stands principally in need of information that a place is dirty, or in need of money and agency to make it clean?—I think that in India at the present time what is wanted is not so much trained agencies, because we have them now, but what we want is money for works. The trained agency at the disposal of the Government is quite good

Major B. B. Grayfoot, I.M.S.

11 Feb. 1899.

enough to advise for all the sanitary requirements of this country so far as I can see, for many years to come. What is wanted is money.

17,239. (*Dr Ruffer.*) Surely it would be better if you could have a system of notification and registration?—Minor details of that kind, if it can be done, might be instituted, but any large sanitary schemes, such as having a trained bacteriologist at every headquarter town, any gigantic scheme of that kind would be of no use. In every place any doctor can see what is required, from a sanitary point of view.

17,240. I should not call the notification of disease a minor detail?—Those details we might have, but any tremendous Sanitary Department such as you have in Great Britain we do not want.

17,241. (*The President.*) How long has the present Sanitary Department been in existence?—Certainly 20 years in this Presidency. I cannot tell you for the whole of India.

17,242. The great barrier for doing work has been absence of funds?—Yes, and also there are other things which are a great drawback in India. We have no Medical Act, and lots of disadvantages like that. Anybody in India can practise medicine or surgery.

17,243. Is there any immediate or early prospect of the requirements being met if there is want of funds?—I do not think there is.

17,244. Has that barrier of want of funds been found sufficient to prevent very large sums from being expended in Bombay and elsewhere during these epidemics on sanitary improvements?—I think very large sums have been spent in the epidemics of plague, and in that way the Government have done all that they could do.

(Witness withdrew.)

Mr. F. M. Gibson.

Mr. F. M. Gibson recalled and further examined.

17,245. (*Dr. Ruffer.*) The last time you were before us you gave us some evidence about the bacteriology of plague in human beings and rats, and also an account of an attempt to trace the bacillus in nature: have you anything to add to your bacteriological evidence?—I have no further evidence to add in that direction, but the investigations have been, and are still being, proceeded with.

17,246. Have you any more facts which you would like to put on record?—I have noticed recently in rats infected in Bombay an affection of the lungs which, I think, is important as an indication of how rats get the disease.

17,247. Will you describe that?—The lungs in an ordinary rat which has died of plague are usually found collapsed and pale. In the rats which I saw at the beginning of last month the lungs completely filled the thoracic cavity, and showed hæmorrhagic patches, and on section they were found to be tremendously engorged with blood. I failed to get the plague bacillus from the sputum, but it was very obviously present in the blood and the liver. I think it must have been in the sputum, although I failed to get it.

17,248. What is your conclusion?—I think it likely that these rats contracted the disease by inhalation of infected material. So far, I have found the bacillus in the blood of the rat, and also in the urine and the fæces.

17,249. How did you obtain plague bacilli from fæces?—Simply by smearing on a series of agar tubes, and isolating colonies in that way. The intestine was scorched through with a hot iron, so as to avoid contaminating with the blood in which the plague bacillus is, of course, present. Then the fæces were removed from the intestine with a needle.

17,250. How did you ascertain that the bacillus got from the fæces was really the plague bacillus?—That was isolated by smearing a sufficient number of tubes, and getting isolated colonies. Pure cultures were obtained, which were injected into rats, and the rats died of plague, and pure bacilli were recovered again.

17,251. What further conclusions do you draw from these observations?—That the rats are probably instrumental in infecting localities. I do not know how they do it.

17,252. Do you think the rats acquire the disease by inhalation?—I certainly think so in these rats which I got at the beginning of last month.

17,253. Not always?—No; these rats showed a special implication of the respiratory organs.

17,254. Have you any experiments to show that rats can be easily infected through the nose?—No.

17,255. Have you any more experiments with regard to rats becoming infected by feeding with plague cultures?—I have experiments going on, but they are not complete.

17,256. When you were here before, you said you would see whether rats contracted the disease by feeding on other rats dead of plague; have you made that experiment?—I only once got a rat which died after eating part of another rat dead of plague. It died within 10 hours of the original plague rat, and we were unable to recover the germ. Probably, I should say, it died of toxine poisoning.

17,257. They are all the experiments you have made on that point?—Yes.

17,258. Have you any other bacteriological points you would like to put forward?—I have some remarks regarding the occurrence of the bacillus in man. I found it always in the blood of dead patients and always in the sputum of patients who have died of the pneumonic form. Once I recovered it from the urethra of a patient who had died of the bubonic form.

17,259. In how many cases did you examine the urine?—Not more than five.

17,260. In bubonic or septicæmic cases?—Bubonic.

17,261. In how many cases did you find the bacillus?—In one.

17,262. Did you find the bacillus in the fæces?—No, I have never succeeded in doing that.

17,263. Did you examine the case in which you found the bacillus during life or after death?—After death.

17,264. Have you any other facts you would like to give us?—That is all as regards human beings.

17,265. (*The President.*) Have you found any bacilli in the sputum of bubonic cases?—No, only in pneumonic cases.

17,266. You have examined the sputum in many bubonic cases?—Yes.

17,267. And the results have been altogether negative?—Yes.

17,268. With regard to pneumonic cases have you found the bacilli in any excreta except the sputum?—No.

17,269. You have searched for it in the urine?—Yes.

17,270. And in the fæces?—Yes.

17,271. And you have failed to find it?—Yes.

17,272. Although in the same cases you have found it in the sputum?—Yes.

17,273. (*Dr. Ruffer.*) Have you made any other attempt to trace the bacillus in nature?—I have not completed any.

17,274. You have nothing you wish to put forward at the present moment?—M. Haffkine asked me to give some evidence with regard to the testing of the prophylactic.

17,275. Will you kindly give us your evidence as to that. In the first place, since when have you begun testing?—From December. The plague prophylactic is a broth containing chiefly albumose in solution inoculated with plague bacillus, and it is then grown for a period of from two to six weeks. Such flasks as show sufficient growth are then sent to be tested, and that was the work on which I was employed during December.

17,276, Are the flasks tested before sterilization?—Yes. The testing consists of drawing a small portion from the flask with a capillary pipette and smearing that on the surface of a specially prepared agar. It is of great importance to have the agar of a rather dense consistency and well dried. If it is not dry the growth is not characteristic, and it is difficult to see if there are foreign organisms present. Then the agar tubes are incubated in ordinary room temperature in Bombay, namely, 80° F., for three or four days. The growth of plague

thus obtained is quite characteristic. During the month of December I examined some 650 flasks, and of these, 50 were rejected as showing contamination with other organisms. That is a large number to be rejected, but it was chiefly owing to our having only a faulty form of flask with a rather wide neck. Latterly we have got into use a large flask with a very narrow neck. As showing the advantage of this I may say that the last 140 flasks which I examined showed no contamination at all. As to the nature of the contamination it was most frequently a yellow sarcina.

17,277. That is the only test which you have applied before sterilization?—Yes. After sterilization I also examined the flasks and only once found a living organism; but the contents of this flask were rejected as a result of the first test (before sterilization at 65° C.), the same contamination being present. It turned out to be a spore-bearing bacillus which had accidentally got admission. With this exception I never found a living organism in the material immediately after sterilization.

17,278. How was that examined?—It was examined in the same way on agar tubes.

17,279. Did you examine the contents of the flask which had been sterilised or the contents of the small bottles ready to be sent out?—The routine is for the decanters to inoculate an agar tube during the process of decanting a flask; every such tube is incubated for three days or more, and then examined by one of the staff of the laboratory, and the brews corresponding to those which are found contaminated are subjected to further examination with small bottles.

17,280. That has been going on since December?—Yes.

17,281. How much do you inoculate in each agar tube?—If you have sufficiently large tubes, and well dried-out agar, you can inoculate from ½ to ½ c.c.

17,282. Is that after the carbolic acid has been added?—Yes.

17,283. You have found a living organism only once?—Yes. The spore-bearing bacillus above referred to.

17,284. You do not examine each bottle separately after the prophylactic fluid has been decanted into it?—The large number of small bottles renders this impracticable, with each batch of small bottles placed in the sterilizer there was always a large flask of unsterilized broth. If this control broth remained sterile it was judged that the small bottles would also be sterile. The testing of small bottles I speak of refers to experiments carried out with a view to estimating the adequacy of the above test.

17,285. You do not re-sterilize the fluid after decantation?—No.

17,286. Have you anything else you would like to add?—That is all with regard to bacteriology.

17,287. Practically, your opinion comes to this, that Haffkine's fluid at the time it is being decanted is sterile?—Yes.

17,288. You are ready to give us some evidence on other points not connected with bactoriology, as, for instance, the detection and information of plague. We have had a great deal of evidence on that: have you anything special to put forward?—I have nothing special. I have noted, in my précis, instances of plague in relation to particular houses. I had hoped to give a complete series of figures with regard to the houses in my district as to the nature of the floors.

17,289. Can you give us the general results?—The figures are not complete, but I thought I might cite the case of two large houses which are in contiguity; one has stone or cement floors, and the other house has earthen floors, and is also densely populated, but not so much so as the first house. The first chawl contains about 300 rooms, and a population which varies from 2,000 to 2,500. Up to the 31st December 1898, two years and two months from the appearance of plague in the district, there were 18 cases of plague in that one chawl. In the neighbouring chawl, which was much smaller, there was a population of 300; that has been vacant since November 1897. It was first vacated in June 1897, and then re-occupied, and finally vacated in November 1897. There were 14 cases there in one year.

17,290. To what do you attribute the difference between the two?—There is very little difference except the nature of the floors. The races inhabiting the two houses are different—there is something to be said for that. The larger chawl is mostly Pathans and Musalmans, whereas the smaller house is chiefly occupied by low-caste Hindus, among whom plague is more prevalent.

17,291. (*The President.*) Which house had the larger per-centage of cases?—The one with the earthen floors.

17,292. (*Dr. Ruffer.*) Have you anything to tell us with regard to the floors?—With reference to disinfection in the district, I always used a half per cent. acid solution of perchloride of mercury. I think it would be better to use an even stronger acid solution. I think, considering the nature of the floors which are constantly giving up ammonia, acid is one of the most important ingredients of the disinfecting fluid. I do not think it is possible to say yet what effect this disinfection has had. In my district there were 1,344 houses. Of these, up to the 31st December last, 803 had had plague cases.

17,293. How many had plague cases after disinfection?—That would be difficult to say. All the houses in which plague cases had occurred previously would be partially disinfected, *i.e.*, the room and the neighbouring ones to it in which a case had occurred. One hundred and ninety-six had plague cases in two epidemics, and 17 in all three epidemics. The third epidemic has not run its course yet.

17,294. Are you speaking of disinfected houses?—Many of them are partially disinfected. There are 590 houses in which cases occurred in one epidemic.

17,295. Have you any evidence with regard to health camps?—The first health camp in Bombay was opened in my district about the middle of December 1897, and the average number of inhabitants in the camp was 500 during the time I was in the district. It was in the middle of an infected area. Plague cases occurred in the camp on 13 different occasions, all the cases occurring in people who had been less than 10 days in camp, or about whom I was able to obtain a history of their having slept outside the camp. It was not a segregation camp, but it was a camp in which the people had free ingress and egress. I never found that one case in the camp could be traced to another in the camp. I found that taking off the roof of the hut was an ample means of disinfection. Since I left the district in May of last year two cases have occurred in the camp in all the residents.

17,296. (*The President.*) How did these cases orignate in the camp?—The people are allowed free ingress and egress, they might get infection outside.

17,297. (*Prof. Wright.*) Before December had you ever examined the prophylatic as to its sterility?—No.

17,298. Have you ever seen a bottle sent back as suspicious?—No, they are not generally returned. I have not seen any.

17,299. You test the contents of the flask after sterilization by introducing half a cubic centimetre into an agar tube?—It is generally run directly into the tube from the flask.

17,300. Is it the first or last portion of the contents employed for the test?—It is usually in the middle.

17,301. With regard to the addition of carbolic which is made to the prophylactic, we have it from other witnesses that certain of the bottles have been found to be putrid; do you think there is any possibility of the carbolic having ever been omitted from these bottles?—I do not think so: the carbolic is added to the flask.

17,302. In testing the sterility of the prophylactic, do you dilute so as to get rid of the effect of the carbolic, or do you run the undiluted carbolized vaccine on to your agar tube?—It contains half per cent. of carbolic.

17,303. Do you think that the carbolic which is present may prevent the bacteria from growing on your agar tube?—Yes, it delays development.

17,304. But ultimately the carbolic would, you think, evaporate, and then the bacteria, if present, would grow?—Yes.

17,305. How long are the tubes kept incubating?—Four days.

17,306. Have you ever tried to dilute the carbolized vaccine to see whether you could get any greater growth upon agar than you do by your present system of testing?—No.

17,307. Is there any precaution taken to see that the bottles or corks are sterilized? Is there any bacteriological test as to their sterility?—It has been done recently, I think, but I have no information of that.

Mr. F. M. Gibson.
11 Feb. 1899.

17,308. Is not it possible that although you might be decanting a sterilised fluid into the bottles, the bottles and corks might contain contaminations and therefore the fluid you send out might have bacteria in it?—Yes.

17,309. No precaution was taken against that as far as you know?—The bottles are sterilized.

17,310. But they are not tested?—No; at least they have not been till recently. I believe some testing has been carried out recently.

17,311. You say that you think that more than half per cent. of acid ought to be added to the disinfectant which is used for disinfecting the floors of houses?—Yes. Especially if lime has been mixed with the cow dung.

17,312. Have you tested the reaction of your floor after disinfection?—No.

17,313. Why do you think ammonia is given off from a cow dung floor?—The smell of ammonia is quite perceptible in a closed room.

17,314. (*Dr. Ruffer.*) I understand that the fluid was sterilized twice, once by carbolic and once by heat?—Yes, the carbolic is added after the heating.

(Witness withdrew.)

Dr. C. Balfour Stewart.

DR. C. BALFOUR STEWART called and examined.

17,315. (*The President.*) You have been employed in the Plague Research Laboratory?—Yes, since May.

17,316. (*Prof. Wright.*) You have been employed on testing the prophylactic?—Yes, I am responsible for it. I have done all the testing since the middle of May, except for the month of December, when I was away on leave.

17,317. Between May and December what tests were you applying?—The same as we do now. A small quantity was taken out of the flask with a sterilized pipette and inoculated on dry agar.

17,318. That is before the sterilization is undertaken?—Yes.

17,319. But is the testing of the vaccine after the sterilization process a new thing, or has it been done ever since last May?—It is comparatively new to test the bottles after sterilization and after decanting.

17,320. When was that system introduced?—I cannot say. I found it so when I came back.

17,321. When did you come back?—In the beginning of January.

17,322. When did you leave the laboratory?—The last day of November, I think.

17,323. This has been introduced between the end of November and the beginning of January?—I fancy so. I have not anything to do with that. I saw what was being done.

17,324. Your duties consisted chiefly in testing the purity of the broth culture before it was sterilized and converted into vaccine?—Yes.

17,325. Have you done anything else but that?—I have made several experiments with regard to the alkilinity of the broth, and I tried to find some other albuminous substance for the growth of the plague bacillus other than peptone.

17,326. I thought you had some evidence on the purity of the prophylactic, and the condition in which it was sent out?—I have done one or two small experiments to test the tendency of the prophylactic to become putrid from air organisms falling in. For instance, I have left a bottle of prophylactic open for a month, and taken cultivations at the intervals of two or three days with certain results. After it had been left open for 15 days or so I got a few colonies in the tube, and one or two days after that I got no cultivations at all. Again, I took another cultivation three days ago. After shaking the bottle, I took some from the top of the bottle which was fairly clear, and that remained quite sterile; but a cultivation taken from a lower part —from the sediment—gave about 30 colonies which had run together. The rest of the tube was covered with debris, but no growth.

17,327. Do you think living bacteria may be present in the sediment?—I think they may, but, at any rate, this prophylactic, which contains half per cent. of carbolic acid, is not a good medium for the growth of micro-organisms. A small flask of sterile broth put at the side of that bottle of prophylactic began to smell in three days, and it was thrown away. The prophylactic is perfectly sweet now, and there is no smell although it has been open for a month. After doing some inoculations at Tarrapur on the 18th of last month, I brought back the empty bottles. When I was at Tarrapur, immediately after doing some inoculations I poured the dregs of two or three bottles into one bottle and corked it up. I took inoculations from the dregs of that bottle which contained the dregs of two other bottles. That remained quite sterile, and I have inoculated the agar tubes at intervals from that bottle, which I call bottle A. On one occasion I got about 10 colonies, and on another occasion I got three or four colonies of a red bacillus. After that I got two or three tubes with no colonies at all. Probably this red bacillus was no longer present. There are no colonies on the last tube to-day.

17,328. These are isolated experiments; have you a methodical series of experiments or have you merely certain isolated experiments?—I have two or three isolated experiments with this prophylactic.

17,329. You have not entered into any systematic investigation of a number of samples?—No.

17,330. These experiments tend to show that the addition of half per cent. of carbolic renders the prophylactic a bad medium for the growth of bacteria? — Even after keeping some bottles I decanted the dregs of several bottles into one. The bottles had been lying about, and there was a quantity of dust on their necks, but I decanted all the dregs into another bottle and adopted the same process as before. I got a few large colonies and a large number of small colonies containing tetra-coccus. They did not increase in number: the last tubes I used did not show any more bacilli than the first tubes.

17,331. What experiments have you made with regard to the possibility of finding another culture medium?—I wish to find a substitute for peptone for nutrient broth, but nothing very much really came of it. It was necessary to find something which could be easily manipulated.

17,332. You have not succeeded in finding an effectual substitute?—I found the plague bacillus would grow very well in the alkaline albumen from white of egg, but eggs, I found afterwards, were inadmissible. I tried fish and cheese and glutine and pea flour, but all those things could not be manipulated very well. The solution would not filter clear in the slightly alkaline medium, and it only filtered clear at a too high degree of alkalinity for the growth of micro-organism.

17,333. M. Haffkine says in the letter before me, "I "beg to request the favour of your kindly obtaining "that the first two officers, Drs. Stewart and Gibson, "who have been called to give evidence before the "Indian Plague Commission, be questioned in detail "as to the above operations and their results," that refers to the operation of testing the vaccine?—Yes.

17,334. Testing the vaccine before sending it out?—Yes.

17,335. Have you any experiments which bear on the purity of the vaccine?—All my experiments have been in testing the purity of the vaccine after it has left the cultivation room.

17,336. Have you any experiments on the condition of the vaccine after it has undergone the sterilizing process?—I have not done any after sterilization.

17,337. I understood M. Haffkine referred to that?—No.

17,338. (*Mr. Cumine.*) You mention at the bottom of your précis an experiment of cultivating microbes from mud floors after disinfection with perchloride of mercury. Will you tell us what the result of that was? Did you make only one experiment?—Several small experiments were made. I scraped up some mud from the floor of a house which had been recently disinfected. In one case half an hour after disinfection the mud was damp still. In another case I scraped up some mud from the bottom of a pool of disinfectant after sweeping away the water, so that the disinfectant in that case had remained on the surface of the floor

ever since it was squirted. From all those I got a considerable growth of organisms and a good many cocci. Some of the bacilli were spore-forming, and it is quite possible they might not have been killed by the perchloride of mercury lotion, but there were numbers of micro-cocci present, which being without spores certainly ought to have been killed. I looked for plague bacilli, but the means at my disposal were not sufficient.

17,339. (*Prof. Wright.*) Did you disinfect those floors yourself?—I did not do it myself, but it was done under my observation.

17,340. Did you make up the disinfecting fluid?—No. It was made up with perchloride of mercury and a salt solution.

17,341. Do you know how it was made?—It was made according to the Government formula.

17,342. You did not yourself superintend the making up of the disinfecting fluid?—No.

17,343. Then you were testing the disinfecting powers of a disinfectant of unknown strength?—Yes.

Dr. C. Balfour Stewart.

11 Feb. 1899.

17,344. And the deduction which you draw is that the disinfectant is not effectual?—Yes, with perchloride of mercury, the pistons of the brass pumps which are used become perfectly mirrored with mercury, and the grease which is used for the pump is turned into a mercurial ointment practically.

17,345. You have not made experiments to see if you could disinfect satisfactorily with perchloride of mercury?—No.

17,346. (*Dr. Ruffer.*) How did you neutralize the perchloride of mercury when you made your cultivations?—I scraped up the mud from the bottom, and then inoculated some sterile water with them, and took the cultivations from them.

17,347. But that did contain a certain amount of perchloride of mercury?—Theoretically it would.

17,348. Did you take any steps to neutralize the perchloride of mercury?—No.

(Witness withdrew.)

(Adjourned till Monday next.)

At The Secretariat, Bombay.

FORTY-SIXTH DAY.

Monday, 13th February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary.*)

Assistant-Surgeon P. V. SHIKARE called and examined.

Assist-Surg P. V. Shikare.

13 Feb. 1899.

17,349. (*The President.*) You are a Licentiate of Medicine and Surgery of the Bombay University?—Yes.

17,350. With what office have your duties in connexion with plague been associated?—I have been Medical Officer in charge of one of the segregation camps since October 1897.

17,351. Have you had the medical care of the patients in that camp?—Yes.

17,352. And have there been many patients under your charge?—There were no actual patients to be treated, because, as soon as a case developed symptoms of plague we sent it to hospital. There was general management, and such cases were to be detected as soon as they appeared in the camp. That was the chief object of a Medical Officer being there.

17,353. You have formed an opinion as to the predisposing conditions leading to plague?—Yes.

17,354. Would you express your opinion?—The predisposing conditions are those conditions that were pre-existing, and favoured the growth and spread of the infection. Thus, the subsoil of the town, including the floors of inhabited houses, was saturated with moisture and decomposing organic matter. Then there was general vitiation of the air on account of overcrowding. The climatic conditions of Bombay were also favourable for the growth of low organic life. Those, in my opinion, were the predisposing conditions.

17,355. What climatic conditions do you refer to?—The temperature and humidity of it.

17,356. Do you mean high or low temperature?—A temperature varying between 80° and 90°. That is suited for the growth of low organic life.

17,357. From where do you think the plague was introduced?—I think the plague was introduced from some of the epidemic areas outside India. I refer especially to the southern ports of China, such as Hong Kong.

17,358. You think it came from China; what is your reason for thinking so?—Because the place where plague was first observed was Mandvi. Now, Mandvi, in Bombay, is a place nearest to the docks, and it shows that the poison was imported by sea somehow or other; the only places outside India where the epidemic has been known in recent times is the southern ports of China; and also the town of Singapore, which was visited by plague in the spring of 1895.

17,359. You exclude Kumaun and Garhwal?—Yes.

17,360. Why?—I think that those places are only endemic areas for plague; no recent epidemic has been recorded in those places, because the latest dates of plague occurring in Kumaun and Garhwal are 1884 and 1886; 1884 for Kumaun and 1886 for Garhwal, and in my opinion, there is a far less chance of the disease being spread by places where it is endemic.

17,361. You exclude them because plague has not recently been present there. Have you any other reasons?—My other reasons are, because there is no direct communication between those places; they are not very important commercial towns; and if pilgrims were to travel from those places, they would take a long time to reach Bombay, as they generally travel on foot, and visit several other places on their way; so, if Bombay was infected, there was also a likelihood of several other places being infected before Bombay was infected, or along with it. But such was not the case, and, therefore, I do not

Assist-Surg. P. V. Shikare.

13 Feb. 1899.

think myself that plague was imported from endemic areas such as Kumaun and Garhwal.

17,362. Plague also visited Nasik?—Yes; but not during the first year while Bombay was affected.

17,363. How does that bear on your theory?—This way; the year 1895-6 was a sacred year, and thousands of pilgrims visited the sacred town of Nasik. If they come from all parts of India, there is a likelihood of their coming from these places also in Northern India, and of bringing the plague with them; but Nasik entirely escaped during the year, and so, I think Kumaun and Garhwal were not responsible for the plague of Bombay.

17,364. How do you think the poison has spread?—I think the poison is mainly in the soil, including the floors of houses which get mainly infected. The poison is existing there, and it probably grows in the soil, and from it it is taken into the system.

17,365. What are your reasons for supposing that the virus is in the soil?—I will read them:—Thus we know, from elements of bacteriology, that the lowest form of organic life (pathogenic or otherwise) thrive best in a medium tainted with putrefying organic matter having a certain amount of warmth and moisture in it, and removed from direct exposure to the sun's rays. Are not all these conditions fulfilled in the floors of inhabited dwellings generally, and those in overcrowded towns and cities in particular? The floor of an average native house will be found to have been made without any plinth, and therefore saturated with moisture derived both from the high subsoil water-level as well as from surface oozings. The moisture, again, is not aqua pura, but has in solution and suspension, besides inorganic substances, the products of decomposing materials derived from defective drains, where they do exist, or from a wholesale percolation of sewage water where the drains are absent.

17,366. What is your opinion as to the conveyance of plague by rats? Have you any facts bearing on that?—I have not got any facts to show. The only thing is that, as rats exist in soil and pass 20 hours out of the 24 in the soil, they are likely to be first infected; and this is observed to be the case everywhere.

17,367. What observed facts have you in regard to the incubation period; and what are your conclusions?—Of the cases of plague occurring in my camp, I have observed that the largest number was on the first day—that is, the day of admission—and nearly two-thirds of the entire number of cases developed within the first 48 hours of their stay in the camp, and this number of plague cases fell immensely in proportion to the number of days passed in camp; and there was no case observed amongst contacts beyond the 7th day. The total number of plague cases amongst contacts up to the 31st of December 1898 was 167. Of those, 52 developed symptoms on the day of admission, 35 developed symptoms on the first day, 20 on the second day, 21 on the third day, 12 on the fourth day, 14 on the fifth, seven on the sixth, one on the seventh, no case on the eighth, one case on the ninth, one on the tenth, and two after the tenth day. These three later cases—that is, those on the seventh, ninth, and tenth—were amongst re-contacts—that is, those persons who were in contact with plague cases developed in camp.

17,368. What is your conclusion with regard to the period of incubation?—I think, so far as my camp was concerned, it fell within seven days; and over two-thirds, most of the entire number of cases developed within 48 hours of admission.

17,369. How do you think the virus is introduced into the patient?—In bubonic cases, I think, the virus gets in by a process of inoculation. That is, it enters the system through some wound or abrasion or crack in the superficial structures in lymphatic connection with the particular set of glands affected. It enters the system through such wounds.

17,370. Why do you say that?—Because there is such a large per-centage of bubonic cases with buboes in the groin. I have already said that the poison is mainly in the soil; so of course, as a sequence to that, we expect a large number of cases with bubo in the groin, because the natives of India walk bare-footed, and they sit on uncovered floors.

17,371. You have had no distinct observation in which the virus has been introduced by lesions of the skin?—No.

17,372. Have you had much experience of pneumonic cases?—I have seen some, but I have not much experience with them.

17,373. Have you observed any pneumonic cases that seemed to have proceeded from bubonic cases?—No.

17,374. Have you observed any bubonic cases which seemed to have proceeded from pneumonic cases?—No.

17,375. Have you observed any pneumonic cases which seemed to have proceeded from other pneumonic cases?—No.

17,376. You have expressed the opinion that clothing may hold the virus, and thus communicate it to someone else; is that so?—Yes.

17,377. Have you any facts of your own which show that clothing, or anything but the person of a patient may convey plague?—No, no facts at all.

(Witness withdrew.)

Dr. A. Mayr.

Dr. A. MAYR called and examined.

17,378. (*The President.*) I think you hold medical qualifications from Germany?—From Austria.

17,379. Have you for some time been occupied in Bombay in assisting Professor Haffkine in plague matters?—Yes, since February last.

17,380. (*Prof. Wright.*) I believe you have something to tell us with regard to what you call the fermentation process that goes on during the manufacture of Mr. Haffkine's vaccine?—Yes. My duty has been to inoculate the fluid and prepare it. Dr. Stewart, in his evidence on Saturday, also touched upon this point.

17,381. Have you any new points? I do not know what you understand by the fermentation process; do you mean that you have examined chemically the changes which occur in the culture medium in which the plague-bacillus is grown?—No; it was a term which was suggested by Professor Haffkine. He meant certain trials about different culture media, about reaction of culture media, about influence of temperature.

17,382. Have you made some experiments in connection with the growth of plague in different culture media?—Yes.

17,383. Perhaps you would begin with the question of the reaction of the fluid. Do you find that an alkaline reaction favours the growth of the plague?—The best reaction may be very slightly alkaline, it may even be neutral, especially if there is the growth for a long time in the liquid; whereas in agar and solid medium, a little more alkalinity may be of advantage; as it seems, that during the growth, alkali, and probably ammonia, is produced, which increases the alkalinity, and interferes with the further growth of the microbes.

17,384. Have you made experiments to determine whether the alkalinity of the culture medium increases *pari passu* with the growth of plague?—Yes. It happened by chance that several times our culture liquid got directly acid.

17,385. You mean that the culture medium was acid when it was inoculated with plague?—Before it was inoculated. As it is prepared with acid not sufficient alkali was added, especially as the ammonia sometimes gives decided reaction, before the final sterilization—after heating and sterilizing, the ammonia being evaporated, slightly acid reaction remained. That happened several times. I tried reaction with litmus paper to ascertain the reason why the microbes did not grow in the beginning. I found it was slightly acid reaction. In certain cases I added a small quantity of alkali and then the growth began. In other cases I left the liquid without adding alkali, and, perhaps, after two or three weeks, a growth began to show itself; and if the reaction was tried after that, it was found to be alkaline—not very strong, but still decidedly alkaline.

17,386. Did you find that that alkaline reaction was due to the presence of ammonia?—Partly, no doubt; because, in trying the reaction with red litmus paper, it turned blue, but after being dry the blue colour disappeared almost entirely, showing thus that the

alkaline reaction was chiefly due to volatile alkali (ammonia). Further chemical investigations were not possible, as there there were no means for them.

17,387. Have you made any observations upon different culture media?—Yes. I have tried sugar, gelatine, and glycerine to the common culture media, but no advantage was to be found, especially with sugar. Sugar seems rather to interfere with the growing. No doubt the microbe grows best in soluble albuminous matter. It grows in albumose better than in real peptone; at least it shows a quicker growth—as our present culture liquid contains almost all albumose, and very little peptone.

17,388. Have you made any observation upon the accidental contaminations of the prophylactic fluid?—Yes; but Dr. Stewart referred to that matter.

17,389. Dr. Stewart told us that he had made no examination of the fluid after it had been finally sterilized?—We inoculated last year 1,200 flasks.

17,390. These experiments bear upon the fact of the occurrence of contamination before the prophylactic is sterilized?—Between inoculation with plague-germs and final sterilization.

17,391. These experiments do not bear, do they, upon the possible contaminated condition of the prophylactic as it is sent out?—No; after the inoculation with plague-germs.

17,392. That is one of the intermediate stages of manufacture?—Yes.

17,393. Have you any observations on the fluid as it is actually sent out—observations, I mean, which bear on its sterility or otherwise?—I made certain investigations lately, and there is no doubt that in certain cases a scanty growth, especially in very old bottles which are badly corked, may be found. I am making experiments on the subject at the present time.

17,394. You have no experiments you propose to put in?—No.

17,395. You have only made a few examinations?—I made a few examinations for myself, because I thought the original sterilization of the bottles might not be always sufficient. I made certain experiments, but I have no idea of giving evidence with regard to them, because they are not conclusive enough.

17,396. Is it your opinion that sterilization at 65° C. for an hour is always effectual?—Yes, as regards plague microbes.

17,397. But not with regard to others?—That refers to the original sterilization of the empty bottles in which the liquid is afterwards decanted. When the flask with the culture is heated to 66° C., there are no other microbes in it than plague microbes. All other flasks are rejected.

17,398. Have you made any experiments with Lustig's serum?—Yes; I had the opportunity, when Dr. Galeotti came here, of going to the hospital where he injected; and I observed a few cases which seemed to me of very great interest, and, perhaps, of more value than statistics.

17,399. Was the serum that you saw injected, serum that had been manufactured in Italy?—Yes, it was serum from Italy.

17,400. How many cases did you see injected with this serum?—I saw many cases. I used to go to the hospital. There were only two cases in the very beginning in which bacilli were found in the blood by microscopic examination and by the culture method. After the injection of this serum—two injections in every case—the microbes disappeared, and the patient recovered in a very short time after three injections.

17,401. Do the microbes ever disappear from the blood in cases where serum has not been given?—Such cases are supposed always to end fatally, at least, all the observers say so.

17,402. Have you yourself made any observations upon this point?—I know that Dr. Bitter states that when the blood is infected with microbes no recovery has ever been noticed. The Austrian and German Commissions stated the same. It may be that somebody else may have observed cases where plague microbes have disappeared by themselves, but I could not say anything about it. I only know that there were three cases, two of which I saw myself. I was present at the examination where the plague microbe disappeared and the patient recovered.

17,403. You speak, in your précis, of nervous symptoms improving after the injection of serum?—Yes. This is really a very common symptom, and goes sometimes together with the lowering of the temperature, sometimes it is entirely unconnected with it.

17,404. (*Dr. Ruffer.*) I wish to ask you some details with regard to the few cases in which you said that the microbes disappeared after the injection of Lustig's serum; how long had these cases been ill when you first examined the blood?—The first, on the 11th of April, was the case of a sepoy from a regiment here. He was a very strong man, a Hindu, 20 years old. He was sick one day, and brought to hospital. There was continuous vomiting and diarrhœa from the beginning. He was very delirious and agitated when brought to the hospital. He had, as is usual, to be tied down, and have a special attendant. His temperature was 104½ and pulsations 128. He had a small tumour of the spleen, and a small bubo in the right groin. The symptoms were rather alarming.

17,405. Did you make an examination of the blood?—Yes. After sterilization of the finger, a drop was taken, and coloured in the usual way. Several agar tubes were made before inoculation, and at the microscopic examination microbes, looking like plague microbes, were detected. After two days, the agar tube showed an abundant growth of pure culture of microbes, which were afterwards inoculated into the peritoneal cavity of white mice, and produced death, in one case in 26 hours, and in the other case in 24 hours. The man was injected in the morning with 20 c.c. of serum. I may state that it was the most active serum which has been brought out. The temperature went down to 102, but as the delirium did not change, he was again injected with 15 c.c. in the afternoon. On the morning of the next day he was much better. He only vomited twice during the day, the delirium had nearly passed away, and he looked quite free. In the afternoon he was inoculated a third time. Before the third inoculation another examination of the blood was made in the same way, with coloured preparations and with cultures, but no bacilli could be found. The man recovered very soon. On the 13th April—on the third day of his sickness—he was so well that he did not require a further injection. He was perfectly conscious and had no vomiting or diarrhœa. The small bubo, which was very painful in the beginning, disappeared after five or six days, and the man himself was discharged as cured after 12 days. The second case is that of a ward-boy at the Arthur Road Hospital, a very strong man about 20 years of age. He got sick during the night of the 15th of April (four days after the other man was brought there) with shivering; and then the temperature began to rise. As it was thought that he had got plague he was at once taken to the hospital, and in the morning he was shown to us. His temperature was about 100° and he had a small bubo in the right armpit. He was not thoroughly unconscious, by that I mean to say he was not delirious. He was in a kind of stupor. He did not answer any questions. An examination of the blood was made on the same day. The whole preparation was full of microbes, which looked like plague microbes. Four agar tubes were taken, and the characteristic colonies appeared. White mice were inoculated, with a similar result to that of the first case. This patient was injected for the first time at 10 o'clock in the morning with 20 c.c. In the afternoon he was somewhat better, but as no special amelioration could be noted he was again injected with 15 c.c. The following morning he was much better. His temperature went down to 90°—it was never very high. His pulse, which was rather high—130—went down to 92. His respiration, too, at first seemed to point to some complication in the lungs. A second examination of the blood was made, and no microbes could be found. The same remark applies to the agar tube. The man had a third injection of 10 c.c., and he, also, recovered very quickly without any interference. He was discharged 11 days afterwards. There was another case, but I had not the opportunity of seeing it myself. That other case ended in recovery, notwithstanding the fact that plague microbes were found in the blood. In all three cases the injections were made at the very first moment and the patients recovered very soon.

17,406. In how many cases have you examined the blood for plague microbes—not including these two cases?—Only two. I was not really employed in the hospital. I was present, but I did not make the preparations myself, as I had no microscope at the Arthur Road Hospital.

Dr. A. Mayr.

13 Feb. 1899.

17,407. Have you examined urine for plague microbes?—I have not done so myself, but I know the case of a private patient of Dr. Galeotti where plague microbes were found in the culture. That case eventually recovered after a long period.

17,408. Have you ever examined the fæces?—Yes. A short time ago I saw a case where there was extensive bleeding from the bowels, but no microbes were found. I got a cultivation, but I could not find any plague microbes.

17,409. Have you ever examined the fæces of rats?—In a few cases, but I did not make any real methodical experiments.

17,410. Have you ever found plague microbes in the fæces of rats?—No. I only made experiments in a very few cases. But I found plague microbes once in the urine of a rat, but in that case I had not the opportunity of making more experiments.

17,411. What animals do you think are more susceptible to the inoculation of plague, mice or rats?—I think mice.

17,412. In what way—what kind of inoculation?—In the peritoneum. We used to do that when we wanted to be sure—to kill the animal when we were not sure about the virulence.

17,413. Is that better than sub-cutaneous injection?—No doubt it is. It is quicker and more sure.

17,414. Have you any facts to show that rats can take inoculation through the mucous membrane of the nose?—I have made no experiments with regard to that.

17,415. Have you any experiments to show that sub-dural inoculation will produce plague?—No: but I have no doubt about it.

17,416. Nor have I; but I want to know if you have any facts about it?—No, I have not.

17,417. (*Prof. Wright.*) Do you, in connection with the preparation of the prophylactic, inoculate the flasks with plague?—Yes.

17,418. How do you get your plague cultures: do you employ a series of different plague cultures?—When there were more plague cases in Bombay, we used to get every second or third time fresh microbes from patients in the Arthur Road Hospital, from the buboes or the sputum, and carry them on agar, or peptone solution, and inoculate that. Later on, in April and May, it was difficult to get them because we had no patients. We had not, at that time, the opportunity of carrying microbes through rats, and so on, because there were very few hands there, and we had not the means of doing it. We were obliged to carry the microbe from one peptone solution to another. Once we got fresh microbes from Hubli, and at another time from Bangalore. About every month we tried to get the fresh virus. Now, we have more time, and we are not so short-handed. We are beginning to get our cultures by inoculating rats every time, and we take the microbes from the rats.

14,419. Was it your practice to test the virulence of the microbe you used?—No, the virulence was not usually tested. At that time we had no time or possibility of testing the virulence by making the injection in animals.

17,420. Do you think that sometimes you may have used very virulent plague, and at other times a non-virulent plague?—Yes, no doubt; because I remember that, when the Russian doctor was working at the laboratory, I had the opportunity of getting from him virulent microbes, as he was making extensive experiments in connexion with inoculation. He usually had a stock of virulent microbes, so I got them from him. At other times, we had this microbe and another microbe carried through one month from one flask to the other, never passing an animal, so, no doubt, in such cases the virulence was diminished.

17,421. Do you know what brews were made with virulent microbes, and what brews were made with non-virulent microbes; have you records with regard to that?—Yes. That means to say, I know such source was used for such a number of flasks. Others are, I believe, more virulent. The first set, before it was brought in a second peptone solution, ought, no doubt, to be more virulent than the later ones, which were taken, perhaps, in the tenth generation from this one.

17,422. Have you any facts to show that vaccine was more efficacious when you used virulent microbes than when you used non-virulent microbes?—I had not anything to do with the inoculation of the prophylactic itself. It seems that from outside it was stated that in some cases less fever was produced. I do not know that the fever has any very real bearing upon the immunity. That is a question of itself. I have no experience about this.

17,423. Latterly, I believe, you have been making passages through rats to increase the virulence of the microbes?—Yes.

17,424. Have you found, so far, the virulence increases by making passages through rats?—No conclusive experiments have been made till now to ascertain the increase of virulence or otherwise by passages through rats, but such experiments are being commenced. One rat which I inoculated has not died up to date. This is the third day. I made the injection on Friday, but the rat did not die, probably because our microbe was not virulent enough. I wanted the microbe which was used for our inoculation to pass it through the rat, and to get the increase of virulence; but it was not virulent at all. I took one-fourth of the culture in the test-tube, and it did not kill it. I have tried to get another microbe from the hospital. (Note added by witness on correcting proof of evidence:—The rat died the day after I gave evidence. From a culture made on agar from its heart's blood another rat was inoculated with a loop-full, and died after three days. The virulence must, therefore, have been increased in this instance.)

17,425. At the present you are making vaccine with plague microbe which is not virulent enough to kill rats in three days when you inoculate one-fourth of a tubeful?—That is so. It was, however, only one experiment. It may be that the second experiment may prove successful.

17,426. Is this the first time you have begun to increase, or to try to increase, the virulence by passages through rats; have you any previous experiments to show whether the virulence can be increased by such a series of passages?—I was helping and working with Dr. Galeotti and Dr. Vigoura, who had continually to pass their microbes through rats or monkeys to make them more virulent. I remember that Dr. Vigoura got an original microbe from us, which was not virulent sufficient to kill monkeys in three days, and it was passed twice through white mice, and then rats, and two monkeys, until the required virulence was obtained, so that the monkey died within 42 hours; whereas in the commencement there was no possibility of killing a monkey with the same microbe in such short time.

17,427. Then you do not agree with Dr. Yersin, who says that the virulence decreases in passing it through rats?—No; at least, from what I saw, we never had that experience. We always found quite a marked increase by passing it through rats and mice.

17,428. Have you seen enough to make you feel sure that the virulence of a plague culture increases when you make a series of passages through rats?—I never saw it passing through a series of rats.

17,429. How many generation of rats do you think the culture was passed through?—The one I have in my mind just now was passed through two white mice, then a rat, and then two monkeys. Then it was of the required virulence to make the culture for the serum preparation.

17,430. You have not seen a culture pass through three or four generations of rats?—No; we did not do that, because we did not want any more than that. It may be that after several generations of rats it may decrease. I will make experiments with regard to that later on.

17,431. (*Dr. Ruffer.*) Have you tried the effects of Haffkine's prophylactic fluid on animals?—Not myself; but it was made in our laboratory, and I know about it. Experiments were made on monkeys, especially with the deposit of the liquid, as it was supposed that immunity might be conferred by the deposit.

17,432. Has it an immunising effect upon animals?—I do not say it saves from a very virulent microbe; but there is no doubt the resistance is very much increased. The control animal always died, whereas the immunised sometimes survives. Whenever the immunised monkeys died, they always died much later than the other one.

17,433. Have you made any experiments yourself?—No.

17,434. Who made the experiments?—The Russian doctor who was working in Professor Haffkine's laboratory. When he was working there I saw him do it.

17,435. You are not responsible for these experiments?—No.

17,436. (*The President.* Have you any method by which you could exactly define the toxic activity of any virus you have grown?—Yes; it is to be done by inoculating a filter culture. Experiments have been made which I know of (though not performed by myself) which show that strong toxic effects are produced by filtered cultures.

17,437. I mean with the virus containing the living bacilli?—I should not say otherwise than by trying the amount which is required to kill a rat or a white mouse, as is usually done. I did not notice any difference in the growth in different media. It may be that very virulent microbes grow a little slower than the less virulent ones.

17,438. Did you adopt any process for determining exactly the virulence of any virus; have you any method you are in the habit of using?—Yes. The usual way is to have a certain culture. You take a certain amount, a loop-full, and dilute it with a certain amount of water or broth, and then inoculate a given amount. You compare as much as you want from it. If you have a microbe that kills with a quarter of a test-tube, it is supposed to be more virulent than a microbe which kills with an injection of half a test-tube.

17,439. In the case of any virus which you have examined, can you tell us what is the smallest amount that will produce death in any given animal?—I should say with what we call a platinum loop-full—even with less virulent microbes—a rat dies.

17,440. Have you made experiments with the filtrate?—Not myself; but I saw the experiments made. *Dr. A. Mayr.* 13 Feb. 1899.

17,441. You know the result of the experiment with the filtrate; you have observed the experiments?—Yes.

17,442. On what animals were the experiments made?—White mice.

17,443. On mice only?—Yes.

17,444. What is the smallest quantity of this filtrate to a given weight of animal which is capable of producing death?—I could not tell from memory. I think it is a very small quantity; about 1 c.c.—and less if the filtrate is derived from a virulent culture—killed a white mouse in 48 hours.

17,445. I understand you determine the lethality only with the liquid filtrate?—Yes.

17,446. Have you ever passed the virus through mice?—Yes.

17,447. Have you seen any cases in which the virus became attenuated, or weaker, after being passed through animals?—No, I did not notice such a thing.

17,448. Do you know if such experiments have been made in Bombay with regard to the plague bacillus or virus?—Not to my knowledge. Dr. Gibson has made many experiments with regard to rats; but I do not know anything about them.

17,449. Do you know if any experiments have been made by introducing the virus into the alimentary canal?—No, I do not—only by way of feeding. I believe it has been done here by Dr. Gibson, but he has had no positive results that I know of. I believe it has been done by several other observers.

(Witness withdrew.)

Captain C. J. R. Milne, I.M.S., called and examined. *Capt. C. J. R. Milne, I.M.S.*

17,450. (*The President.*) I understand you are conducting investigations in the laboratory here in connection with plague?—Yes, in M. Haffkine's laboratory.

17,451. (*Dr. Ruffer.*) Would you read to us your rules for sterilising the culture flasks?—They are as follows:—

"1. All cultivation flasks ready to be sterilised are placed by the testing officer in the inoculation room on a special table designed for that purpose, and having a label pasted upon it, "Flasks ready for sterilisation."

"2. The flasks are to be transferred into the sterilisation room by the sterilising officer himself, or by his assistant under his immediate supervision.

"3. Only the precise number of flasks ready to be put immediately into the sterilisation tub should be removed from the inoculation room. Any flask which cannot be put into the sterilization tub immediately should be replaced into the incubation room. On no account should unsterilised cultivation flasks be allowed to remain in any part of the laboratory except the incubation room.

"4. A label to be made out for each flask, stating its number, the quantity of prophylactic it contains, and adding the word 'heated.' The date of heating, however, must not be entered on the label till the flask is removed from the hot-water bath and from the cooling tub.

"5. The sterilising officer further puts his initials in red ink on the original label affixed to the flask.

"6. Place the new labels on the plug of the flask and fix the paper cover on the mouth.

"7. Put the cultivation flasks, together with the 'control' flask, into the water bath, and mark in the special note book kept for the purpose the time when the thermometer in the 'control' flask shows 65° C. Leave the flask in the tub for one hour counting from that moment.

"8. On the expiration of the hour remove from the bath and cool.

"9. The original label of the flask to be examined, and to ascertain that it got either detached in the hot-water tub, or that the red ink of the initials shows the effect of the hot water. The new labels to be now removed from where they have been resting on the plugs, the date of heating marked on them, and the labels themselves pasted on the sterilised flasks.

"10. Note the quantity of prophylactic in c.c. in each flask, and add carbolic acid in the proportion of one-half per cent."

17,452. How do you measure the quantity in each flask?—Originally, before the flasks are inoculated, the amount of c.c. is placed on each flask, generally 1,200 or 1,500 c.c. That remains on the flask till it comes to the sterilising officer, who makes a note on his new label of the amount. The rule goes on: "The total quantity "of carbolic acid added to each flask to be marked on "the label."

"11. Mark the fact of carbolising, and the date on which this was done, on the label.

"12. In the book kept for the purpose, enter the date of heating and carbolising against the numbers of the flasks heated and carbolised in the respective columns, and state the actual amount of pure carbolic acid added.

"13. Flasks are now ready for decanting, and should be placed in the special cupboard for the decanting officers."

17,453. How do you add the carbolic acid?—A bottle of carbolic acid is sterilised and sterile pipettes are taken on which the quantity is marked in c.c.

17,454. What strength of carbolic acid do you use?—Pure carbolic acid: the ordinary carbolic acid that we get from the medical stores here, and we sterilise that and use it.

17,455. How long have those rules been applied?—The rules were actually in existence when I came to the laboratory, but the modification in the amount of carbolic acid added took place about four months ago; we used formerly to use one quarter per cent.

17,456. What are your rules for decanting and testing the fluid after sterilisation?—They are as follows:—

"1. The decanting officers to take the flasks from the cupboard where the flasks that have been heated and carbolised are kept.

"2. Examine closely the label, and do not proceed to decant till you learn from it (*a*) the fact of its having been heated and carbolised, (*b*) and the date on which these processes were done.

"3. Having satisfied yourself of this, put your initials on the label.

"4. Provide yourself with the necessary apparatus for decanting, a stand, a pair of forceps, a clip, sterilised bottles, a sterilised syphon, and sterile agar tubes."

17,457. How do you sterilise the bottles?—The bottles are sterilised in a large steriliser; they are first carefully cleaned, and corked, and we have pieces of

Capt. C. J. R. Milne, I.M.S.

13 Feb. 1899.

paper tied over the corks, and then they are sterilised in bulk. We generally sterilise about 1,000 at a time.

17,458. Are they sterilised with the cork in the bottle?—Yes.

17,459. By steam?—Yes.

17,460. At what temperature?—I am not positive as to the temperature; I have not charge of that department.

17,461. Please continue the rules?—"5. Heat carefully the neck of the flask to be decanted as far as "it can be done without cracking the glass, and passing "the flame of the burner at the same time over the "surface of the plug.

"6. Fix the flask on the stand.

"7. Sterilise the glass of the syphon to be introduced into the flask by passing it several times through the flame of a Bunsen burner."

17,462. How long is that glass that has been introduced into the flask?—There are two parts. There is a long part which is put into the flask, which is about 12 to 14 inches long, and then there is a piece at the end about three or four inches long. There is only a piece of rubber tubing between the part inserted into the flask and the glass tubing at the end of the syphon, and on this rubber the clip is placed.

17,463. How do you sterilise the whole of it?—The syphons are generally sterilised at the same time as the bottle.

17,464. I suppose you plug the syphons?—Yes: "Next having sterilised in the same way the ends of "the forceps, seize the plug at the mouth of the flask "with the latter, and remove it partially, and introduce "the syphon, finally pushing back the plug in place."

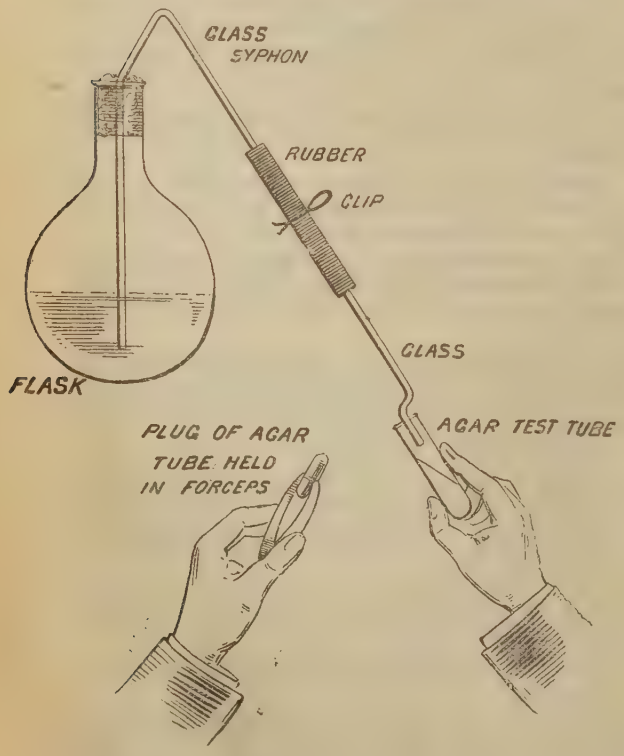
17,465. How do you fix the syphon into the flask—with an india-rubber cork?—No; we remove the cotton wool block, and insert the syphon into the flask by the edge of the cotton wool block.

"8. Fasten the clip in position on the syphon.

"9. Immediately before sucking shake the fluid with its contents well round.

"10. A suction tube (short rubber tube provided with a glass mouthpiece) is next fitted on to the end of the syphon hanging out of the flask, and the prophylactic is then sucked out from the latter down to the level of the prophylactic in the flask."

17,466. How is that done; how is it sucked out? (The witness produced the following rough sketch and explained the same to the Commissioners.) Will you



please proceed with the rules?—Yes; "a current having "been thus established, the suction tube is removed "and the end of the syphon sterilised with the "burner.

"11. Before decanting the fluid into bottles, take a sterile agar tube and fix it between the thumb and forefinger of the left hand, remove the plug with the forceps and place it between the fore middle fingers of the left hand, heating gently the mouth of the tube. Sterilise the end of the syphon and allow some fluid to run through it, then carefully insert the end of the syphon into the agar tube and allow one drop of the fluid to fall on the top of the surface of the agar slant. Then remove the syphon end, and sterilising the mouth of the tube and the cotton plug, re-insert the latter in the former with the sterile forceps. Then write on the label of the tube the number of the flask, the date and your initials.

"12. The liquid is then decanted into the bottles, care being taken—

1st. To shake the flask between every bottle filled.
2nd. To see that the bottles used are all clean and free from cracks.
3rd. That the corks are well fitting.
4th. That the end of the syphon, the mouths of the bottles, and the corks are kept sterile, this being done by repeatedly using the burner.

"13. After decanting, the number, capacity of, and the number of bottles filled from each flask are entered in the book kept for the purpose, and the decanting officer's signature affixed against it. A specimen label for the bottles filled, showing the number of the flask and the date of decanting, to be also made and handed over, with the bottles, to the sepoy who seals them.

"14. After the day's work is over all emptied cultivation flasks to be shown to Dr. Milne, who will affix his initials on the labels.

"15. The flasks are then to be placed in the go-downs in charge of the go-down clerk."

17,467. How long have the rules been in existence?—The rules have always been in existence, but the modification of testing the decanted fluid on agar has been in force since the 12th December.

17,468. Were you in charge of the Department before that?—Not actually in charge of it; only assisting Professor Haffkine.

17,469. You do not know what was done before that?—Yes, I have been nine months in the laboratory.

17,470. What was done in the first instance?—We never tested the fluid before—after its sterilisation and carbolisation—but the other processes are exactly the same.

17,471. Since when have you taken to testing the fluid?—Since the 12th December.

17,472. You do not test the fluid after syphoning into bottles?—Not unless the syphoner's tubes show impurities; in that case I test the fluid in the bottles.

17,473. Could you show me how you put the cork in, and how you seal it in a bottle like *that*? Do you turn it after the cork is in and dip it in the sealing wax like *that* (illustrating with one of the bottles produced by Witness)?—Yes.

17,474. How do you shave off the top of the cork?—We do not shave off the tops of the corks at all. The cork is pushed right into the neck of the bottle.

17,475. Have you made any experiments as to the proportion of tubes that were contaminated?—I have first to explain, that in the beginning of November there was a very great demand on our prophylactic, and we had to increase our staff greatly, and we could not get Hospital Assistants and the class of people we wanted as decanters, and we had to engage clerks, and they had to be taught how to syphon properly. In the early days of the testing of the material with these tubes by the new syphoning officers, more than 50 per cent. were found to be contaminated, although the material itself was actually pure. Out of a series of 79, 36 showed sterile tubes, while 43 showed impurities which, however, at re-examination proved to be due to the defective testing by the syphoning officers, the material itself being sterile. Latterly, the proportion has become less than 1 in 20. An experiment was made on December 28th, 1898, as follows. While syphoning seven flasks, the syphoning officers were ordered to inoculate three agar tubes, thus:—

I. The first at commencement.
II. The second after syphoning into 10 bottles.
III. The third before syphoning into the last bottle.

The result is as follows: All three tubes of the first flask were contaminated; in the second flask the first

and second tubes were sterile, and the third contaminated; in the third the first and second were contaminated, and the third sterile. In the fourth and the fifth, the first was contaminated and the second and third were sterile. The sixth was like the third; the third tube was sterile, and the first and second were contaminated. In the seventh the first tube was sterile, and the second and third contaminated. Eleven of the contaminated tubes showed less than three colonies, two showed extensive growth, while eight were sterile; that is one at least from each flask. The fact that from the same flask sterile and contaminated tubes were forthcoming, pointed conclusively to faulty manipulation on the part of the syphoning officers. When the decanter's tubes showed contamination of any sort, either single or multiple colonies, bottles of the series were examined, and in no instance was a bottle found contaminated. We have examined altogether 985 series since the 12th December, and all of these have proved sterile; and there are 48 series of which the bottles are being tested, the agar tubes not being yet ready for examination.

17,476. How do you test the bottles?—The method of examination was as follows: The sealing wax having been carefully melted, the cork was prised out with a sterile forceps. A sterile pipette was introduced into the fluid, the bottle having been shaken, and a small quantity of the fluid was sucked up and successively transferred to two agar slants and to a sterile flask of broth. The bottles were then re-corked and re-sealed —.

17,477. How much was removed?—As far as I could judge I used to take about a c.c. I made a mark on the pipette.

17,478. You say you put it into sterile broth; how much broth did you use?—I think 50 c.c. of broth. I am not absolutely positive. The bottles were then re-corked and re-sealed, and the bottle with its flask of broth and its two agar tubes, and in many instances a slide of the deposit were arranged in a dark room at the ordinary temperature, and were examined after four days to 21 days.

17,479. That would account for aërobic microbes, but could you detect an anaërobic microbe?—No. I wish to submit samples of recent syphoners' tubes showing series marked "fit" since February 2nd, 1899, and also showing the contaminated tubes in the same period. These (handing a number of syphoners' tubes) are samples of syphoners' tubes which have been marked "sterile," and *here* are some impure ones. The material in the bottles, on being tested in these instances, was found to be pure.

17,480. Have you examined any old bottles of prophylactic?—Yes.

17,481. Can you give us your experience as to that?—Bottles from 125 series have been examined by myself with the assistance of Drs. Gibson and Ransome. Those series have been stored in the laboratory for a variety of reasons, such as the weakness of the brew, &c. One dates from May 1897, while two date from March 1898. The others form a continuous series of those prepared in the laboratory from August to the middle of December 1898. The bottles of each series have been kept stored in boxes or in cupboards in the dark. Of these 125, in 104 series the sealing of the bottles was satisfactory, while in 21 it was broken or had holes in it allowing the cork to be exposed to air and dust. I have stated the method of examination. The bottles are all in the laboratory now with their flasks and tubes, and they are on view. The whole of them were examined finally by Professor Haffkine and myself. In the examination of the results, where in two instances only one of the two agar tubes showed a single colony, while the broth cultivation remained sterile—this was considered accidental, and as having occurred during manipulation, but if the broth was also contaminated, although the two agar tubes showed only one colony, the bottle was marked "contaminated" and the series re-tested. In about half-a-dozen instances the broth alone has shown growth while the agar tubes remained sterile. Professor Haffkine thinks the manipulation of the sterile pipette from the two agar slants to the broth is quite liable to allow of its being contaminated during the interval. He thought afterwards we ought to have used a fresh pipette; that I ought to have inoculated the broth with a fresh pipette separately from the agar tube. In the first instance, of the 104 bottles with satisfactory sealing, 98 were found pure, and six contaminated. Of the 21 series, in which the bottles had broken sealing, one was found to be pure and the remainder contaminated. Of the six contaminated bottles where the sealing was good, in all six broth and agars were affected. Three of these were contaminated with moulds only. One had several single colonies, while in one the surface of the tubes was covered with colonies. Of these six series it has only been possible to re-examine up to date two duplicate samples, and both these have been found sterile. Of the 20 contaminated and badly sealed series, in 18 both broth and agars were effected; in two series the broth remained pure. In 14 of them the agars were covered with mixed growth, while six showed a few isolated colonies. 10 well-sealed duplicate samples of these 20 contaminated series were re-examined, with the result that eight were found to be pure and two contaminated, while in three series satisfactory samples could not be found, and all three again with unsatisfactory sealing were found to be contaminated. Of one series still a third bottle was examined with a similar result. Of the two contaminated ones from the well-sealed series, one has been re-tested for a third time and found pure. The conclusion seems to point emphatically to the contamination of bottles taking place after the material has been bottled and sealed up and being due to defective sealing. This has been taken into account for some time, and experiments are being made to substitute a more effective method of corking and sealing the bottles.

17,482. Would you show us why you think the method of sealing is unsatisfactory?—(The witness explained same to the Commissioner.) Apart from the defects in the sealing, there is also the fact that the cork gets sodden in contact with the carbolised fluid. There are thousands of them stored in the laboratory, and the corks get sodden in time, and the appearance of the sealing wax entirely changes; it gets this open appearance, not as it is at first. *Those* are newly-sealed bottles. I have a bottle here which was perfectly sealed, but it leaked between the sealing wax and the neck of the bottle, and this would account for the contamination of the number of bottles where the sealing wax was apparently intact.

17,483. Have you any other facts to tell us?—No, I have not, except that we hope to institute rubber corks for the bottles. At present we are making experiments—Dr. Stewart and I are doing them—as to soaking the corks in boiling paraffin, and then fixing them in and sealing them over.

17,484. Have you any evidence about anything else that you wish to bring forward?—No.

17,485. With regard to inoculations, I believe you have done a good many?—Yes; I have done over 800 altogether.

17,486. Have you ever seen any abscesses?—No, never.

17,487. Have you seen any severe results following the inoculation?—Never.

17,488. How many of these patients have you seen twice?—I took a series of 200 people in the jail, who were inoculated by Professor Haffkine and myself, and I examined them 7 hours after inoculation, 24 hours, and 48 hours. I took their temperatures and examined them thoroughly.

17,489. Were they all inoculated with the same brew of fluid?—They were inoculated with two different brews made at the same time.

17,490. Did you find that the same brew of fluid produced the same rise of temperature in all the patients?—No, it varied with the patient.

17,491. How much did it vary?—The lowest temperature I recorded was 99, and the highest temperature was 104·6.

17,492. What were the temperatures between these two limits; was there an average temperature?—Yes. The average of the maximum temperatures, for the three times that I took the temperatures, was 101. The average temperature for the whole lot of observations was just over 100.

17,493. We had it in evidence that a temperature of 102 is the ideal temperature?—Yes.

17,494. In these cases you did not get that?—I probably did not get every man at the time when his maximum temperature occurred.

Capt. C. J. R. Milne, I.M.S.

13 Feb. 1899.

17,495. We have been told that one of the principles of inoculation was that you should produce a temperature of 102, but if you get a difference of between 99 and 104, how can the rise of temperature be used as a standard?—In most instances we have not been able to follow out the case completely. I inoculated my servant and had him completely under observation after he was inoculated; and I took his temperature every half hour. His temperature reached 102·3; that was the maximum about eight hours after inoculation.

17,496. But supposing you take 100 cases, as you have done in the jail, and the temperatures vary from 99 to 104, how can the temperature be the standard of efficient immunisation?—My experience of the work is insufficient to allow of my judging this question accurately.

17,497. And you have no special observations bearing on that point?—No.

17,498. Have you any facts as to animals getting the disease from one another?—I generally look after the animals kept in the laboratory for experimental purposes. Within the last few weeks a number of rats, under the orders of the Municipal Commissioners, have been brought into it. Living rats and dying rats, and all sorts of rats, and I have noticed that several of the original rats in our laboratory, which were kept in cages alongside of the others, have died of plague. They must have been infected from the other rats which had been brought in. Latterly, all rats which have looked at all ill, in fact every rat brought from Bombay, has been kept in a special cage and room. Most of them have succumbed to plague within a day or so.

17,499. Do you find plague microbes in their blood after death?—If they are examined fresh, I do—heaps of them.

17,500. Does the microbe disappear very quickly?—Very quickly.

17,501. In how many hours?—One has great difficulty in getting it after 10 or 12 hours.

17,502. Does it depend on the temperature or any other condition?—I am not aware of any special conditions.

17,503. Have you examined the urine and fæces of patients for plague bacilli?—No, I have not. I have examined the urine of rats.

17,504. Have you found it there?—No; I have only examined in five cases.

17,505. How did you examine it?—In nearly all the rats which have died of plague, which I have examined, I have found the bladder full of urine. I introduced a sterile pipette and sucked up the urine and made cultures from it, but I have never found any plague bacilli, nor has Dr. Gibson, I think. Dr. Gibson and I have been working together a good deal at this.

17,506. How long have the rats been dead?—They were only just dead.

17,507. There is no doubt about their having died of plague?—Absolutely none.

17,508. Can you tell me whether you have made any experiments as to the prophylactic effect of Haffkine's fluid on animals?—No. I have started an experiment with regard to rats, but I have not yet completed it.

17,509. Have you ever injected the prophylactic fluid into animals?—Only into rats in the experiment on which I am working at present.

17,510. How much did you inject?—I injected into one rat the dose marked on the bottle.

17,511. How much is that?—It happened to be 2½ c.c.

17,512. What effects did it produce upon that rat?—The rat is still living.

17,513. Have you used the same prophylactic fluid on man?—No, not yet. I am working at that just now.

17,514. You do not know whether the rat has been protected or not?—No, that is a point I want to work out.

17,515. (*Prof. Wright.*) I understand it is the first portion which is drawn off from each flask of carbolised vaccine which you test?—Yes.

17,516. In view of the fact which Dr. Stewart told us yesterday, that contaminating bacteria cannot multiply when they are introduced into this carbolised vaccine, do you think that you have a satisfactory test of the sterility of your vaccine when you test it by introducing your undiluted carbolised vaccine on the surface of an agar tube?—I do not think it is myself.

17,517. Have you met with any bottles of M. Haffkine's prophylactic which have become putrid?—Two of the original series which had not been carbolised, were badly smelling, but on testing them on agar and in broth in the series mentioned, they were found sterile.

17,518. When was the method of adding carbolic to the vaccine introduced: I thought an addition of carbolic had always been made to the vaccine?—I do not think it was in the case of the very early ones. I have a bottle dating from May 1897. I am sure the early ones were not carbolised.

17,519. Do you know when the method of adding carbolic was first adopted?—No, that was before I came to the laboratory. I came to the laboratory in June.

17,520. Since then, all the bottles have been carbolised?—Yes.

17,521. Do you think that it is possible the putrid bottles we have heard of may all have been sent out before that period?—I know that bottles alleged to be putrid have been sent out of the laboratory since I joined the laboratory.

17,522. How do you account for this? Do you think the carbolic can have been omitted, or that it can have evaporated?—I think the officer who tests this is an exceedingly careful worker—Dr. Paymaster—and, I do not think, in any instance, he has failed to carbolise the flask. But, of course, an accident may have occurred. As to its having evaporated afterwards, I really could not say. I should think it was possible.

17,523. You say that in certain cases, where the decanting staff found that the vaccine was contaminated, you found, when you came to test the bottles, there was no contamination?—Yes, that is so.

17,524. How comes it that the decanters were so careful in the matter of not introducing bacteria into the bottles, when they were so little careful in the matter of not introducing contaminations into the agar tube? You say they introduced contaminations into 50 per cent. of the agar tubes, and that none the less you found that they did not introduce any contaminations into the bottles; how do you think that came about?—In the one case the organisms fall on a fertile surface, in the other in an antisepticised fluid. The men whom we were obliged to take to do the decanting were men who would be laboratory boys at home, absolutely ignorant of what bacteria are or anything about them. It was hopeless at first to get them to do the work properly.

17,525. How is the vaccine standardised?—Professor Haffkine does that.

17,526. Do you know how it is done? Is there any trade secret as to how it is done?—No.

17,527. Do you know how it is done?—Yes, I know M. Haffkine judges by the amount of sediment in the fluid; he compares the amount of the sediment. *This* bottle (shaking it up and holding it up to the light) he would probably mark 10 c.c., and *this* (shaking it up and holding it up to the light) would be about 5 c.c.

17,528. Do you think it is an accurate way of standardising?—Personally, I do not.

17,529. Do you think you could get a fluid of more constant strength if you decanted off the supernatant fluid?—Yes, I think it would be possible to get a more constant fluid.

17,530. Do you know whether the supernatant fluid is or is not toxic?—I do not know. I mean to try that.

17,531. You have not compared the toxicity of the supernatant fluid with that of the sediment?—No.

17,532. When you say the microbes disappear from the blood soon after death, do you mean that in a case where you have been able to see them under a microscope the bacteria disappear from view in a few hours, or do you mean that after a lapse of hours you cannot get cultivations?—We cannot get cultivations.

17,533. But can you still see the bacteria?—You can see forms which you take to be plague, but, as a rule, you cannot get satisfactory cultivations. Of course, I have examined plague rats 16 hours after death, and got plague bacillus from them both in microscopical tests and in cultures; but, as a rule, the plague bacilli

are crowded out by putrefactive bacilli—absolutely crowded out.

17,534. Have you examined the blood in a dead rat on two successive occasions, and have you, on the first occasion, found the microbes, and on your later examination, failed to find the microbes?—No, I have not.

17,535. Do you know whether the strength of the prophylactic decreases when it is exposed to a boiling temperature?—No, I do not know that.

17,536. Have you made any experiments to determine that point?—No; and I have no experiments also with regard to doing anything to the fluid after it has been decanted.

17,537. (*The President.*) What is the reason for the selection of bottles of the shape used?—Because you can fill up the syringes more easily from them. The neck and the body of the bottle are in the same plane.

17,538. It depends upon the length of your injecting needle?—The needles which we have are all long. We can put them in about *here* (pointing to bottle) quite easily, and in pouring out the fluid you can get the whole of the fluid out.

17,539. In practice, is it found necessary to pour the whole contents into one glass?—In the rules we specially say that that is not to be done.

17,540. You can hardly empty the bottle otherwise?—I have never any difficulty in emptying the bottle.

Capt. C. J. R. Milne, I.M.S.

13 Feb. 1899.

17,541. This prophylactic fluid, apparently, consists of two substances, one liquid and one solid?—Yes.

17,542. Which is the prophylactic ingredient?—The solid.

17,543. What is the function of the liquid?—Professor Haffkine, I believe, considers that the fluid part has an effect on the case mortality—that if a person who has been inoculated gets plague the fluid portion of the prophylactic helps him through with it.

17,544. On what grounds do you say that the solid is the prophylactic?—M. Haffkine has told me so. It is not my own observation, because I have done no experiments on the point. I have simply been working under him.

17,545. Is there any special test to determine the prophylactic efficiency of any brew before distribution?—We do not test it in any way.

17,546. You judge simply by the amount of solid matter?—Yes. Of course Professor Haffkine does all that himself. I have nothing to do with that.

(Witness withdrew.)

Lieutenant J. K. Condon, I.S.C., called and examined.

Lieut J. K. Condon, I.S.C.

17,547. (*The President.*) You are Under-Secretary to the Government of Bombay?—Yes.

17,548. (*Mr. Hewett.*) You were employed, I believe, on plague duty at Bantwa, a town in a Native State in Kathiawar?—Yes.

17,549. What is the population of Bantwa?—It is calculated at 8,500. The 1891 census was 8,200 odd.

17,550. At what stage of the epidemic did you arrive at Bantwa?—I arrived about the 10th September 1898.

17,551. The epidemic was a very severe one, was it not?—Yes.

17,552. What was the total number of attacks?—944.

17,553. That represents about 11 per cent. of the total population of the town?—A little more.

17,554. Can you give us an estimate of the number of people who had left the town?—I think about 500 or 600. It is calculated there were 7,500 people there when I was there.

17,555. What number of deaths occurred in the epidemic?—602.

17,556. When you got to Bantwa in the month of September what measures were in operation?—It was raining very hard, and practically there were no measures taken beyond the erection of hospitals and some small camps.

17,557. On what date were measures to clear the people out of Bantwa undertaken?—Between the 25th and 30th September.

17,558. What proportion of the total attacks and deaths had taken place up to the date when you got the people out?—A certain number of people had been turned out by my predecessors in August, but unfortunately a storm took place and they all went back again to the town. That settled the question. 772 attacks and 467 deaths took place before the people went out the second time.

17,559. When did the storm take place?—On the 12th September. There were about 2,000 people segregated from the time of the end of August.

17,560. Did those segregated by the end of August include all the people among whom the plague broke out, or was there also plague among the other people in the town?—No.

17,561. Were the whole of the residents of the infected portions of the town in camp or not?—No, because the infection was all over the town.

17,562. Was the worst part of the epidemic over before September 16th, the date when you were able to begin effective measures?—Yes, apparently; or at least it had reached its climax.

17,563. What was the number of attacks respectively before you took effective measures for getting the people out of the town, and after you had done so?—467 deaths took place before evacuation, but I should like to explain that evacuation, at least as I understand it, never took place in Bantwa at all. There is absolutely no reason, so far as I can see, which anyone can give for the subsidence of the plague there.

17,564. Except that the disease itself began to die out?—Yes. There were never more than 2,000 people—one quarter of the town—evacuated. The decline in the disease might have been due to the weather, because we had a spell of very fine weather immediately after the storm.

17,565. Did anything come under your observation as to the communication of the plague by rats in the town of Bantwa?—In a great many of the houses which were badly infected dead rats were found. In one house in which 16 cases took place we found a lot of rats.

17,566. Has your experience led you to the conclusion that the rats were moving from house to house and carrying the infection in that way?—Yes, for this reason: in the town when plague began the houses where rats were caught and killed were, of course, disinfected, but rats afterwards came to where we were living, and, in fact, appeared in our own stables. On finding them we turned the servants out and disinfected the rooms. None of the servants were attacked.

17,567. Did you observe distinctly the migration of the rats?—I do not think I could make that statement, but that was the general belief. I think they were driven from one place to another, although, of course, I did not see them. It was only a distance of 1½ miles or 2 miles.

17,568. Did any other place in the neighbourhood of Bantwa become infected?—All the surrounding villages—four or five of them within a radius of 3 or 4 miles.

17,569. Were you able to trace the cause of the infection of any of those villages?—Not with certainty.

17,570. Did you turn the people out?—Yes; in the villages every person was turned out.

17,571. Did the epidemic last long in any one of those villages?—I think Nakra lasted within a month as long as Bantwa itself. It was going on after Bantwa.

17,572. Did it begin at the same time?—No, five or six weeks later. I do not think there is any doubt that Nakra was infected from Bantwa.

17,573. When you got the people out of these villages did you prevent any communication between them and the infected site?—As far as it was possible, but I could not rely upon the Police there. They were all State Police and unreliable. In fact, in some cases people did get back again, and the Police were punished in consequence.

17,574. So that you have no security that the segregation of the people was at all effective?—In one village it certainly was effective, and that is Kambhla.

Lieut. J. K. Condon, I.S.C.

13 Feb. 1899.

17,575. How long did it take to suppress the disease in that village?—The epidemic in Kambhla began at the commencement of October and it stopped in the first week in November. There were 23 cases with 21 deaths.

17,576. Why should it have taken so long to suppress the outbreak there if segregation was effective?—Because the people kept going back from the camp to Bantwa.

17,577. Bantwa was also infected at the time?—Yes.

17,578. Then the segregation was not effective in preventing the people who were segregated from going to an infected site?—No, it was not. What I meant was they did not go back to Kambhla.

17,579. But they went to other infected places?—Yes; there is no doubt they went to Bantwa and they might have been to Nakra.

17,580. (*Dr. Ruffer.*) Can you tell me what was the shortest duration of a case of plague that you observed personally?—The shortest case I personally observed was that of a man at work in the fields about 6 o'clock in the evening; he was cutting the crops. I happened to be riding back from Bantwa at night, and they said that this man was taken ill. I saw him between 6.30 and 7 p.m. When I went back the next morning I found he had died about 9 o'clock. That would be about 14 hours. This was the shortest case that came under my own observation. It is possible that many of the cases found dead were more rapidly fatal.

17,581. Did you notice dumbness as one of the sequelæ of plague?—Yes, dumbness came on when the people had had plague about a day or two in hospital. You could not get them to answer, they used to shake their heads.

17,582. Did you find that people who recovered became more or less idiotic?—We had four or five cases of lunacy after plague.

17,583. How long did it last?—I do not know.

17,584. Did they recover?—I cannot say.

17,585. You mention in your précis that loss of sight followed careless handling of the bubonic discharge in some four or five cases; do you mean the patients got ulceration of the cornea?—They lost their sight altogether; the eyesight went.

17,586. Did they get disease of the eye?—The eyes became quite colourless; the blue became a whitish blue. In some cases the eye was lost altogether.

17,587. Did the eye suppurate?—It became very much inflamed and painful. To the best of my recollection there was suppuration and a discharge from it.

17,588. Why do you think it followed careless handling of the bubonic discharge?—That is the only reason we could assign to it. We would open a man's bubo and then he would have to squeeze it himself and wipe it. Very often he would squeeze it carelessly with his hand and then rub his eye or his face or something of that sort, and it was generally after that that it came on. I think there were some six cases of loss of sight altogether.

17,589. I understand you saw one house where there were 16 cases, and some occurred after it had been disinfected?—Yes, that was a most extraordinary case.

17,590. Can you give us the details of that?—I regret I cannot, because cases occurred before I went there—about eight or ten of them. The house was pointed out to me as the worst plague spot in the city. It was in the very centre of the city.

17,591. At that time the plague was all over the city?—Yes.

17,592. So that these people may have infected themselves somewhere else?—That is possible, but all the cases occurred in the house.

17,593. (*Mr. Cumine.*) Has there been any case in Bantwa this year?—Not this year.

17,594. No case since it ceased last year?—Since it ceased on the 5th November there has been no case reported.

17,595. (*The President.*) What kind of house was it in which these 16 cases occurred?—It was a collection of houses; a house with rooms added to it all over the place. It was not strictly a group, but it was built up of several houses. It was in a compound by itself surrounded by a wall from 5½ to 6 feet high.

17,596. What do you mean by dumbness, that the patients were speechless?—Most of them were not absolutely speechless, but some of them were. The majority could make sounds, but they were not intelligible; they could not speak distinctly.

17,597. Did the voice go?—The articulation seemed to go.

17,598. (*Dr. Ruffer.*) Is there any medical man in Bantwa?—On my arrival I found the plague work entirely in the hands of State Hospital Assistants.

17,599. During the whole of the epidemic?—Khan Saheb Fazl Ahmed arrived shortly (about ten days) after I did, and did good work.

17,600. Was there any European Medical Officer?—No. I believe Major Burke, Civil Surgeon at Rajkot, visited the Plague Hospitals in August, but beyond this none of the patients were even seen by a European Medical Officer.

(Witness withdrew.)

Mr. S. R. Arthur, I.C.S., called and examined.

Mr. S. R. Arthur, I.C.S.

17,601. (*The President.*) You are Collector of Kolaba?—Yes.

17,602. (*Mr. Cumine.*) During the fair weather of 1896-7, you were in the Satara Collectorate?—Yes.

17,603. I think some parts of Satara are very much over-populated, and a great many of the people come to Bombay to work as porters, and so forth?—Yes.

17,604. When the exodus from Bombay occurred in 1896-7, did a number of those people go back to their own country?—Yes; and the result was that some two or three villages became infected. I found a number of deaths ascribed to ordinary fever, and afterwards I thought that probably a very large number of those were due to plague, because I noticed they occurred among people who had returned from Bombay. At the time nobody knew much about bubonic plague, and I did not go into it till rather later; but I noticed that several cases occurred together. One man came from Bombay, and died of fever; and just after that, within a fortnight or so, there were several cases of fever in the village, all of which proved fatal very quickly.

17,605. Was there one village which seemed to escape infection in a wonderful manner in spite of a lot of people pouring into it?—Yes, Wai.

17,606. Where did the refugees come from?—A tremendous number of people came from Poona every day.

17,607. And yet that village never got infected?—That is so.

17,608. In March, 1898, you went as Collector to Kolaba?—Yes.

17,609. In the Kolaba District, I believe, there were three centres of plague?—Yes; one, Revdanda and the neighbouring villages; secondly, Karanja and neighbouring villages; and, thirdly, the town of Alibag itself. Panvel was also infected, but the plague stopped just when I arrived in the district.

17,610. With regard to Revdanda and its villages, you have no personal knowledge?—Not very much. I went down there, but there was an officer on special plague duty there.

17,611. With regard to Karanja and its neighbouring hamlets, what was the important point which struck you most?—The course of the plague at Karanja and the neighbouring hamlets in the Uran petha of the Panvel taluka demonstrates no less clearly than Alibag the advantages of evacuation. I went there first about the 23rd March 1898. Four or five cases were then occurring daily. The late Mr. Brooke, my Assistant, had already ordered evacuation just before my arrival, and the order was complied with, but the people were concealing cases, and we had some difficulty in impressing on them the importance of giving immediate information of cases and deaths. Eventually the people promised to comply, and did so loyally. Panches

were appointed, the hamlets were divided into sections, and one Head man held himself responsible for each section, and gave information of cases and deaths immediately on their occurrence, on which the huts in which cases had occurred were burnt down and the occupants segregated. The result was immediately apparent. The number of cases dropped from 23 and 24 in the weeks ending 19th and 26th March respectively, to eight in the week ending 2nd April, three in the week ending 9th, and none afterwards, except a sporadic case here and there. What chiefly struck me was how very quickly it stopped when we got the people out and got the cases immediately reported.

17,612. But the way in which the people found out cases themselves and reported and isolated them was also striking, was it not?—Yes; we had no difficulty with them at all directly they understood what we wanted, and when they knew that we were not going to do anything with them except to put them in different huts.

17,613. With regard to the town of Alibag itself, I think you arrived there just at the beginning of the second epidemic?—Yes.

17,614. The point which you wish to emphasise is, I understand, the number of attacks in the season of 1897-98 as compared with the number of attacks in 1896-97, and the cause of the difference?—Yes. The history of the plague in Alibag is most instructive as showing the advantage of early evacuation. In the first half of the year 1897 there were 266 cases and 244 deaths. This was the first attack. The plague came on the people as a disease of which they had no experience; they did not at that time appreciate the advantage of evacuation, and were slow to resort to it. From July 1897 to March 1898, Alibag remained free, with the exception of one case in October and three in January. When I took over charge of the district on 19th March 1898, the second epidemic had just commenced; seven cases had occurred, and my predecessor, Mr. Quin, had ordered the evacuation of the infected quarter. I continued his policy, and on cases occurring, immediately caused the evacuation of the affected parts. Nor did I find any difficulty in inducing the people to obey the order. Taught by the bitter experience of the previous year they were only too ready to leave on the first appearance of the plague. The results are apparent in the returns. The first three weeks showed 17 cases, the following four weeks showed nine, and the attack then ceased, May, June, and July each producing one sporadic case only.

17,615. From July 1897 to March 1898 Alibag remained free?—Yes, with the exception of one case in October and three in January.

17,616. Do you know whether the outbreak which had just begun in March 1898 was due to an importation of infection about that time? Could you trace importation of infection in February or the beginning of March?—I am afraid I cannot say, because it began some days before I joined there. I did not look into the matter myself. I can speak with regard to the latter epidemic into which I did inquire myself, but I was not in the district when these first cases occurred, and I am afraid I cannot say whether they were imported or not.

17,617. When did the second epidemic in Alibag, which was going on when you arrived there, end?—In epidemic form on 29th April. There were subsequently only three sporadic cases in May, June, and July, one in each month.

17,618. Has plague appeared in Alibag again this fair season?—Yes, it is going on now.

17,619. Can you trace its re-appearance in Alibag to any fresh infection imported?—No, I think not. It started with a great mortality among rats long before cases were reported to me. For about a fortnight or three weeks before there was a great mortality among the rats.

17,620. Have there been any imported cases?—I think not. I think it is a pure recrudescence in the place itself.

17,621. Did it reappear in the part of the town where the last epidemic died out, or among the people among whom the last epidemic remained the longest?—No. This year it is more among the Brahmans, whereas last year it was chiefly among the Kolis, who live quite in a separate quarter.

17,622. What disinfectant had you used during the epidemic which was going on when you arrived in Alibag?—We have used perchloride of mercury all through; we have also, of course, unroofed the houses.

17,623. Did you disinfect every house or only the houses where you thought cases had occurred?—We disinfected the houses in which cases had occurred and also the surrounding houses. I think a good part of the town was probably disinfected.

17,624. But some of the houses were left undisinfected?—Of course Koli Wada received the most attention, where cases were occurring last year. Nearly all the Koli Wada was unroofed and disinfected, and as yet we have had no cases occurring there, although rats have died.

17,625. There were a certain number of houses which were left undisinfected?—I cannot say that the whole of the town was disinfected, but the greater part of it was.

17,626. Who was in charge of the disinfecting operations in Alibag town?—The Deputy Collector, and Assistant Surgeon Pereira.

17,627. As regards the mortality since April to this present recrudescence you have been watching it carefully, I suppose?—Yes.

17,628. Have you noticed whether the mortality in the interval has been heavy among children under five?—I could not say.

17,629. Have you noticed whether the deaths have been occurring in clusters, or more than one in the same house?—Do you mean during the time there has not been any plague?

17,630. Yes?—No, I do not think so. I have noticed carefully the mortality from fever, but nothing else particularly. If several cases of fever had occurred in one house, or in a cluster of houses, we should have noticed that at once, and probably ascribed it to plague.

17,631. You have been looking not merely to the number of deaths but also to the places where they occurred?—That is so. There are general orders in the district. If in one house or in one neighbourhood a large number of fever cases occur we immediately get reports of them.

17,632. Are you aware whether there has been any outbreak of mumps in Alibag during the rains?—Not that I know of.

17,633. I think that in Mora Bandar in the hot weather of 1897 about 393 persons were inoculated?—Yes.

17,634. Were you there at the time?—No, I was not.

17,635. Have you any personal knowledge of what has happened to those people, how many of them are dead and how many are alive?—I have no personal knowledge, but I think I could say generally that Mora has not been affected with plague since. Of course that is astonishing, because Mora is a bandar exactly opposite Bombay, which is very much used, and it is only four miles by road from Karanja, which was very heavily attacked. I did not go to the district till 1898, but from the hot weather of 1897 there has been no plague at Mora, although it is a place which has considerable traffic with Bombay.

17,636. I think that Alibag and Panvel, and also two villages named Thal and Naogaon, are infected at present?—Yes, and Cheul has also been infected since I wrote my précis of evidence.

17,637. How many villages are now infected?—Three. Of course, I am not counting sporadic cases. We are perpetually getting single cases imported from Bombay and other places; they are removed at once, the house is disinfected, and, generally, no further cases occur if the measures are taken promptly.

17,638. You have three villages now with indigenous plague in them?—Yes.

17,639. Does any one of them adjoin a village which was infected last year?—Panvel has been infected each year. I have no villages infected now except Cheul.

17,640. Does that village adjoin a village which was infected last year?—Cheul was infected last year, and so was Revdanda.

17,641. How is plague carried from village to village?—Is there any case known of rats being actually seen

Mr. S. R. Arthur, I.C.S.

13 Feb. 1899.

migrating from one village to another?—No, I do not know of that.

17,642. Do you think it would appear to be carried by human beings?—Yes, but I think it is also very likely carried by rats.

17,643. But you have never seen any rats actually going from one place to another?—We know it is carried from one part of a town to another by rats.

17,644. How do you know that?—I say this because mortality amongst rats has been observed first in one part and then in another; then, within a fortnight or three weeks, one sees plague among human beings. That is the history of plague in Alibag this year.

17,645. Could you be confident that there has not been first a concealed case of plague among human beings in that part where rats have been dying?—I do not think that there has.

17,646. Do you believe in disinfection by perchloride of mercury?—I believe the sun is by far the best disinfectant, because I think it is very difficult to disinfect thoroughly with perchloride of mercury.

17,647. Is it not difficult for the sun's rays to operate in dark houses?—We unroofed almost entirely. I do not believe in taking off a narrow strip, because, of course, the sun reaches very little.

17,648. It would not be feasible to unroof during the monsoon?—No.

17,649. Then you cannot rely on disinfection by the sun during that time?—No.

17,650. Do not you think that the monsoon is a favourable season for plague outbreaks in this part of the country?—As far as my experience goes it has stopped almost entirely before the monsoon. I do not think that in Alibag we had any cases last year, or in Panvel. Each of the infected towns in Kolaba was infected in the cold weather, and the cases dropped off as the hot weather came on. In the rains there were no cases at all.

17,651. There was a great deal of plague in the Satara district in the rainy season, I think?—Yes, in Karad.

17,652. Does not that modify your statement that it does not occur during the rains?—I was speaking with regard to my own experience, but I was also in Satara. The only town in which it occurred last year during the rains was Karad.

17,653. During the rains would you not have to resort to some other method of disinfection?—Yes. I have not, myself, taken plague measures during the rains anywhere; but, of course, I should try to evacuate houses as far as I could, and introduce inoculation.

17,654. But you would have to let the people back into their houses at some time?—Yes.

17,655. Do you think that it would be impossible to effectually disinfect the houses with perchloride of mercury?—I should think that disinfection with perchloride of mercury should be done in the rains; I only said that I thought sun disinfection was the best which one could get. We have a large staff of disinfectors, but I think it is very difficult to get work done very thoroughly so that every atom of space is covered.

17,656. The work involves a lot of supervision?—Yes, and we have not sufficient means of supervision.

17,657. (*Dr. Ruffer.*) Why do you think the sun is the best disinfectant?—From experience it seems to me that directly one unroofs a house that is quite enough to stop everything. We always unroof the houses.

17,658. But you disinfect the houses as well, do not you?—Yes, we generally do, but we unroof a great deal more than we disinfect.

17,659. I want to know on what evidence you base the statement that the sun is the best disinfectant?—I am speaking, of course, from what I have learned from the doctors.

17,660. You have no facts of your own?—No, I have not.

17,661. (*The President.*) Have you had cases in which, having unroofed the houses and allowed the people to return, plague has occurred again in the same house, independently of a fresh importation?—My experience of plague is confined to the hot and the cold weather. When we once evacuate a house, the people themselves do not wish to return till the rains, so that a house remains empty for three or four months generally.

17,662. But they do return at the end of two or three months?—Yes.

17,663. Assuming they return, has plague ever occurred in houses which have been opened up, apart altogether from fresh importations?—Not that I know of.

17,664. It has, therefore, proved practically effective in your experience?—Yes, I think so.

17,665. Do these cases which you speak of include cases in which the houses have not been otherwise disinfected?—No, it does not, because every house in which the plague cases have occurred is otherwise disinfected.

17,666. Your opinion seems to be that evacuation is a very effective measure?—I think it is the most effective of all except inoculation.

17,667. In many cases you have been able to stop plague which has been imported by at once segregating the infected persons?—Yes.

17,668. In order that that measure should be effective you must obtain early information?—That is the most important thing of all.

17,669. What is your organisation for obtaining this early information?—We do it through the district staff. There are general orders in the district about plague. When cases of fever occur in a house or in a cluster of houses in a village one after another, they have to be immediately reported.

17,670. Who reports them?—The village officials report to the Mamlatdar, who reports to me direct. Probably I should know at least within two days.

17,671. How does the village officer obtain the information?—In the ordinary course he has to enter births and deaths in the register immediately on their occurrence and has to keep himself informed for the purpose.

17,672. Before the plague patient dies he may spread the infection widely in a village or town: have you any means by which you can determine that there is a case of plague before death has taken place?—No, I am afraid we could not tell that: I do not think we could ever know until one or two cases had occurred.

(Witness withdrew.)

Dr T. Blaney.

Dr. T. BLANEY called and examined.

17,673. (*The President.*) You are a practitioner in Bombay?—Yes.

17,674. You have been here for a long time?—I have been practising here for half a century, a little more perhaps.

17,675. You have taken much interest in the affairs of the city?—Yes. I have occupied every position which a non-official in a city such as this can occupy.

17,676. You have paid much attention to the epidemics of plague?—I have followed them; I have put aside everything else to pay attention to them.

17,677. In the first place, what is your opinion with regard to the influence of rats in the diffusion of plague or to the introduction of plague into any part of the town?—I submitted some remarks on that point in a paper which I sent to the Plague Commissioner, Bombay, according to his own request. I said in this:—

"One more item of evidence may be offered in connexion with the spread of plague by rats. This evidence is derived from experience in our wet-docks. The docks were filled with ships during both our plague epidemics. During these epidemics the usual interchange of rats between the docks and the shore continued as formerly, and that the interchange should be considerable and not rare or occasional may be inferred from the fact that the great rat infested granaries of the city are situate immediately in front of the docks and at no great distance from them. When the question is asked: 'How were the ships in 'the docks affected by the rats on board?' the

reply is, 'The rats carried no infection to the crews of these ships.' As far as I know, if infection reached the ships at all, that infection was brought there by persons infected in the town, and was not carried on board by rats. It is indeed a remarkable fact that while plague raged all over the Mandvi district, the crews of the ships in the docks remained uninfected during both epidemics, while the distance between the shore residents and the ships was well within striking distance of the infection. It may be mentioned that the crews of the ships in the docks were largely composed of Muhammadans and Portuguese, classes very susceptible to plague infection, and not wholly of Europeans or immune persons. As rats do not desert houses during a plague epidemic on account of the disease, they do not carry the plague from house to house or from district to district. The only influence they exercise on plague may come from their power to increase or intensify the infection existing in the houses by their excretions during the period of infection, or by their bodies after death. The proofs of this power of infection by rats, or the power of rats to carry and spread infection, are yet wanting. It is known, however, that plague may continue in active evidence as well without rats as with them. Rats are not an essential factor in a plague epidemic. Hence when we hear that somebody has killed a thousand or ten thousand rats, the reduction is no proof that plague has been diminished to that extent."

17,678. Will you favour the Commission with your opinion as to what influence rats have in disseminating plague?—Very little, I think. Where rats leave their excretions in the houses, on the bedding, clothes, and so on, while they are infected, they may possibly disseminate the plague in houses, and also when they die on the premises and remain there they are a great source of infection. That I have seen over and over again.

17,679. But they do not diffuse it widely?—No. The crucial point about that is the evidence with regard to the docks, which I have already given.

17,680. What opinions have you formed as to the conditions which influence the rate of plague mortality?—There are different degrees of susceptibility in the classes which are constantly maintained.

17,681. Race susceptibilities?—Yes, and diet susceptibilities, or the susceptibility of habits. I have worked out these figures again and again, but I went through one complete epidemic from the beginning of July and ending the following July. I have worked it out in 20 different ways in 20 different communities in different parts of Bombay, and the figures are almost identical. The table which I have before me contains the official record of plague deaths during the whole period of the duration of the second epidemic, namely, from the week ending the 6th July, 1897, to the 28th June, 1898. With regard to the Jains, a particular caste here who are jewellers, grain dealers, and generally wealthy, the great trading class, the rate of mortality from plague is 38·05. I believe some doubt has been thrown upon the correctness of this rate by the late Plague Committee, Sir James Campbell's Committee, but I have been in correspondence with people in America and different parts of Europe, savants, and also people who are interested in the trade with this city, and I have been able to dissipate the errors which appear to me to be in the report of that Committee.* The rate of mortality among the Jains, surprisingly large as it is, is real, and it is due to the fact that animal life is sacred among the Jains. They will not sweep their staircases or sweep their sleeping rooms out, or their cooking room very often, lest they should destroy some animal life, so scrupulous are they. Only half of the vegetables which are used by the natives in Bombay are eaten by these people, because animal life has been found in them. There are sundry other social peculiarities about them which render their sleeping places and cooking places particularly susceptible to the attraction and preservation of the infection.

17,682. Are these places very dirty?—Not in that sense. They are wealthy people, and their places look comparatively clean. But if there is such a thing as infection which is not apparent to the eye which might be got rid of by brooms and disinfectants and throwing open windows and allowing the light and air to enter and so on, that infection would remain so far as the Jains are concerned. I have seen numbers attacked in the same house again and again where, ordinarily speaking, from their social position, wealth, and so on, they ought not to be attacked. That is the explanation with regard to the Jains. There are those religious peculiarities in them which keep the death-rate at that great height, and it will always remain so.

17,683. That is the plague death-rate?—Yes. I have gone over the statistics for about 25 years with the same community so as to verify or shake the opinion which I have formed about their mortality, and their mortality is in excess of all the other Hindu populations, apart from plague in ordinary years.

17,684. Are their habitations otherwise rather better than the average?—They are. The next on the list are the Bhatias, which is also a very wealthy caste. They hold the whole of the grain trade of Bombay, which means millions, and also the ghee trade, to a great extent, the cloth trade, and many other trades. Their death-rate is 26·48. The difference between the Bhatia death-rate and the Jain death-rate is this, that the population upon which it is estimated is much smaller, the Jains being four times as large as the Bhatias, 25,000 to 6,000. Therefore the figures are, of course, more reliable for the Jains. The Bhatias are a small class, but their mortality must be very large, because, with all their wealth, they ran away from Bombay until there was not one-third of the population of Bhatias left in Bombay, which ordinarily exists here, and still their death-rate for the second epidemic was 26·48, and it was the same the first year. The death-rate amongst them must have been very heavy. I will take next two together, because they are Hindus, one low caste and the other high caste. The difference between the two is only a matter of degree of poverty. There is not much difference between them. Formerly the low-caste Hindus used to eat all kinds of offal and bad stuff, but they do not do it now. They are more well-to-do, being in good employment, and there is no necessity for them to it. The death-rate in the higher caste is 21 per 1,000 as against 24 in the low-caste Hindus. I think those ought to be taken together, giving an average of 22½. The next are the Brahmans, which is an important caste. They are supposed to be of cleanly habits, and they belong to the intellectual classes. They are not in great poverty, and where they are in poverty they prefer it, being professional beggars and living well by their trade. Their death-rate is 20 per 1,000. The next is the native Christian, which is a poorer population. They are what we may call Hindus Christianised. Practically in lives, habits, and hopes they are Hindus. Their death-rate is 15. That shows that, being Christianised, they have improved somewhat, because their death-rate is lower than that of all the classes in the Hindus. When they are Christianised they eat everything. They go in for pork and turkey, roast beef, and so on.

17,685. They do not live in better houses?—No, they are poor. The feeling of the other Hindus is against them. It is hard work for a Hindu to be a Christian in his native country. They are not very well treated, because they are Christians, but their diet is certainly superior, and I think that accounts, to a considerable extent, for their lower mortality with regard to plague. I believe that the native Christian returns are fairly correct. Next come the Parsees, 9·42 per 1,000. They are, of course, a clean-feeding and well-fed people and intelligent, and they have rather a small mortality. The Muhammadans come next, 9·44, which is practically the same. The Muhammadans and Parsees stand upon the same level; their diet is very similar, the only difference being that the Parsees never eat beef, and the Muhammadans always do when they can get it. Then come the Eurasians with a death-rate of 7·30 per 1,000. That is rather high. I do not know why it should be so, because their houses are fairly good and their diet is exactly like ours; there is no difference. Still, they do get attacked in very much larger proportion than the pure Europeans, and when they are attacked they die very heavily. Then come the Jews, which is 5·7. They are a very clean-living population, but their numbers are very small. There are only 4,000 in the whole of Bombay. Still, I think this is a fairly correct representation. Lastly, the Europeans have a mortality of 1·06 per 1,000; they are almost immune.

17,686. Do you think it is entirely a question of race in the case of Europeans?—Habit, diet, housing, and

* Report of the Bombay Plague Committee on the plague in Bombay from the 1st July 1897 to the 30th April 1898, by Sir James Campbell.

Dr. T. Blaney.
13 Feb. 1899.

even clothing, I think, are all represented. I think, if this table were constructed 50 times over in 50 epidemics the figures will turn out the same. I have tried it in the last three epidemics, and it is wonderful how exactly they do work out.

17,687. To what extent do you think that poverty influences the mortality?—Exactly to the extent that it affects the mortality in ordinary years, not more. That would be, perhaps, in a ratio of 5 to 10.

17,688. To what extent do you think the housing of the people affects the mortality?—There the Commission has hit the great point. I think Lord Sandhurst's scheme is almost an answer to this; overcrowding is *the* great question in Bombay with regard to plague, with reference to the extent, the severity and preservation of infection in houses. I think this is the great blot on the Bombay system. If the Commission will spare me five minutes just to show them how 400,000 out of our 800,000 live, perhaps it will explain it in a nut-shell. The system is to get house accommodation on the cheapest terms. A single man has 10 rupees a month as an income. If he is a single man he goes to a man who takes in borders and lodgers, and says to him, "Here are 2 rupees 8 annas a month for you, "and you must feed me and give me a place to lie "down in." That is all he asks for; there is no furniture of any kind. The man says, "No, but I will "do it for 3 rupees." That leaves him 7 rupees of his salary untouched. The 3 rupees would include all his food and his house rent. It would not include his clothing or his betel-nut. This is the extent to which he pays for his actual subsistence, and more than that he will not pay. Our Municipality, for years past, knowing deliberately that the great mortality in excess of what it ought to be was caused by this overcrowding, has absolutely made laws—and never attempted to carry them out. I have roared myself hoarse at the Municipal Board meetings again and again for the last 25 years on this subject, and at last Lord Sandhurst's scheme, I suppose, is going to show you the difficulty can be got over. I have given up public life and public work, but I was pressed to go upon this new Trust; they placed me there as a member, and I hope that this overcrowding question will be properly looked into, even if we are going to spend a million, 2 millions, or 5 millions. The dispute at present between Lord Sandhurst and myself is this: he says he will do it for 5 millions, and I say he will not do it under 10 millions. The money would only be rightly spent when the overcrowding is abated. In a simple epidemic of any kind, be it our usual seasonal fevers, measles, or what not, you can go along the verandas and see the people lying there—all attacked in the same way—because they live too closely to one another, and breathe into one another's faces. I only wish to emphasize as much as I possibly can that the overcrowding has had a great deal to do with the intensity of the epidemic and the greatness of it.

17,689. What evidence have you that overcrowding has had an influence upon the incidence or mortality of plague?—I can only say in a general way that I believe it has kept it up and intensified it.

17,690. You have no figures?—No, it is very difficult to get them.

17,691. Can you tell us if plague has occurred chiefly in insanitary houses or insanitary districts?—Yes. I think it may be generally answered so, although, if you ask me if I have seen a great number of very good houses in which plague has been very heavy, I should say yes. I saw that in Mandvi. But as a rule, I think it has occurred in insanitary houses, because when you come to the outlying districts which contain the poorest population and the worst houses there we see the plague has the greatest intensity.

17,692. By insanitary dwellings or insanitary conditions, what do you include besides overcrowding?—Darkness, dampness, and want of ventilation. They are rookeries in lots of cases. In many of the outlying districts a man can hardly stand upright in his house. They are not fit for human habitation at all.

17,693. Do you believe the plague has been influenced by the mental state of the people?—At first it was so.

17,694. On what do you form that belief?—For three years I have had no income in December, January, and February. It was said, and there is some truth in it, that I have the largest medical practice of any man in Bombay, probably due to my very long acquaintance with the natives, and in December, January, and February, they will not come to me, nor will they send to me for fear of the plague officials carrying them off.

17,695. Are you a plague official?—No, but the plague officials follow me. The day before yesterday a wealthy gentleman sent for me. He said: "I was "going away to my country and only wanted you to "see that I was in good health before going away, "but immediately after you had gone two or three "plague officials came here and said: 'Dr. Blaney "'was here; what is the matter; show me your wife; "'show me your servant.'"

17,696. Do you think this state of anxiety has actually affected the mortality?—It did during the first year, but it is not doing so now. The people are brave now.

17,697. Have you been able to measure the effect? Can you state it in any definite form?—Not in any definite form. I was the Registrar of the cholera deaths in Bombay 50 years ago for the Government, and I used to collect often 100 death certificates in a day from cholera. The people took it as being quite a matter of course—it might be catarrh, or diarrhœa, or anything—nobody bothered about it. They took it very philosophically, if that word can be used in such a connection. That is the feeling now. There is nobody who has any fear now. I have, in the first year, seen insanity, following the fear of the measures, again and again.

17,698. How has the mental condition influenced the mortality of plague to your knowledge?—That would require a long time to answer. The statement made in my précis refers to the first year when the people were disturbed with the operations. It was that fear which influenced the mortality. I have seen over and over again people just lying down and giving up, where, under other circumstances, if there had been no fear, they would have, perhaps, striven against it and taken remedies, and done things which they would not do under that fear.

17,699. Have you any knowledge as to how long plague if uninterfered with would last in a city or district into which it had been introduced?—I think it has its cycle of years, but that, of course, is only supposition.

17,700. You have had some experience of the use of curative serums?—A little. In my practice I have estimated that I have done about 24 inoculations, with Yersin's serum and Lustig's serum. I have used none of that which they are now making at Parel at the present time. I selected all the cases which I inoculated, and, therefore, I did not think I could put those cases forward.

17,701. On what grounds did you select them?—As being immediately attacked and as being in perfectly good health before they were attacked.

17,702. You got them in the early stage?—Yes, and I got a good result. The result was that in several of the cases there was almost immediately subsidence of the fever and of the bubo also.

17,703. How many cases had you?—About two dozen. I remember one case, where I stopped with the girl about 70 minutes after I injected her with Yersin's serum, and in that time the temperature went down from 105 to normal. She sat up in bed—she was a fine, young, strapping girl—and said, "Come here, Father, I want some breakfast." She sat down and had a very good breakfast. She was taken away to the hospital and treated there, but she had no further bad symptoms.

17,704. How many of the 24 cases recovered?—About 48 per cent.; nearly half. I did not keep an exact account because I did not think the cases were fair to put before the profession as evidence of the value of the curative serum.

17,705. They appeared to be fair as showing what the serum is capable of doing when the cases were got in the early stage?—Yes, I think so.

17,706. Besides reducing the case mortality, serum treatment had an effect on the course of the symptoms?—Yes, in a few cases.

17,707. What dose did you use?—20 c.c. I think 10 c.c. was given at a time and repeated some times three or four times. I remember one case in which, in consultation with Yersin himself, I gave six injections within 24 hours.

17,708. Did the case recover?—It was a case of pneumonic plague; we did not expect it to recover.

17,709. What do you think is the most efficient measure to adopt to check plague when epidemic?—The best thing is to run away from it.

17,710. Run away from what?—From the germs, from the locality. We saw segregation going on here for a whole year, and saw the people carried out of their houses but with no reduction of the disease.

17,711. In so far as general measures are concerned, which are, in your opinion, the most effective for controlling or preventing an epidemic, apart from removing a patient?—Cleanliness and keeping in the open air as much as possible. I have always advocated that the labouring population of Bombay should sleep outside the houses, whether it rains or not. If they go into their rooms their feet and heads are together, and the whole temperature is vitiated, and even supposing there was no epidemic, they incur every possible risk because of the overcrowding in sleeping rooms. We find that those people who sleep outside the houses are very rarely attacked—those who work out in the docks during the day and keep out in the air at night also, and only spend enough time in their rooms to take their food.

17,712. What do you think are the most important measures for protecting a town or district from plague?—I think you should get the people in the open places as quickly as possible, and encourage them by every possible means to go there. The houses themselves should be well ventilated, and as much sunlight let in as possible, and there should be daily scrubbing and scouring. The main thing is cleanliness, which is not observed in an oriental city at all under the best of circumstances.

17,713. (*Mr. Hewett.*) Has the proportion of deaths to the number of persons attacked been different in the different epidemics?—I am trying to get that question worked out now at our hospitals. I shall not be able to give a complete answer till June or the end of May. There seems to be an opinion abroad that in this third epidemic the cases die in the hospital very quickly, within 24 hours, very much more than they used to do in the first or second epidemics. From my casual observations in the visits I make to the hospitals occasionally it appears so. I see during the last week or two patients are living longer. In the first and second epidemics there would be many patients who lived to the fifth, sixth, seventh or eighth day, whereas at the beginning of the third epidemic in December last they were all dying in a day. Dr. Choksy told me that in they the month of December, in his hospital, it was the same thing, but it is not so now; it is undergoing a change.

17,714. Do you think that the proportion of persons attacked who died in the second epidemic was greater than the proportion of those attacked who died in the first epidemic?—The statistics are not exact. There has been no trouble taken at the burial and burning grounds with regard to verifying the cause of death, but the figures, such as they are, are equal in both years and in all classes and in the different districts, so that no answer can be given to that question. I believe in the two first epidemics it was as nearly as possible equal, but the Commission must remember that at least 400,000 people left the city in the first epidemic, and there was no such exodus in the second epidemic. This year the mortality is decidedly less up to the present.

17,715. Do you think that there has been any great difference in the number of cases which have escaped detection in each of the three epidemics?—No.

17,716. If the mental attitude of the people was so much disturbed in the first epidemic, why did not a larger number of the attacked die than in the other two epidemics?—I believe a much larger proportion of them died, as you will find if you reduce the population from 800,000 to 400,000 and work it out in that way.

17,717. You think there were more attacks by reason of the mental attitude?—No, that is not the statement. The statement is that they were badly affected by their mental attitude.

17,718. I understood you to say that a larger proportion of those attacked by the plague in the first epidemic did not die than in the second and third epidemics?—No, I have not said that.

17,719. Did not you say that you thought the proportion of deaths to attacks was much the same in the three epidemics?—Yes.

17,720. Is not that the same question as I asked you?—No; that is where the difference in population comes in. If correction is allowed for that, then the statement is correct enough.

17,721. The question of population does not seem to come in there at all. I understood you to say that the mental attitude of the people caused the disease to be more fatal among those attacked?—No; that requires a very much longer explanation than two lines, because it requires knowledge of the actualities of the case in the matter of segregation. I was at the Arthur Road Hospital one day when a cart came up with 11 bodies in it, nine of which were dead. That explained the mental attitude a good deal. But I think it is too large a question to be epitomised into two lines.

17,722. What is your experience as to the conveyance of infection from one person to another?—It is very little.

17,723. Why do you say it is very little?—Because we do not find it.

17,724. How do you consider that the disease proceeds from one person to another?—I think I ought to have been attacked 50 times by now, but I have had the sputum in the eyes and down my throat and in my ears and everywhere about me.

17,725. Can you explain how the plague extends if neither the rats nor the people carry it?—The household goods do it; everything which is removed from an infected house will carry it.

17,726. I understand it to be your opinion that the best means of stopping plague is to separate the people from the plague poison?—Certainly.

17,727. The plague poison being located in the houses?—Yes, mostly.

17,728. Then it is a good thing to take the people out of their houses?—Yes.

17,729. Having taken them out of their houses you would, I suppose, disinfect the house as thoroughly as you possibly could?—Yes, that is reasonable, of course, though it does not do very much good.

17,730. Do you think that disinfection does not do good?—I will not say that, but is it possible to disinfect, say, a six-storeyed house? I could show you a six-storey house with 2,000 people living in it, and I would be ready to bet the Commission 50 guineas that they cannot disinfect it.

17,731. Having removed the people out of their houses and got them away from the plague poison what further measure would you take with them?—Now, you come to the question which I put before the Medical and Physical Society, that we must divide the places—a big city like Bombay would be first, then a city of 50,000 inhabitants and so on, going down, because the more you go down the more manageable the whole thing becomes.

17,732. Do you consider that the main object should be to get the people away from the infected place and to destroy the infection in the place?—I think the far better plan is not to have the plague at all. I see I have wasted a great deal of my time in the last three years in seeing how we can cure it. Now, I have left off therapeutics and want to confine myself to the question of how to stop it.

17,733. When plague has come, do you think that the best way to stop it is to clear the people out of the infected neighbourhood and to disinfect the houses?—Certainly; doing the best you can to clean up.

17,734. (*The President.*) You think the best thing to do is to protect a town from plague; what would you do in such a place as this to prepare it against plague?—Rebuild it, I suppose, just as we are doing. I believe we are going to show the world an advance in sanitation which neither Glasgow nor Manchester nor Birmingham nor London had. They have only done it in part, and I believe we are going to do it as a whole in this city.

17,735. (*Mr. Cumine.*) You think that running away is the best thing to do?—If you are not immune.

17,736. But people do not begin to run away until a certain number of deaths have occurred and plague has taken hold upon the town; is not that so?—That is so to a certain extent, but feeling acts upon feeling, people

Dr. T. Blaney.

13 Feb. 1899.

in a house act upon people in a house, and people in the street upon people in the street.

17,737. Did not the exodus begin after the plague had taken a pretty firm hold upon Bombay and a lot of people had got infected?—Yes.

17,738. So that probably a large number of people who ran away carried the plague with them?—Yes, probably.

17,739. Is not that a very dangerous thing for India at large?—I think we have made too much of that; India at large cannot be attacked. They say there is no history of plague along the valley of the Ganges.

17,740. So much plague as there is in the Bombay Presidency at this moment has all been carried by people running away from Bombay, has it not?—It is probable it is so. 12 years ago I saw the approach of this sanitary calamity—I could not give it the name of plague. I was in the habit of keeping a mortality record for 30 years, and I saw that the mortality of Bombay was going up and up. When I went to the trade districts I found the trade increasing, the godowns increasing, the rats increasing, every abomination increasing, and over-crowding increasing, because the ground was valuable and the place was necessary for the people to get their living. I went to the Corporation and proposed a loan of 60 lakhs of rupees to improve Mandvi. There it is, on the records of the Corporation now. I only lost that by three votes. They said I was the most extravagant man on the Corporation, but if I could have used the word "plague," if I could have said, "Gentlemen, you will be attacked with plague if you do not give that money" I should have got it, and Mandvi would have been a different district, and perhaps none of us would have been sitting here to day. I saw a sanitary calamity coming into view, but what the name of it should be I could not say.

17,741. I think the word "Jain" is used in a loose sense in Bombay, is it not?—No, not in a loose sense, but in a compound or conjoint sense. A Jain is a man whose religion consists in not destroying animal life, and in that coterie there are the Marwaris and Banniahs —altogether 15 or 16 classes.

17,742. Does not the word "Jain," as used in Bombay, include people who are not of the Jain religion but of the Lingayat religion?—I am not quite sure of that, but the Lingayas are only a population of 3,000.

17,743. These Jains, which you describe as people who will not destroy animal life, are quite a small proportion of the total number of Jains, are they not?—No, I do not think so; I think the registration of 25,000 is correct.

17,744. To explain the figures which you have given you attribute a great deal to diet. But have you made proper allowance for the relative exposures to infection which the European has, for instance, and a Bhatia who lives in Mandvi?—That cannot be shown in a table.

17,745. But in your own mind have you allowed for the difference? There is a great difference in the *chances* of infection, between a European living on Malabar Hill and a Bhatia living in Mandvi, is there not?—Most certainly, and if you take two chawls, one containing 200 people and another containing 50, there is a great difference between them also.

17,746. (*Prof. Wright.*) What steps ought, in your opinion, to be taken to detect plague cases in this city?—I do not think any.

17,747. Do you think doctors ought to be called upon to report plague cases in their practice?—Yes, that is reasonable. We have had that law in force here, and I myself have observed it most rigorously, though I believe I was the only man in Bombay who did so 30 years ago. I have always reported them, even cases of puerperal fever. I think it is quite reasonable.

17,748. Do you think that corpse inspection is reasonable?—I think the Health Officer should have some voice in matters of that kind, because he is held responsible if a serious epidemic arises.

17,749. Do you think that corpse inspection ought to be resorted to in order to detect cases of plague?—Where? That is a very important question. Do you mean at the cemeteries or at the houses?

17,750. At the cemeteries say?—Yes; at the cemeteries you may examine as much as you like. If the Municipality had properly managed the thing, and there had been proper medical men at the cemeteries, the people would never have objected at all; they would have allowed inspection and examination to be made and proper reports of the causes of death. I do not make that statement without the very greatest authority. I was Coroner of this City for 17 years, and, in doing my duty, I have been at these burial and cremation grounds continually, and I have never found the slightest difficulty in finding out everything connected with the case of death there. And that was not because I was Coroner, for my own subordinates could also do it.

17,751. Do you think the patients would give you the right addresses at the cemeteries?—Oh, yes. The police have proved that in their statistics for the last 25 years. We have a double registration here. Were it not for the police and the Municipal registration our figures would be absolutely worthless. At present we look upon the total mortality as correct, and it is correct, and it is correct because the police have to furnish the Commissioner of Police with separate returns every day of every case.

17,752. I understand there is a difficulty experienced in finding out the houses where plague deaths have occurred?—There may be a little in a big city like this.

17,753. Can you see any way of avoiding that difficulty?—I think the Commissioner of Police should tell his sepoys that any increased pay or promotion which they may be looking forward to will be stopped unless the information is obtained. I believe that would stop it immediately. There has been no considerable difficulty with the police in getting all the information which they require, but they were non-professional people and they could not get the causes of death. Here we have to be with a sort of quasi-professional people whom they call Hospital Assistants, and who possibly might be able to diagnose diseases, but they have done nothing; they were hand and glove with the people as far as the statistics seem to show.

17,754. (*Mr. Cumine.*) Can an ordinary coolie tell you the number of the house and the street in Bombay in which he lives?—No.

(Witness withdrew.)

Adjourned till to-morrow.

At The Secretariat, Bombay.

FORTY-SEVENTH DAY.

14th February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. ISMAIL JAN MAHOMAD called and examined.

Mr. Ismail Jan Mahomad.
14 Feb. 1899.

17,755. (*The President.*) You are a Licentiate of Medicine and Surgery?—Yes.

17,756. And you are also a member of the Municipal Corporation?—Yes.

17,757. How long have you been in practice?—This is the 13th year of my practice.

17,758. You have been here all the time of the plague?—Yes.

17,759. What is your opinion as to when the first cases of plague occurred in Bombay?—I think it was about the beginning of August 1896.

17,760. Did you see any cases about that time yourself?—I saw two cases, which I did not diagnose as plague, but which I now think were pneumonic cases of plague. After that I saw two cases with glandular enlargements, and when I saw these cases I communicated with the Health Officer, and told him that I had noticed two cases with high fever, delirium, and enlarged glands in the neck. That was about the 15th or 16th of August 1896.

17,761. You saw two cases before that, you say, which you now think were cases of pneumonic plague. Can you tell us what symptoms those cases had, and why you think now that they were pneumonic cases?—The first of these two cases, of the pneumonic type, was a Multani, who had returned from Nasik. On his return he had fever, and when I saw him his temperature was about 104 degrees, and he was delirious. I examined his lungs, and found no dulness, but there were fine crepitations, and I thought that the symptoms were too severe for a case of broncho-pneumonia, the delirium having come on so soon as that, and being followed by a fatal result within 36 to 40 hours after I had seen him.

17,762. What is the other case?—The other case was also in the same firm—in the same house. He also had been to Nasik, but he did not come back sick. He developed fever after his return here; he was a young man. They sent for me at once, and when I saw him first he had a temperature of 105. In the evening, when I saw him again, he developed the same symptoms of pneumonia, and died within 36 hours.

17,763. Had these cases any relationship with each other?—They were in the same house.

17,764. How long had they been in Bombay?—They had gone from Bombay to Nasik for a pilgrimage. They stayed there for five days, and then returned to Bombay.

17,765. How soon after their return did they die?—One of them returned with fever after his stay at Nasik for five days; and the other developed symptoms of fever after the death of the first. In fact, both the persons died within a week's time.

17,766. What is your view as to the origin of plague here?—When I first saw plague here, I thought that the condition of Mandvi at the time was so filthy, and the houses were so very much overcrowded, that that was the immediate cause of the outbreak. The condition was so filthy that nearly 1,200 cartloads of sewage and filth material were removed from the Mandvi drains at that time. The houses also were very much overcrowded, each room containing five to eight people—a small room of about 10 feet by 16 feet. Although these rooms are well ventilated, still there was very much overcrowding in them.

17,767. Were these rooms in chawls or not?—They were in big houses.

17,768. Not chawls actually?—No, the first cases were in large well-ventilated houses.

17,769. The first cases were the imported cases from Nasik, I understand?—I do not think those were imported cases myself, as I changed my mind afterwards. My first impression was that those two cases were imported cases from Nasik, but subsequently I found out, when I went to this place to treat those Multanis, that there was already a scare among the men in the firm, and many of them were running away from Bombay.

17,770. You said that one of the cases already had fever when he arrived from Nasik?—Yes, but he had left Bombay only five days previously.

17,771. Was there any plague in Nasik at this time?—No, there was no plague at Nasik at all at that time, and plague did not develop in Nasik until last year.

17,772. Will you proceed with your opinion as to the origin?—When I saw those two cases my first impression was that perhaps those cases were imported, but I found out that there was already a scare among those people, and not only that Multanis in that firm, but Multanis in other firms in Bombay, had run away; and I heard that, a fortnight before, there was plague occurring among these people, just about the beginning of August. About six weeks ago I was talking with a resident of Mandvi, and inquiring as to whether anybody had noticed where the dead rats first were found, and I was told that they were found in godowns containing Chinese goods. At that time my attention had not been directed to the fact that there were godowns containing Chinese goods at Mandvi, and I found out that in Argyle Road there were three godowns containing Chinese crackers. These Chinese crackers come from Hong Kong.

17,773. What are the crackers that you refer to—the crackers that you pull or those you eat?—Yes, they are the crackers that you pull. There were also other godowns containing tea and sugar and china silk at Mandvi; and I was told that in one of the sugar godowns dead rats were found.

17,774. That was before these cases you have told us of?—Yes. Curiously enough, on further inquiry I found that these two patients lived in a house which was adjoining one of these godowns; and I found that there was another godown just at the back of this China goods godown; there was a granary, and a number of dead rats were found in that granary, and several plague cases were found in the house on the top of that granary.

Mr. Ismail Jan Mahomad.
14 Feb. 1899.

17,775. To what conclusion do these facts lead you?—They lead me to conclude that the poison must have been brought with the goods either in the form of fomites, or, perhaps, a dead rat, which may have infected the rats in that locality; and thus the rats of the locality being infected, they communicated the disease to men. The dwellings in that locality were particularly such as to make these rodents take up their habitations in them; the houses were dirty, and rats made them their hiding places. I believe if a sick rat died in a place where there was a lot of rubbish concealed, the presence of that sick rat dying of plague in that place would communicate the disease to human beings, either through the poison being in the air and thus communicating the pneumonic form of plague, or, perhaps, by the residents walking bare-footed, and getting themselves infected through cuts. I have noticed several cases in which such cuts were the cause of infection.

17,776. You have not told us your opinion as to the manner in which the rats first acquired their infection?—I think it came from either a dead rat or fomites brought in the goods from Hong Kong.

17,777. You think China was the origin?—Yes, I think China was the origin, because particularly at that time, in the month of August, crackers are imported for the Diwali purposes, and also for a Muhammadan festival where crackers are used; and I think Hong Kong has thus a direct communication with Bombay.

17,778. Have you considered the other possible positions from which plague might have been imported?—Yes, I have considered those conditions. It has been said that perhaps it has been imported by Sadhus bringing down the plague from Upper India, and from Nasik. I think there are strong arguments against such a theory. First, as regards Nasik, there was no plague at Nasik at that time at all. We did not hear of plague at Nasik until the next year—the second epidemic—and then, as I said before, there was already a scare among the residents at the time when those two cases occurred, and those residents had never been to Nasik at that time.

17,779. You think the Sadhus have nothing to do with the carrying of plague?—I do not think so, and another thing also is, that if the Sadhus had anything to do with plague, the Sadhus would have communicated it on their way at many other places before they communicated it to Bombay. There was another curious thing about plague at Mandvi, and that is, that for about a month or so plague was confined to a particular locality of Mandvi, just below the Masjid Bridge, showing that the poison was there among the rats in that locality. Now that locality is separated from the other locality by a big railway line, and for one month not a single case occurred, till people were allowed to remove from that place and go and live in the centre of the crowded locality of Mandvi. I believe that in that way it was spread both through rats, as well as through human intercourse, to other places. I noticed in two cases that people suffering from plague, who were living at Mandvi, were taken to Khetwadi. There was not a single case of plague up to that time there. When these two persons were taken there, they died. After their death, for some time no case of plague occurred, but, 15 to 20 days afterwards, dead rats were found in the locality; and after the appearance of dead rats, plague spread; so that I believe that in that case plague was first conveyed from Mandvi to Khetwadi by these two people being carried there. They infected the soil there, and rats were infected from that. Similarly at a village of Versova, where I used to live before, a case was taken there and concealed. He died there, but nothing of plague was heard there for about 20 days, when dead rats were found, and after that plague broke out. I think, therefore, that plague is conveyed from one place to another by human intercourse: first, a plague case is carried there, that infects the soil, and then rats are infected. I believe rats have a good deal to do with the spread of plague.

17,780. In regard to the infection, how do you think that enters the human body?—I think one of the modes is through cuts—direct inoculation—and I have noticed several plague cases where there was a small cut on the foot. The pneumonic form of plague is generally acquired through the air. I have noticed in some cases attendants getting it. In the case of Dr. Manser, and also of some of my private patients I have noticed that.

17,781. Where it is produced by breathing an infected atmosphere?—Yes.

17,782. In those cases where you have observed a lesion of the feet, or of a foot, on which side, and where, did the bubo occur?—I have not particularly marked it, but my impression is that it was generally on the right foot.

17,783. If the lesion was on the right foot, where would the bubo be generally?—On the right side.

17,784. The bubo was generally on the same side as the lesion?—Yes.

17,785. Have you any instance in which a pneumonic case appeared to have been produced from a bubonic case?—I have not particularly noticed such a case, but I believe it to be quite possible.

17,786. You have no facts?—No.

17,787. Have you any instance in which a bubonic case has been produced from a pneumonic case?—I cannot produce any facts.

17,788. You have facts which show you that pneumonic cases may be produced from pneumonic cases?—That I do say.

17,789. Have you facts which show you that bubonic cases may originate from bubonic cases?—I do not think that the mere remaining with a bubonic patient would give rise to a bubonic case. I do not think that plague with a bubo is communicated through the atmosphere.

17,790. There is no immediate communication?—No.

17,791. It must be communicated through the soil to the person who is infected, you think?—Yes.

17,792. Have you had much experience of Haffkine's prophylactic fluid?—Yes, I have.

17,793. Please to state generally the results of your experience?—In my dispensary, about 996 people were inoculated by my partner with Haffkine's fluid. I have done several. I have the records of these here, and I know the after history of most of them. Out of these 996 cases, there were 39 cases where the inoculation was done before the age of five years, there were 10 cases in which inoculation was done after the age of 60 years, and there were 947 cases in which inoculation was done between 15 and 60. There were three cases in which plague developed after inoculation. In one case plague occurred two days after inoculation, in another it occurred 29 days after inoculation, and in the third case it occurred 18 days after inoculation. The one who got plague two days after inoculation recovered, the other two died; but inoculations were performed in such a class of patients that I believe if it had not been for inoculation, many of these 996 cases would have succumbed of plague.

17,794. Were these cases selected in any way?—No; those who used to come to our dispensary were inoculated.

17,795. They came voluntarily?—Yes.

17,796. Do they represent the very lowest, or the middle, or the higher classes?—From the lowest to the highest; all classes.

17,797. Many of them lived, therefore, in the worst sanitary conditions?—Yes.

17,798. And others in good sanitary conditions?—Yes. In addition to the inoculations in our own dispensary, of my own community about one-half were inoculated at H. H. Aga Khan's bungalow, Khushroo Lodge. Still, I used to take a great deal of interest in knowing the after results of these, and I have collected all the figures of the inoculated, the number of cases in those inoculated once, and the number of cases in those inoculated twice. I have got them here, and I will present them to the Commission.* Professor Haffkine has submitted his report† about the first period of inoculation from 20th December 1897 up to the 20th April 1898. I have tried to verify all the results given in that report, and I find that the names of the people inoculated, and the results, are all perfectly correct. After that date, that is from the 20th of April 1898 to December the 21st, 1898, about which M. Haffkine has not submitted a report, I have

* *See* App. No. LV. in this Volume. A report by Dr. Khaja Abdulla regarding cases of persons treated in the Khoja Hospital, Bombay, with a list of inoculated cases, is published as App. No. LV. (1) in this Volume.

† *See* App. No. IV. in Vol. I. of the Commission's Proceedings.

tried to collect the figures, and I am glad to say that the results are more encouraging than for the previous period.

17,799. How many cases were inoculated in this last period which you speak of?—About 5,000 are inoculated, and the other 5,000 are not inoculated.

17,800. What other 5,000?—The Khoja community consists of about 10,000 people.

17,801. There was no selection made for inoculation, was there?—There was no selection, and I think that the Khoja community presents an aspect about inoculation which ought to be instructive for others. In fact, among the Khojas, 90 per cent. of them live at Mandvi, the place where plague first began. Many of this 90 per cent. are middle-class Khojas living in overcrowded chawls and houses, most of them living under the same circumstances, and often in a family some of them are inoculated, and some of them are not inoculated. There are instances of inoculated and uninoculated persons living under the same roof, and under the same circumstances, in which those who were inoculated escaped being attacked with plague, and those who were not inoculated got plague. In the case of my brother's son, who was not inoculated, he got plague, while the others, who were inoculated, all escaped.

17,802. How many others?—Nine.

17,803. Living in the same house?—Yes, I can point out many other instances of that in the Khoja community, in which people living under the same roof, and under the same circumstances and conditions of life, escaped among the inoculated, while those not inoculated got plague. There are two instances which I specially want to bring to your attention. The first is that of a boy of about eight years of age. He got plague a week after he was inoculated a second time. He had a big bubo in the groin, and when I saw him his temperature was 105. I inquired of the parents whether there were any cases of plague in the house, and the answer was that this second inoculation was done because dead rats were found in the house.

17,804. How long after the first inoculation was the second inoculation performed?—It was about 10 or 12 months after the first inoculation. The second inoculation was done because dead rats were found in that house. On further inquiry I found that there was another man who was suffering from plague in the same house. This boy, who was inoculated, recovered; the man who had plague, and was not inoculated, died. Now, this first boy, who was inoculated, and who got plague, recovered. It was a genuine case of plague—I do think his recovery was due to inoculation, and I believe, if he had not been inoculated in time after the dead rats appeared, that, perhaps, he also would have died. There was another similar case in which symptoms of plague developed after the first inoculation, and in which case also the inoculation was done because dead rats were found. This case also recovered, but I believe, if he had not been inoculated in time, that, perhaps, he would have been the worse for it. As to the second period of inoculation among the 5,000 Khojas, I have calculated that out of the 5,000 that were inoculated between the period of April the 21st, 1898, to December 21st, 1898, there were 22 cases of persons who were inoculated, who got plague, and died of it; and there were 26 cases of persons who were inoculated, and who died of other diseases. There were 218 of the non-inoculated who died of other diseases, and there were 44 of the non-inoculated who died of plague.

17,805. In addition to the 218?—Yes. Now, the average mortality among the Khoja community, taking the average of five normal years, is 342, about one death a day; and the average normal mortality for the eight months that I have selected for my calculation would be about 230. Now, I have said about half the community were inoculated, and half not inoculated. 5,000 were inoculated, and 5,000 were not inoculated, so if there is a normal mortality, then we would have 115 deaths in the inoculated persons from ordinary causes in ordinary times. Instead of that, we have got only 48 deaths, so that we get a mortality even lower than the normal mortality.

17,806. That is less than half?—Yes. Now let us take the uninoculated. We have got among the uninoculated a mortality of 218 and 44, a total of 262. Instead of 115 we get 262 there. I have tried to verify these figures from our jamaat books. Our community has a record kept, in which the name of every person dying is given, because the community gets a certain amount of fees for every death, so that the figure for total mortality which I have given here of all the four, 310, is a figure which is quite correct. I have taken it from the books of the jamaat or community. Now, as regards the figures I have given you of people suffering from plague after inoculation, 22, that is approximate; but I think that there are actually less deaths from plague among the inoculated than the figure that I have given you. When I say that, I say it for this reason, that up to this time in the jamaat book there is a record of only four cases of the inoculated dying from plague. I have put it down as 22, because, from my investigation, I found that there were some cases which were put down as brain fever by the practitioners, which were actually cases of plague, so I have added to the original figure 4 18 more of suspicious deaths after inoculation, and so have brought the figure up to 22, but I believe, if careful notification was made, the number of plague cases after inoculation would be even less than 22. In the figure of 218, which I have given of persons dying from other diseases among the non-inoculated, I can find among those many cases of people who have died of plague, but who have not been returned as dying of plague, but from other diseases—as many as 90 out of those 218. If we take all cases of brain fever, and some cases of phthisis, then I think that as many as 90 may be deducted from those as having died from plague. I am now carrying on my investigations in verfying these figures, and I want to bring them out just when Professor Haffkine brings his own figures out.

17,807. So that you think the number of plague cases was erroneously increased by wrong entries?—Yes.

17,808. How do you account for this remarkable difference in the mortality from causes other than plague in the non-inoculated, as contrasted with the inoculated?—I think the non-inoculated death rate has increased in comparison to the inoculated, because several weak people do not get inoculated, and inoculation is not done in very young children, in whom there is a heavy mortality.

17,809. There is a high mortality in the very young?—Yes, at present there is a great mortality in the young children, and that may account for the large majority; but I think there is some protective property in inoculation against other diseases also. I have not noticed up to this time in my community any complaints about the after effects of inoculation. I have found in some cases, where reaction was strong, that people suffered from loss of appetite and weakness, but after a time it passed off. I lately had a case where I re-inoculated a maid servant in a family. She would not undergo inoculation last year. She was suffering from a severe headache for many years. Curiously enough three or four days after inoculation the headache entirely disappeared.

17,810. Has she remained free?—Yes, I inquired yesterday, and it is quite gone.

17,811. What other affections do you think are benefited by inoculation?—I have no facts with regard to that; but my impression from the figures is that it has some effect.

17,812. You think the mere exclusion of the very old and the very young will not chiefly account for it?—I do not think it would entirely account for it.

17,813. Can you give us the ages of the 5,000 who were inoculated in this community, and of those who were not inoculated?—They are not absolutely correct figures. There may have been 200 more or less. Our census is also not very accurate, but I believe that 10,000 is a fairly correct figure.

17,814. In the case of the 5,000 who came directly under your notice, can you give us the age of each of those who were inoculated?—I do not think I can give the age.

17,815. What ages did you exclude in inoculation as a general rule?—When I was practising inoculation, I used to avoid persons who were very weak in constitution, whatever age they might be. I would inoculate an old man of 60 or 65 if he had a good constitution.

17,816. I thought you placed importance on the fact of the young and the very old being excluded, in accounting for the higher mortality in the non-inoculated?—I excluded a great many, and others also, perhaps, remained away themselves.

Mr. Ismail Jan Mahomad.

14 Feb. 1899.

17,817. You inoculated all who presented themselves if you found them sufficiently strong?—Yes.

17,818. Age was not a barrier?—No.

17,819. That was your experience of a part of the 5,000; what was your experience of the remainder of the 5,000?—The remainder of the 5,000 were not inoculated.

17,820. I mean those that you did not yourself inoculate?—I have not inoculated these 5,000. Those were all inoculated at H. H. Aga Khan's bungalow at Khushroo Lodge. I have been among these people from the beginning, and I have been getting out of the jamaat books how many persons were inoculated, how many were not inoculated, and how many died after inoculation, and so on.

17,821. Will not these books show you also their ages, and when they were inoculated?—No.

17,822. Was there no distinction between an infant and a grown up person?—No.

17,823. Have you had any experience with regard to the curative treatment of plague?—Dr. Yersin was requested by me to see a case at the Connaught Road Khoja Hospital of a patient who was picked up in the road. Dr. Yersin saw the patient, and he pronounced the opinion that the case was very bad, and he would not inoculate the curative serum. I showed him another patient who was admitted that very evening, and he inoculated that patient, and the inoculation was continued for three days successively. On the fourth day the fever of this patient who was inoculated with Dr. Yersin's curative serum was less, and the patient was on his way to recovery. At the same time the other patient, whom Dr. Yersin refused to inject, was also getting on well.

17,824. That was the patient whose symptoms were apparently more severe?—Yes.

17,825. Have you any other experience?—Yes, I have two other cases that I placed under Dr. Yersin, in the Khoja Hospital, but unfortunately they both got bad and died.

17,826. Was much serum injected?—Yes, each of them had serum injected every day for three days, morning and evening.

17,827. In what day of the illness was the treatment commenced?—One of these two cases was on the first day; the other case was on the second or third day of of the illness. I have noticed four other cases under Dr. Yersin. They were not my cases, they were in a neighbouring hospital. There were five cases altogether—four died and one recovered.

17,828. Was your experience satisfactory or unsatisfactory?—My experience was unsatisfactory.

17,829. You made some reference to insanitary conditions not being accountable for the production of plague. How far do they affect or increase the virulence of plague, assuming it has been introduced into a locality?—I think insanitary conditions conduce to make the plague more virulent, and cases would end fatally. There would be no chance of recovery for people suffering from plague, and living in insanitary houses.

17,830. As to the influence of insanitary conditions on the amount of plague, what do you think of that?—I think that with insanitary conditions plague will certainly increase.

17,831. Have you any facts which will bear out that opinion?—I know of several houses in which one case of plague has occurred, and because the house was not in a sanitary condition the whole number of the people living there—they did not vacate the house—became victims of plague, and died.

17,832. Is it your opinion that people living in insanitary houses are more easily affected?—Yes.

17,833. You said that the plague appears to be very virulent in such houses, or, at least, that the chance of the recovery is less?—Yes.

17,834. As to the localities in this city in which plague has been most prevalent, have you been able to trace any relationship between that prevalence and the sanitary conditions?—As I said before, both Mandvi and Kamatipura are known as the haunts of plague. In Mandvi there are big and well-ventilated houses, but the sanitary condition as regards the drains is very bad, and there is overcrowding in the houses. As regards Kamatipura, the houses are all low, the ventilation is not good, and there is overcrowding there, too.

17,835. These, you say, have been the chief haunts of plague?—Yes.

17,836. Are these the most insanitary quarters of Bombay, or not?—Kamatipura is the most insanitary quarter of Bombay. Mandvi is not so insanitary; but I think Mandvi remains the haunt of plague for some other reason.

17,837. What other reason?—One reason is because the granaries are there, where there are a number of rats. I believe if there was a single house which contained infection, as soon as there is a colony of new rats, they get themselves infected, and spread the plague. After the plague has been over the place, and all the rats are dead, for the time being the plague subsides. Then there comes a fresh colony of rats.

17,838. A fresh importation?—Yes, and they get themselves infected, and plague spreads.

17,839. Have you anything to say with regard to curative serums?—I treated one case with Dr. Lustig's serum. In that case the effect was very good. The patient, a Khoja lad, suffered from fever and a bubo in the groin. I saw the patient. I found he had eczema on the legs, and I thought the enlargement of the gland was due to that. I treated him for one or two days, and he got well. After a month he again got fever, his temperature going up to 105 degrees. He had a small gland just on the side of the chest. On this occasion there was no eczema, or anything to account for the gland. As this patient had been visiting another plague patient, I had grounds for believing that the lad had plague, and I immediately sent for Dr. Galeotti. Dr. Galeotti's Assistant, Dr. Polerini, came and injected the serum. He gave no other treatment, except injecting the serum. For three days the lad had fever.

17,840. Was the serum injected twice a day?—Yes, twice a day. The fever subsided on the third day. Then, again, after three or four days the fever increased, and the bubo suppurated. Then it was opened, and a big characteristic slough of plague gland came away. I think this was a typical case of plague, and that the cure was due to Professor Lustig's serum.

17,841. Was that the only case in which you used Dr. Galeotti's serum?—Yes.

17,842. I understand that in the other cases Yersin's serum was used?—Yes.

17,843. (*Mr. Hewett.*) Among the uninoculated who died, I see as many as 47 were under one year of age?—Yes.

17,844. Whereas among the inoculated who died there were only two?—I have not calculated the figures.

17,845. I shall be glad if you will give me the following information:—1st, the number of inoculated that died under one year of age; 2ndly, the number of uninoculated that died under one year of age; 3rdly, the number of inoculated who died between the ages of one and five; 4thly, the number of uninoculated who died between the ages of one and five; 5thly, the inoculated who died being over 60 and under 70; 6thly, the uninoculated who died being over 60 and under 70; 7thly, the inoculated over 70 who died; and, 8thly, the uninoculated over 70 who died?—The following figures show the number of deaths in the Khoja community at different ages amongst the inoculated and uninoculated. The number of deaths of children inoculated under the age of one year is one only: the number of deaths among children below one year not inoculated is 57. The number of deaths amongst children inoculated between 1 and 5 years is 7; and amongst the non-inoculated between 1 and 5 years is 33. The number of deaths amongst the inoculated between 60 and 70 is 2 only, and amongst the uninoculated 28. The number of deaths amongst the inoculated over 70 years is 2, and amongst the uninoculated 8 only. The above figures show what advantage the inoculated have over the uninoculated at different ages. It would be interesting to know how many were inoculated at the different ages, but unfortunately the jamaat has not got such a record, but I suppose Prof. Haffkine must have got such a register.

17,846. (*Mr. Cumine.*) You gave us two sets of figures; one set you got from the Jamaat book: where did you get the other set from?—I got the other figures after verifying some of the cases myself. I went and

made inquiries in the families, and I found that several of those who were reported to have died of other diseases, actually died of plague.

17,847. Were you ever supplied with a register of the names of all the people who had been inoculated?—No.

17,848. In going through the jamaat books, how did you know, as regards each death entered, whether the person was inoculated or not?—Since inoculation has been introduced great care has been taken in inquiring whether a particular man who has died was inoculated or not, and how many times he was inoculated.

17,849. But you did not test to any extent the correctness of the entries in the jamaat book—you had no register of inoculated persons to refer to?—I had no register; but by visiting the families, and making inquiries, I was able to find out whether a particular person mentioned in the book had been inoculated or not.

17,850. But supposing an inoculated person had died, and his death had never been put down in the jamaat book at all, how would you have known of it?—It is impossible that a death could not be put down. The jamaat book is most accurate.

Mr. Ismail Jan Mahomad.

14 Feb. 1899.

17,851. Did you keep any note of how many persons there were in each of those houses so visited: how many persons were inoculated, and how many uninoculated; and how many attacks and deaths there were amongst the inoculated and uninoculated respectively in each house?—I have not got a register of that.

17,852. (*Mr. Hewett.*) Did you attend a man named Narayan Mulji for plague?—I attended Narayan Mulji for axillary abscess, not plague.

17,853. Did he have more than one attack of plague?—He did not suffer from plague at all.

17,854. Please give date and details?—The axillary abscess was opened in 1896, this had left a sinus which suppurated after a couple of months and was opened again.

17,855. What was the position of the buboes in each attack?—The abscess reformed in the same axilla.

(Witness withdrew.)

Mr. George Lund called and examined.

Mr. G. Lund.

17,856. (*The President.*) I believe you are a merchant?—I am in business in Bombay.

17,857. Have you had much to do with plague measures?—Yes, a great deal, for more than twelve months, day by day.

17,858. (*Mr. Hewett.*) Would you specify the districts in which you have been working as a volunteer?—I have been working in the Mazagaon and Tarwadi districts, more particularly just recently in the latter.

17,859. What is the character of the population in those districts?—Principally Ghatis. The population at the last census was close on 55,000: at the present moment it undoubtedly is considerably in excess of that number. In the southern portion, the people are principally Ghatis by caste, labourers and cartmen, living from hand to mouth, and employed in the docks and Mandvi; there are also Portuguese and some fisher folk. In the northern part there are cartmen and mill hands, with several large colonies of Parsees and Muhammadans located here and there all over the districts.

17,860. Is the district a very congested one?—Some parts of it are very congested, particularly at the present time.

17,861. What was the state of the public sanitation when the plague broke out?—The public sanitation was, and is at the present time, not at all good. It is most unsatisfactory, owing to a considerable portion of the district being at so low a level that lifting must be had recourse to to deliver the sewage at the outfall at Mahalakhshmi. The necessary works are now being vigorously pressed on, but it will be some time yet before they can be completed. At the present time the sullage water passes into the side drains, many of which are in a very worn and offensive condition. This, I consider, to be one of the great objections and difficulties in the neighbourhood. The night soil is collected into carts and discharged into a drain for outflow into the harbour, causing a great public nuisance. The domestic sanitation of the district is on the latrine and basket system. Many of the latrines are ill-ventilated and in a very unsanitary condition. The Health Department of the Municipality do all they can to remedy the evil, but owing to the apathy of the landlords, and the unwillingness of Magistrates to inflict adequate fines, the nuisance in a great measure remains unabated. There was one case in which a landlord was had up before a Magistrate for the third time on account of an overflow of a most objectionable character from latrines. He was only fined two rupees. He can go on paying two rupees as long as ever he likes. It is cheaper to pay fines than to make alterations.

17,862. Did you experience any difficulty at any period of the operations in ascertaining the number of plague cases?—We have always found more or less difficulty, particularly under the Plague Committee; they were secreted very considerably under the Plague Committee.

17,863. To what do you attribute this difficulty?—To the harshness of the measures carried out. In a city like Bombay, with a large population, the more rigorously you try to enforce your restrictive measures, the less, I think, you will succeed.

17,864. Can you give us any definite instance in which the effect of these measures was to cause people to disappear?—Yes. On the Port Trust Reclamation on the Reay Road people were hidden in stacks of wood. One Sunday morning we found four people hidden in that way. Stacks had been built up, and big balks of timber and trunks of trees had been moved, and the people covered in so that we should not find them. I may cite one instance on the Telang property. There was a large block of chawls there. I asked whether I might be allowed to vacate it in my own way. The Plague Committee said no, a regular authority had been provided, and it must be done by them. I said, "Very well." The result was that the soldiers and sailors arrived, the building was surrounded, and when we went inside, the whole of the inhabitants, numbering about 300, had entirely disappeared, except two men who were suffering from plague right up at the top of the house. One died before he could be removed, and the other died shortly afterwards.

17,865. Is the objection of the people to the removal of the sick, or to the segregation of the healthy?—It is going to the hospital. They do not like it. It was in consequence of that, that in conjunction with some other gentlemen who kindly assisted me, we started a hospital for this Telang property in which we treated patients. Profiting by the experience gained in the previous year in the attempt at segregation in the Telang property, which consists of six large blocks, a local hospital was established for the use of the inmates. Thirty-seven patients in all were treated in the six weeks it was necessary to keep it open. I consider at the present time, with the building ventilated so much, that there is no indigenous plague in the chawl. We have had some few cases from time to time, but they have been people who have contracted the disease outside. They have probably contracted the disease while at work. They have come home and have been so sick that they have not been able to go to their work any more, and have died in the place. The reason why I do not think there is any plague in the chawl is because the women do not get it, it is almost exclusively confined to the men who are employed in work. As I have already said, 37 patients in all were treated in the six weeks it was necessary to keep this local hospital open. Of 22 cases of relapsing fever and other diseases, one sufferer died, the others all recovered. Those who, from poverty and the consequent necessity of continuing their daily labour till the last possible moment, were not discovered till it was too late for treatment to be of any avail, died. Large numbers of houses and buildings in the district have been reported to the Municipal Executive as insanitary, and many of these have been condemned and destroyed.

17,866. Do you think that you now get the majority of cases reported to you?—We get more than we did, but at the same time there are a good many cases everywhere being secreted.

17,867. Is it your experience that the majority of cases are reported to you when the people are still sick, or

Mr. G. Lund.

14 Feb. 1899.

after they are dead?—We get a great many sick cases reported to us, I think I may say that the majority of cases are reported to us before they are dead.

17,868. That is an improvement?—Yes, with regard to my own district, I certainly think there is a decided improvement.

17,869. Have you, in your district, resorted to the practice of treating sick persons in their own houses?—Not many in my own immediate district. It was done, however, by Mr. Firth in the "E." ward on the other side of the Parel Road. We have treated two or three cases in that way, but not to the extent that Mr. Firth has done.

17,870. Have you had an opportunity of observing its effect in Mr. Firth's district?—In not one of the cases has the disease spread, nor has it spread in my own district. At the present time I have one such case in the Telang property, and the people immediately in contact with the case have not been infected at all.

17,871. Have you disinfected the house in which you have allowed this patient to reside?—We disinfected each floor before the recrudescence began. We have opened out holes through the floors from top to bottom.

17,872. Did you take any other measures?—We inoculated all the people in the same room with this man, and we cautioned the other people not to go into the other room. We told them that if they did go there we should be obliged to send them to camp, and as far as we can judge I do not think the people have gone there. We have, from time to time, gone there unexpectedly, but we have never found more than the two attendants with him.

17,873. Have you disinfected the house since the case occurred?—No; we shall do that afterwards. We use disinfectants, however, in the room at the present time.

17,874. In a case like that, when you allow a sick person to remain in the house, would it be possible to disinfect the remainder of the house?—Certainly.

17,875. But you have not done so?—No, because I do not think it is necessary. The plague is not in the house. The man did not contract the plague there; he got it when he was at his work at Mandvi.

17,876. The only room in this particular house which you regard as infected is the room in which the patient is residing?—Yes. We shall disinfect that room, and the other room next to it. If we have another case we shall disinfect the whole floor. When, however, there is only one single case we merely disinfect the room itself, and the rooms immediately in contact.

17,877. I believe you have had some experience with regard to inoculation?—I have.

17,878. Would you give us the facts that have come under your notice?—Inoculation has been encouraged in every way. Contacts are given the option of being inoculated or going to camp, and opportunity is taken of a clear or doubtful case of plague occurring in a building, to persuade as many inmates as possible to submit themselves to the prophylactic. Of the total number of persons inoculated by the medical officers in the district, and at their dispensaries, up to date—close on 7,000, whose names and addresses are known and noted in the office books—one death only from plague has occurred, and one of complication—in the Telang property—high fever, vomiting and purging, which was successfully treated in the local hospital. In one chawl in Victoria Road 103 persons were inoculated. Since I sent in my report 48 more have been inoculated. In Love Lane, 25 were inoculated, and since my report 43 more. In Chudda Chawl, 167 were inoculated, and on Sunday morning we inoculated 75 more. A case occurred, and the people came forward voluntarily to be inoculated. In Hyderali's Chawl, 86 were inoculated, and 14 have been inoculated since. In Contractor's Chawl, 50 were inoculated. In Jarawalla Chawl, 100 were inoculated. A case occurred there, and this morning 24 people came forward to be inoculated. The room in which the case occurred is now being disinfected, the patient has been sent to hospital. In the Telang property, at the time of sending in my report, 300 were inoculated, but more have been done since. The figures I have just given for the chawls make a grand total of 1035. With regard to this I may mention a very sad fact. Dr. Pithari has since died of plague. He was a gentleman who for many months quite gratuitously devoted his time to the discovery of plague cases. He performed a very large number of inoculations, but unfortunately he did not inoculate himself. He got the pneumonic form of plague. He was taken ill on Sunday, and on Wednesday he was dead, poor fellow. It is very sad.

17,879. You have had, I suppose, a favourable opportunity of observing what has happened to these people who have been inoculated?—I have.

17,880. Have you noticed any case of plague amongst them?—Only one. That was the case of a man who died on the 26th of last month. He was inoculated in September last. That is the only person who has come under my notice as having died.

17,881. Have any cases come to your notice in which uninoculated people residing in the same house with inoculated persons had plague, while the inoculated persons have escaped?—Yes, there was a case this morning.

17,882. Will you state it?—It happened in Jarawalla Chawl. A woman got plague, but the other people who were inoculated did not get it.

17,883. Could you give us the number?—It was only a question of three or four in that one room.

17,884. They have escaped so far?—They have.

17,885. Were you able to ascertain how the woman got plague?—No.

17,886. During the course of the operations you have engaged in, have you resorted to corpse inspection?—No, and I should not approve of it. It would be so objectionable to all the people, particularly Muhammadans, that I should not think it would be advisable to press it. I think the present mode of finding out deaths is all that is necessary.

17,887. From your experience, do you think that corpse inspection would assist materially in finding out plague cases?—I do not think it would. If I might express an opinion, I think that dealing with plague, in a large city like Bombay, is like ploughing the sand. One can, after all, only do one's very best, and trust to Providence for the result. That is my experience. It is possible that more actual plague cases would be identified, but I think the effect upon the people would be very objectionable. It would have a very disturbing effect. The quieter you keep the people the better.

17,888. Have you formed any opinion as to the relative malignity of the three outbreaks in Bombay?—The present outbreak is in many cases of a most virulent type. I have known two or three cases in which the people have come home from their work in the evening and have been dead by the morning. There is a great deal of pneumonic type; but I ascribe a great deal of it to the excessively cold weather we have had, and its long continuance, and the different conditions under which many people live. In my own immediate district, where I will not allow obstructions to be made to the free ventilation of air through the rooms in which the people sleep, I insist upon the place being kept open. I think that has something to do with the virulence of the attack, as far as the pneumonic form is concerned. I am not a medical man, and I speak with diffidence upon the subject; but I do think that the excessively cold weather we have had, and the different conditions under which the people live, have led them to get this pneumonic type of plague.

17,889. Have you noticed any instance in which people in the same house have suffered, one from bubonic and another from pneumonic plague?—Yes. In the Telang property we had cases of both. In Dr. Pithari's case he had both; he had the pneumonic form, and buboes as well.

17,890. Have you, in the Telang property, observed any instance in which a person has apparently caught pneumonic plague plague from a case of bubonic plague, or *vice versâ*?—That I could not say.

17,891. Can you give us any facts which will show the connection of rats with the diffusion of plague?—No, I do not know that I can, except that in Hyderali's Chawl a number of rats died, and we took the precaution of getting the people to take all their belongings out into the compound, or on to the verandahs and other places while we disinfected every room. I consider in that way we prevented a large recrudescence of the plague. We have had one or two cases, but very few; otherwise one might have expected a great many, for there is no doubt that rats do convey the contagion, because where there is contagion dead rats are frequently found. Where we have had a case of death from plague, and

we turned out the people's belongings, their old rags, and pots and kettles, of which they accumulate a very large number, we have frequently found sick and dead rats.

17,892. (*Mr. Cumine.*) Do you know of any case where a certain number of people have been inoculated, and a certain number uninoculated, and an inoculated person has been attacked and the uninoculated persons have escaped?—In the Khudda Chawl a man died last month who had been inoculated, but the other people who had not been inoculated also got the plague.

17,893. Then you do not know of a case?—No.

17,894. When you disinfect a room, do you disinfect it only once, or do you keep on doing it for a week?—In a fatal or a very bad case of plague, we disinfect the room for seven consecutive days.

17,895. That is what Mr. Firth does?—Yes. Those are the orders, which we carry out.

Mr. G. Lund.

14 Feb. 1899.

17,896. (*The President.*) What is the present method of the notification of the causes of death?—We get notices from the police; they give notice to our office.

17,897. How do they obtain the information?—It is information received.

17,898. It does not come through any medical source?—It does sometimes, but not always. If a medical man has a case of plague he notifies it to us or the district in which it occurs.

17,899. In the majority of cases the information comes direct from the police?—We discover a great many cases ourselves; on the other had, we get information of a good many cases from the police as well; sometimes more from one source, and sometimes more from another.

(Witness withdrew.)

Mr. N. N. KATRAK called and examined.

Mr. N. N. Katrak.

17,900. (*The President.*) You are Licentiate of Medicine and Surgery of the Bombay University and a member of the Municipal Corporation?—Yes.

17,901. You have watched the progress of plague in Bombay for some time?—Yes.

17,902. Since the first epidemic?—Yes.

17,903. And you have also watched the effects of treatment and prevention?—Yes.

17,904. You have observed the influence of the prophylactic fluid on the spread of plague, have you not?—Yes.

17,905. Have you any statistics to give us upon that subject?—I have statistics so far as the cases I have inoculated are concerned, but my conclusions have been formed more from the statistics which are laid before the public and it is that which has led me to come to the conclusion that inoculation is a good prophylactic and preventive against plague.

17,906. The conjoint evidence?—Yes.

17,907. How far does your own evidence lead you to that conclusion?—I have inoculated about 500 people, and all these cases have escaped plague except one, who developed plague symptoms within one hour after the inoculation.

17,908. Have you seen any bad effects following inoculation?—None in the 500 which I have done, and I have carefully inquired into the whole matter. So far as my inquiries go I do not think there is much truth in the complaints made from time to time. I should like to say that when we in Bombay read about the evidence of Dr. Lawrie and Dr. Johnston that the plague prophylactic was a putrescent fluid, as I had taken the great interest in the matter, and as I had found no unpleasant effects in any of my cases, I thought there must be some misunderstanding on the point. With that view I opened a certain number of bottles and re-sealed them with a view of seeing if exposure to the atmosphere had an influence in making the liquid putrescent.

17,909. How long did you leave them unclosed?—About 20 minutes. I could give the results of the examinations made by Prof. Haffkine, Dr. Milne, and Dr. Rau.

17,910. Those bottles which you refer to were examined by bacteriologists?—Yes. The results were that two whole bottles which were never opened were found to be sterile. In one bottle which I have mentioned the seal was not intact, and I had some doubt about its purity, and therefore I did not use it for a long time; it was kept in a corner. When Dr. Lawrie's evidence came before us I forwarded that bottle to Dr. Rau, and even that suspicious bottle was found to be sterile. Of the bottles which were opened by me and re-sealed, only two were found to be contaminated, but in one of these the sealing or the re-sealing was unsatisfactory to me, because the cork re-bounded and the seal was again broken. I made a note in that connection even before the bottles were sent to Dr. Rau, that the sealing was not satisfactory. With regard to the other contaminated bottle described by Dr. Milne, I did not take notes, because I had no idea of bringing the matter before the Commission. I have a dozen bottles which have been opened and re-sealed which the Commission can see if they wish.

17,911. Have you examined their contents?—No. They have simply been opened and re-sealed with the dates, numbers and so on marked on them. I have brought them for the use of the Commission.

17,912. Have you seen any good effects outside of the influence of the prophylactic upon plague?—Yes, I have particulars of some cases. The first case was that of a Parsee boy aged 15. He was inoculated during the second epidemic, and a few days afterwards he got plague. He was inoculated with a third of the dose because he wanted to go through three inoculations. He recovered of the plague and since then he felt a sense of chilliness for nearly 6 months or perhaps more. Then he got one inoculation. After that inoculation the sense of chilliness disappeared. After his first inoculation he got plague; he then passed that epidemic and the intervening portion, and during the last recrudescence he got himself inoculated again. Since then that sense of chilliness has disappeared.

17,913. What do you infer from that?—This is one instance in which it has done some good.

17,914. Are you quite sure that the first inoculation did not produce the sense of chilliness which you refer to?—After the first inoculation he went through the whole course of the plague, and a very severe one too.

17,915. That first inoculation might have been the cause of the chilliness?—It is for you to draw conclusions: these are the facts.

17,916. Have you any other facts?—Yes. There was a lady aged about 46 who had a sort of chronic fever lasting for many years This chilliness she got rid of after the first inoculation which was done on the 8th October 1898. Then I have another case of a young man aged 30 who had severe lumbago and a severe pain in the sacral joint. He was treated with blisters and applications, and was relieved temporarily from time to time. He was inoculated during the second epidemic and since that time he is free from the pain. This year he came to me to be inoculated, not as a preventive against plague, but as a preventive against the disease, which he believed would start in this cold season. He got inoculated on the 28th October, and he is still free from pain.

17,917. You have further cases of a similar nature?—Yes.

17,918. You have paid a good deal of attention, as a member of the Corporation, to the measures to be adopted during epidemics of plague?—Yes.

17,919. To what extent do you think insanitary conditions are accountable for the virulence or extension of plague?—My idea about the insanitary condition is that when a person gets the infection he succumbs to it more easily if he is exposed to insanitary conditions. If the sanitary conditions round about him are of a healthy nature, then the percentage of succumbing would be less and perhaps the virulence would be less also. I base my opinion first of all on the observations that I have made and which anybody can make, and also on some experiments made by Alessi which I have quoted in my précis.

17,920. Will you give us the quotation which you refer to?—He took a certain number of animals and put them in a cage and had the cage connected with the drain pipe. Other control animals were placed in

Mr. N. N. Katrak.

14 Feb. 1899.

ordinary conditions. After exposing them a certain time to the influence of the sewer gas the animals were inoculated with pathogenic germs as well as the control animals, with the result that a greater number of those who were exposed to the influence of the sewer gas succumbed. In fact, they first of all got the disease and succumbed in a large number, whereas those other control animals who were not under the influence of sewer gas succumbed in a smaller number, and also had a lower mortality.

17,921. You would include the removal of insanitary conditions among the measures which are the most important?—Yes, of the greatest importance.

17,922. Have you any experience with regard to disinfection in connection with plague?—I have, in my capacity as an official visitor.

17,923. What is the result of your experience?—My idea is that disinfection is possible, and also very efficacious.

17,924. You think it should be included among the measures?—Certainly.

17,925. With regard to the propagation of the disease, what do you find is the influence of rats?—Men as well as rats propagate the disease, but man is a much less important factor in that respect than rats. My observations are that a man cannot communicate the disease to the healthy if he comes in contact with them unless his discharges touch the mucous membrane or a cracked skin. But he can infect locality. How he does it, of course, I am not in a position to say, but my idea is that a plague-infected person, if he goes to a healthy place, infects that locality, and in some way or another, which I am not in a position to state, the disease is communicated to the rats. It may be that the discharge of this infected person soils the ground, or soils some eatables which the rats consume and they thereby get infected. However, this is a point upon which I can give no information. Having done this, the germs seem to get some increase in virulence, and the rodents, by their discharges, scatter the germs of plague broadcast. Practically man as a propagator to another man is a less important factor than rats. Another reason which I give in support of this evidence is that in hospitals where we find that a large number of patients suffering from this disease are congregated, where their discharges are removed from one place to another properly, the inmates, the surgeons, and even the people kept under observation are not affected, and if they are affected I have not been able to see whether the infection was got from the hospital or from their own houses. It is possible the hospital building might become infected just as much as any other house, and I believe a similar thing must have occurred in one of the hospitals of Bombay; I think it was the Mahratta Hospital—where a number of people got the plague. But, however, this is a surmise, and the full details of these incidents are not before me. But I say that a Hospital is as liable to infection as any other house; but the large number of disinfectants used, the intelligent care with which the discharges are handled and the great care taken to see that nothing eatable is thrown into the wards and places where the people live, are good safeguards against the infection of the dwelling itself.

17,926. Have you any instances in which it is clear that rats have actually infected a human being, and where you can exclude human conveyance distinctly?—Yes, if we can rely upon the history given by patients. I have two cases in which the history was something to this effect. A rat was found in one of the rooms. The patient, before she got the infection, took the rat and threw it out, and then with plain water she scrubbed the ground with her hands. In about 6 or 8 hours she felt a sense of chilliness, then fever began, and she went through the whole course and died.

17,927. How do you exclude contact with a plague patient?—There was no plague case at the time.

17,928. Was that in this city?—Yes, in Bombay.

17,929. Was there any plague in Bombay at that time?—Yes.

17,930. But there was no plague in the same house?—That is so.

17,931. What about the houses in the neighbourhood?—The neighbourhood was infected.

17,932. Have you any other case?—A Hamal is reported to have removed two or three dead rats from the house. After that he got a sense of chilliness and went through the whole course. The information was that he had a sense of chilliness within five minutes but, as I say, this case was only reported to me; it is second-hand evidence, and I could not give it with the same confidence as I gave the last.

17,933. What is your view with regard to segregating the sick?—I find that the segregation of the sick is not of so great importance as the segregation of the healthy, because the sick person himself is not likely to communicate the disease to the healthy. He may remain in the house if the house is well ventilated or in a sanitary condition, that is such a house where not only plague patients but any patients may stand a chance of recovery. He has to be removed from the house not because he himself is a dangerous person, but because he remains in the house and therefore other healthy people ought to remain in the house. But since the discovery of Prof. Haffkine's prophylactic I am strongly of opinion that in a large majority of cases plague patients may safely be allowed to remain in the houses and be treated by inoculated persons. Thereby we could reduce the mortality of the plague, because in spite of three years' bitter experience the people still have a dread of hospital, though it is unfounded, and the effect of the nerves or mental condition upon the course of the disease may easily be judged by those of us who are medical men. So if it is decided to treat the patient in sanitary houses with the condition that those who treat the patient must be inoculated, I think the percentage of plague mortality would be reduced, I will not say considerably, but to some extent.

17,934. Have you treated a large number of cases yourself?—No. During the first epidemic I treated about 17 cases, but since then all the plague cases are hospital cases and the medical practitioners do not get opportunities of treating them. We treat them in the beginning until they are declared to be plague, and then they are sent into the hospital. In the first epidemic I treated 17 cases of whom 12 recovered and five died.

17,935. In the first epidemic did you encounter many cases of the pneumonic form of disease?—No. Before the death of Dr. Manser I do not think the pneumonic form was recognised.

17,936. It might have occurred?—Yes. I have a recollection that one case which recovered under me had pneumonia as well as a bubo, but at that time pneumonic cases were not thought of.

(Witness withdrew.)

Mr. J. McDonald.

Mr. James McDonald called and examined.

17,937. (*The President.*) You are Headmaster of the Scottish High Schools, Byculla?—Yes, the Bombay Scottish Education Society's Schools. I should like to say I am in no way a professional medical man, but I shall be very glad to answer any questions.

17,938. (*Mr. Cumine.*) You are a non-official?—Yes.

17,939. You are not put forward by Government as a witness?—I am not. The Surgeon-General wrote to me, that is all.

17,940. How many years have you lived in Byculla?—Upwards of 32 years.

17,941. When the plague broke out did you take charge of the district?—I took charge of a section. The section is so named, but it runs from the Byculla Bridge to Kala Chowki.

17,942. How long have you been in charge of that section?—Since the beginning of plague till the present time.

17,943. Have you found in your section any overlapping of different departments?—I found great difficulty from the overlapping of the Health Department and the Engineering. Later on, Plague Officials increased the

difficulty, for the three departments were not unfrequently found to be engaged in the same inquiries. The Police sometimes made a fourth difficulty, when getting statistics on their own account.

17,944. What are the principal classes of people in your section?—Mostly a low class, either Mochis (shoemakers), Mahars, or workers in the mills.

17,945. What was it which specially enabled you to get a hold on the good-will of the majority of the people?—Firstly, they knew that I lived in the neighbourhood, and had some little position there. Then I was obliged to use a little money to help the poor—not the plague-stricken, but the poor—because there was much destitution in the place. Then I got some funds from Dr. Weir, and also 100 rupees from Sir James Campbell's Plague Committee.

17,946. When you got this money did you experience any difficulty in getting timely information of plague cases?—No; I should say that when I was informed about plague cases I went quietly and sympathetically to the people, and gave them advice quietly. Then, of course, I assisted them in any way I could, sometimes writing five, six, and seven letters in the morning to employers of labour to get employment for those who wanted it.

17,947. Do you think from this way of treating people that the number of cases in your section was probably less or greater than in other parts of the town?—I think considerably less, because they came with timely notice, and, when necessary, I helped them to remove the patients quietly, and they had no fear that there would be any rough treatment.

17,948. In spite of your conciliatory treatment there was a certain number of cases of concealment, I think?—There was, and is; there has been all along.

17,949. Would you attribute the greater part of these cases of concealment to intention or ignorance?—To ignorance, and the hope that it might not be plague, and so removal would be saved.

17,950. When a person had been removed to hospital, did you find it had a good effect to go to the hospital yourself afterwards and see him?—An exceedingly good effect. I know that those who recovered consider that their recovery was due to my having spoken for them to the doctors and nurses, rather than to the great care both doctors and nurses took of them. They believe that, although I had very little to do with it, and told them so.

17,951. Did you find that the nature of the carriage in which the people were removed to hospital had anything to do with their unwillingness to go?—Yes, often.

17,952. What would they have preferred, do you think?—I think they would have preferred a hand-carriage, that is to say, a species of dooli. They do not like to be wheeled through the town in a lying position; they would prefer a light hand-dooli with some covering over it.

17,953. Did you find that the system of having house-to-house visitation by native gentlemen was a permanent success up to the very end?—No, I did not.

17,954. What was your experience?—My experience was that at the beginning the attendance of native gentlemen was pretty fair, but I found as we got a little further on that cases cropped up in which these gentlemen allowed their feelings to get the better of their reason. They did not wish to hurt the feelings of their caste men especially, and they complained that a patient was sent to hospital under the name of some other person. The great object was to get the name of the sender put down as having sent the man to the hospital.

17,955. Did it come under your observation that the plague took any particular line in going across the town?—Yes; it was brought to my knowledge at a very early period. I have for years been observant of sickness in the town, firstly, from a conversation I had many years ago with Mr. Tomlinson, the water engineer here, who assured me positively that if care was not taken, and if the town was not drained properly of the great quantity of water which was being let in and deposited in the soil, and if waste of that water was not prevented, some serious evil would follow. Talking this matter over with Colonel Weir, he called my attention to the line from Mandvi to the Market, and from the Market on through the wards, going gradually northwards. Noticing it was actually taking the line which Dr. Weir had pointed out to me, I said to the people of my section—they are on one side of the railway—"It is coming along that line, and without doubt, "if you are not careful to prevent people from the "other side coming round here, they will come round "here, because they know we are quiet here, and you "will have the plague at such and such a time." And they did have it.

17,956. What is the connection between that line and the subsoil?—The flow of the subsoil water is north-west, in the direction of Worli, and then it turns round to the east and north-east, and in this direction plague goes gradually round. It has done it for these three years. It is pretty heavy to the west of the section, and now is coming right into this section.

17,957. I suppose you got some credit from the people for that?—Yes, especially because I did not tell them whence my information was. Had I told them, they would not have believed it. I am supposed to be a great doctor, although I do not profess to know anything about it. They speak of me as the Bara-Doctor-Sahib.

17,958. From what you have seen of disinfection you think, I understand, that one very important point is the goodness of the material supplied?—I think so, if it is to be of any use. I am not a great believer in disinfection.

17,959. You have something to say with regard to quicklime, I think?—Yes. In some cases they used quicklime, and the lime was certainly anything but quick in many cases, because I tested it when it was brought to disinfect the houses, and complained about it once or twice.

17,960. Do you also attach great importance to keeping the same plague officers in a ward throughout as far as possible?—Yes, very much so. I know that it could not be helped, but the change of plague officers certainly tended to disarrange many things. I had the good fortune to be always in the same section. As I was practically independent, they let me alone, and did not interfere with me in any way.

17,961. Was one of your chief reasons for thinking that European officers should be kept in one ward as long as possible, that then the superior officers know their subordinates, and can prevent them from doing any acts of oppression or extortion?—Yes. I thought in the case of Mr. Stewart, for example, that he knew the men intimately, and was able, when a complaint was made, to use his discretion to more advantage.

17,962. Have you any reason for supposing that the barbers are rather dangerous people in plague?—Yes. I am afraid that they still use razors to cut the buboes, especially about the neck. I have seen them in the neck, I have seen them in the chest, and I have seen them in the groin. I have mentioned in my précis one case which came under my notice at a very early date, but, strange to say, I have had several accounts of cases since which have taken place. I make it a point now, whenever I meet a barber, to caution him not to interfere with any buboes. Many of these barbers are of the species of the old leech, and profess to cure in this way, but I think it is dangerous.

17,963. Have you anything to say with regard to inoculation?—I was inoculated myself, together with my wife, son, daughter, and 14 servants. We were, I think, among the first 50 cases which Prof. Haffkine inoculated. I was a believer in inoculation, I am a believer in it. Two or three things have come under my own observation which perhaps are worth knowing. I have a son who is a medical man in the Army. He was up in the front and was invalided for three months; he took three months sick leave owing to his having very severe fever, and came down here, but could in no way get rid of it. At the end of three months he was obliged to return to duty, and was sent up to Baroda to the 8th Regiment, where plague had broken out. My wife advised him to be inoculated, and he had a desire to be inoculated, but thought that it might increase his fever. However, when he went up there, before he could advise others to be inoculated, he preferred to be inoculated himself, and from that date to this he has had no return whatever of fever. The same happened to his servant. I have also a young man in my house to whom the same thing happened, and there is a case which I know of, of a native who was of a very poor habit indeed, and had asthma for several years. He thought he was dying, but he was

Mr. J. McDonald.

14 Feb. 1899.

inoculated, and from that time to this he has recovered so much, that he is now thoroughly stout and has had no return of the asthma till within the last two or three days. The gentleman, whose clerk he was, told him that he wished the other clerks to be inoculated, and asked him about the facts. The clerk told him, "You "see now I am a strong man, but within the last three "days I have had something like a return of asthma, "and I am going to be inoculated again." I think it is not an uncommon idea amongst the people that inoculation either affects them very badly, or that they are likely to recover from fevers if they are inoculated. I think there is something with regard to the effect on fever from what has come under my own experience.

17,964. (*The President.*) That is malarial fever, I suppose?—I presume so.

17,965. (*Mr. Cumine.*) How long ago was the clerk inoculated?—Twelve months ago.

17,966. All this is within your own knowledge?—Yes, he is a clerk of Mr. Vilhaldas Damodhar.

17,967. (*Mr. Hewett.*) Have you any system of corpse inspection?—Oh, yes, they allowed me to do it very freely. I do not insist upon it in any way, but they ask me to do it. I ask them if there are any buboes, and they invariably say, "Come and look," and if I am doubtful about it I do go. I have no difficulty about it, but I think they will object in most cases, and especially would they object to young men examining.

17,968. Do you think that a Hindu would like to have his body examined by a Muhammadan or *vice versâ*?—No, I do not think so. My experience is that they are quite willing that a European should do it, but they do not like dark persons to examine them if they are of another faith.

17,969. Do you think that Muhammadans would resent the examination of female bodies?—I think they might, but they have not.

17,970. With you it is a different thing?—I have no difficulty, but I think they might resent it. The fact is they will resent it in the case of young doctors—they resent the examination of women by them when they are well. I have known of such cases, but I have not found any objection personally. I make myself very familiar with the people. I do not know whether you have seen the printed Marhatti letter of mine to the people. That sort of thing I usually read to them, or get somebody to read to them. They gladly listen to a thing like that. They also prefer that one should hear their story, even if they do not get what they want. I think it is most important that they should be heard, even if one does not agree to give them what they want.

(Witness withdrew.)

Mr. A. B. Davur.

Mr. A. B. Davur called and examined.

17,971. (*Mr. Cumine.*) Are you stone deaf?—Yes.

17,972. Have you any medical qualifications?—I have practised medical electricity for three or four years.

17,973. Have you any degree?—No.

17,974. You have volunteered as a witness, I believe?—Yes.

17,975. Have you treated any plague cases?—No, on account of the strict plague measures.

17,976. You mention in your paper a certain treatment for plague patients; has that treatment ever been applied in practice?—No.

17,977. Have you any personal experience of the results of inoculation?—I have acquired personal experience by way of observation, asking patients, and so on.

17,978. How many cases have you observed?—I was in Arthur Road Hospital one day and examined some patients there.

17,979. You mention in your paper, in speaking of the infective power of rats, that there is a worm of a certain kind in their interior which helps to spread the germ; do you know as a fact that this worm exists?—Only from natural history.

17,980. As you are deaf, perhaps you would like your paper to go in in its entirety as your evidence?—Yes.

"The following causes may be attributed to the origin of the different outbreaks of the plague:—

"*Firstly.*—In a hot country like India, when the summer is very severe and intolerable for two or three years, the soils bring forth very noxious and unwholesome exhalations of a fermentation (*i.e.*, bacterial) nature, just after the abrupt and continuous occurrence of heavy showers of rain for a considerable time. This is a natural cause or a phenomenon.

"*Secondly.*—Again, in a hot country like India, the wholesale merchants, brokers, and dealers in corn and grain, during a year of plenty when the crop is good, make large purchases of different sorts of grains with a view to make a good bargain in future when there is a famine or scarcity of grains. Now, if such large quantities of grain be not sold away in due time on account of the want of good demand they get damaged, and hence become unwholesome and unfit as an article of food. Grains, when hoarded up and kept for a considerable time without being used, produce a very noxious exhalation, a very bad stench which really affects the whole atmosphere of those localities where they are kept; and hence a great mortality of rats during those seasons.

"*Thirdly.*—A very imprudent and erroneous step was taken by the Bombay Municipality in respect with the drainage system, in the year 1893 or 1894, two or three years before the plague first broke out in Bombay, which has ever since produced a very bad effect upon the health of this city; and it is (*a*) the annexation of private or proprietary privies or closets with public gutters; and the other (*b*) is the erection of too many public urinals, which is no better than a mere nuisance. These can be regarded as creative causes.

"I should, therefore, in order to prevent the contagion of the epidemic from any further propagation, like to suggest a word or two about large and small quantities of corn and grain which are kept in stock, that a thorough inspection of all the godowns, store-rooms, and other places where they are kept should be made for at least once or twice a month, and that all damaged and noxious grains should be caused to be destroyed by fire: and the sacks, bags, and other containers ought to be either burned or thoroughly disinfected by boiling them in hot water.

"*About Disinfection.*—The present method of cleansing the houses where dead rats are found, as well as cases of the plague have occurred, with water, phenyle, and other disinfectants, is not good at all in this present situation. They ought to be either destroyed by fire, if possible, or cleansed with very hot sand or ashes, or, after removing some movables (which should be thoroughly disinfected and exposed in the sun for a few days) petroleum oil should be poured upon the ground and walls, and, afterwards, spreading hay upon the ground, they should be burned, provided that proper precautions are taken against fire already. But care should be taken that no water should be used at that time. Of course, the houses should be whitewashed afterwards.

"*About the Manner in which the Disease is communicated.*—The contagion of the plague is communicated through the skin. The plague microbes first make their abode in the corners of the eyes and nostrils, as well as in the middle ears, and from thence they get into the elementary canal through the eustachian tube and the jugular nerves. And afterwards they get into the regions of the chest and the stomach. Sometimes they easily enter the skin through scratches made into the nostrils with points of scissors while clipping the hair therein, or upon the membrana tympani and meatus auditorius internus while pricking the ears. Sometimes they (*i.e.*, the microbes) enter the eyes of other persons (*i.e.*, sound) or of those who attend upon the patients, before whom they (*i.e.*, the patients) either sneeze, cough, or upon whose faces they sometimes spit in a fit of temper. Or they enter through the cuts on heels of those poorer classes of people who go barefooted, who may happen to pass across some place upon some footpaths where some patients might have vomited or made water beforehand. The disease may be communicated by coming in close contact with the bodies of the patients or by putting on their clothes

through mistake. It may also be communicated by way of cohabitation, provided that neither of the parties is professionally a bad character. It can also be communicated by means of hair and shaving brushes and the aprons of barbers, or through some commercial articles, public conveyances, or through the dirty dresses of hawkers in household requisites.

"*About the Effects of Preventive Inoculation.*—As to the effects of preventive inoculation, it can be highly recommended, but not without caution. For there are some objections for it which ought to be very carefully remembered.

"The following can be regarded as some of them:—

1*st.*—The strength, manner (of injecting it into the proper parts of the body), and the number of doses of the serum.

2*nd.*—The general health and the physical condition of the persons to be inoculated.

3*rd.*—The climate and the general physical condition of the cities and villages in which they live.

4*th.*—The rules and sentiments of the people as well as their manner and mode of living.

"The following are some of the general observations upon effects of the serum. It causes fever and pain; the former leaves the persons of itself after a few hours and the latter may be tolerated to a great extent by a purgative if taken a day previous to inoculation. Buboes sometimes appear, generally in the left arm-pit, and very seldom in a groin (right).

"Its effects upon some persons (*i.e.*, those who live in villages as well as in large and comfortable bungalows or houses, with sufficient air and light, and on good food and pure water) are somewhat lasting for about two or a little more than two years; whereas in some persons (*i.e.*, those who live with a number of families in houses, situate in a very thickly-populated city and upon very poor food and bad water) are more temporary.

"The effects of inoculation upon such persons as the following are very good and salutary:—Persons suffering from, or labouring under, some mental disorder, nervous debility, nervous prostration, rheumatism, neuralgia, paralysis, gout, tumours and other morbid growths, hysteria, disease and disorder of the spina cord, scurvy, leprosy, scrofula and other chronic diseases of an infectious nature.

"But the effects of inoculation upon some persons as the following are generally bad, and sometimes they prove even to be fatal in case when such persons are attacked by their old diseases:—Persons suffering from, or labouring under, any disease or disorder of the kidneys, liver, bladder, stomach, lungs, the heart and other viscera and such other diseases which are easily subject to bronchial and catarrhal conditions.

"The following is a list of such persons who are generally free from the epidemic. Nevertheless they are subject to catching the contagion of the disease if in case they neglect to take due notice of any cuts, scratches, bleeding from the nose or gums, or from the fingers when the nails are badly pailed:

"Persons, whose temperature is at 99°, keeping thin yet always enjoying good health, having hot, much thick and red blood with smooth, bright and dry skin rather somewhat wrinkled; teetotalers not easily subject to catching cold, fever and so on; chaste, religious, and of refined habits not given to pleasures; not practising polygamy, of studious, sedentary and laborious occupations; dealers in oils, colours, lims; grogshop-keepers and their employees; mill hands and employees in gasworks, druggists and vendors of medicines, perfumers, tobacconists, mechanics, blacksmiths, and those who work before fire.

"Besides the above-mentioned, there are others who are entirely free from the epidemic:—these are the prostitutes, their paramours and visitors, professional bad characters, heavy drinkers, opium smokers and eaters, and the bhâng and gânjá smokers.

"There is one thing which is very remarkable and I am sure that it will indeed draw the attention of "Experts," which is this, that amongst all the population of Bombay, nay, even throughout all India, which represents a lot of peoples of various nationalities, castes, and creeds, there is not a single nation or a tribe like those of the Chinese and Japanese which is exempt from the terrible dread of the plague. For there is not a single case of the plague known as registered to have been occurred in either of these communities. Nevertheless, after a close observation and minute inquiry, it is not a difficult task at all to assign the cause to any particular thing or things. The causes, as far as I know, are these:—(*a.*) The peculiar formation and texture of their blood; (*b*) their snug and cleanly habits (though whatever may be said of their lives in their native places, but here they live a quite different life); (*c*) their habits of taking hot and weak tea now and then (for they never take cold water in its simple form in their life except fresh rain water); (*d*) they never take English, Native, or any other foreign medicines except those of their own countries; (*e*) and lastly, the thinness of their population in this country.

"*Difference between a False and a Genuine Case of the Plague.*—Seeing that much confusion and many blunders are made in finding out the genuineness of the plague cases on railway stations, detention and segregation camps, I should deem it to be proper to throw some light upon this piece of inquiry.

"The first and the most obvious symptoms of the disease are fever and buboes. The presence of fever and buboes is found in a false case of the plague as well as in a genuine one. But the fever is generally either of a remittent or of a simple nature; the latter is very common and can be easily caused by fatigue, hunger, hard work, want of good food and water or recreation or on account of some slight change in the weather or by fear or anxiety; and therefore it leaves the sufferers very soon and that without any remedy.

"As to the buboes in males, they appear on account of taking a long journey on foot, or fast or excessively running, or by climbing hills or precipitous places, or while wrestling in their athletic pursuit, or it may be a pure venereal case, or through some change in the weather, or on account of gonorrhœa or any other disease of the urinary organs which they may be suffering from.

"In females they (*i.e.*, the buboes) are sometimes of the venereal kind; or on account of their being very much taken up with their household works, or owing to their slender build or weak constitution.

"They are sometimes found on women labouring under pregnancy either a little before or after delivery. This is owing to their miscarriage or extreme weakness or debility or through the damp or moist atmosphere of their houses.

"As to the buboes which are found on children, they easily appear on account of their childish mischief, while playing at the hide-and-seek game or climbing some trees, jumping or by playing at marbles when if some nerves be straitened; or if they get some sudden shocks or sprains in their legs, or through some change in the weather.

"But these kinds of buboes can easily be distinguished from those of the genuine case according to their shape, size, and colour.

"As to the shape of the bubo (in a false case) it is somewhat of a round or circular form. Its size is a little more than a marble or sometimes nearly as large as that of a full grown almond. As to its colour it is somewhat of a white reddish one.

"As to the fever and buboes in a genuine case they are of the following nature:—The fever is of the typhus kind (please see my paper on the Plague). As to the bubo (in a genuine case) it is nothing but a mass of fatty substance somewhat of a yellowish colour like that of wax or cheese (when cut) rather hard in the beginning, but getting softer either when going on to putrefaction or under the influence of poultices, very sticky and of a bad stench. Its shape is somewhat of an elliptical or an oval one. As to its size it is from an ordinary to a full-grown mango stone, much thicker in the middle and very intolerably painful when putrid. The bubo appearing in the throat always proves to be the most obstinate and even fatal than those which are found in the armpits, stomach, and the groins; and hence there is little or no chance for the recovery of such patients. Its colour. It is slightly of an olive colour in the beginning, but of a darkish black when putrid.

"It will not be considered as improper or useless if a word or two be said about this piece of inquiry.

"*Plague Expressions.*—The complexion of the face is somewhat of a darkish colour. Eyes wide open. Eyelids thrown backwards. Enlargement of the pupils. Standing and walking postures not erect, but rather bent (though many an attempt made by the patient to walk erect in order to avoid suspicion); and extreme fear and anxiety.

Mr. A. B. Davur.
14 Feb. 1899.

"*New Suggestions for the Treatment of the Critical Cases of the Plague.*—It will not be amiss to throw a suggestion or two for treating plague patients in a very critical state when the hospital authorities do not find a single ray of hope for the recovery of such patients.

"1*st.*—First of all the region of the heart and the stomach and the intestines ought to be very thoroughly cleansed by means of a douche. Of course the preparation for this kind of douche must be of a bactericidal nature.

"2*nd.*—That hot and fresh blood of some vultures such as feed upon dead carcases of plague patients (especially those who died without any medical assistance) should be introduced directly into the bodies of the patients through an artery or a main nerve, at the same time keeping the chests of the patients rubbed either with cod-liver oil or oil of almonds in order to strengthen their hearts; but no strychnine or any other injection should be used at all.

"3*rd.*—That electric currents should be introduced right into their blood—of course at the same time keeping their hearts strengthened as already described above.

"*About Clinical Thermometers.* — That many an innocent patient becomes a victim of the diseases of some other patients through the instrumentality of the clinical thermometer on account of the germs of the diseases found, in the febrile moisture of the skin, sticking to it.

"Again one thing must be remembered very thoroughly, that the natives are in the habit of getting their armpits shaved by the barbers. Now arm-pits, like cheeks, are not flat parts of the body for an easy shaving. So it is probable that razor-cuts might be found therein.

"Therefore it can be remarked that it is absolutely necessary either to disinfect the thermometer or allow it to remain into some warm water for a few minutes especially after taking the temperature of any patients suffering from any infectious disease."

"*The Bubonic Plague.*

"I.—What is it?—It is a fever.

"II.—*Its Antiquity.*—The plague is of a very remote antiquity. It seems to have visited Egypt, Messopotamia, Asia Minor, Arabia, China, Persia, India, and some other parts of the globe, on different occasions, and in different forms ever since the times of the Pharaoes of Egypt, 1490 B.C., and the Shepherd Kings of the East and lately in Europe, especially England.

"III.—*Its Name.*—The proper name of the fever is Typhus (Gravior).

"IV.—*Its Nature.*—The fever is of a very putrid, contagious, and malignant nature. The temperature of the body of the patient is from 104 to 106 degrees, and the pulse beating very quickly and heavily.

"V.—*Its Causes.*—Among the most obvious causes which contribute to its contagion, the following may be enumerated—(*a*) Noxious exhalations from stagnant waters of the gutters; (*b*) slimy mud and rubbishes taken from the gutters and exposed upon the roads to be dried up by the sun; (*c*) corrupt, damaged, or noxious grains; (*d*) putrid fish, meat, fruit or such other eatables; (*e*) residence in confined situations where the atmosphere is unwholesome and the rooms not properly ventilated; (*f*) intemperance and immoral habits; (*g*) tropical or very hot climate, especially after a very heavy rain; (*h*) and the want of pure water and due cleanliness.

"VI.—*How it enters the Human Body.*—The contagion of the plague enters the human body through cutaneous lymphatics, and thence produces the disorder of the lymphatic glands.

"VII.—*Does the Plague make use of any Animal Agency for the Propagation of its Contagion?*—Yes, the rat, the fly, the gnat, and such other creatures have their share in conveying the miasms and other poisonous elements by means of microbes, bacteria, bacilli, protozoa, and so on.

"How does it do so? Its manner of working is thus:—According to my opinion, that there is a *worm* of a certain kind, lodged in the belly of rats of a certain kind (perhaps such as live in the fields and gutters). The worm in the belly of the rat either becomes ill, or dies away when the rat partakes of some putrid grain, meat or such things or inhales the noxious exhalations from the gutters; and thus the rat is infected with a poisonous fever. Now, men contract this poisonous fever in any of these ways: (*a*) that the rat, after entering the godowns, the shops or houses, makes some dirtiness there, and afterwards the fly, the gnat, and such things sit upon it, and then they sit again upon human bodies; (*b*) or through the bites of such infected rats; (*c*) through the application of the febrile moisture of their skins by their jumping upon or dashing against the human bodies while they are asleep; (*d*) or by hiding themselves into their clothes for the fear of cats; and thus men cause inflammations upon their own bodies by scrubbing it with their nails, which may, perhaps, afterwards take the form of buboes and such other tumours.

"VIII.—*Its Symptoms.*—Fatigue, extreme debility, unquenchable thirst or desire for thirst, uneasiness, appearance of buboes, carbuncles or other inflammations, extreme irritations in the arm-pits and the groins, extraordinary heat in the body and in the head, and so on.

"IX.—*Is the patient aware of his Situation when he is infected with the Epidemic?*—No, he comes to know of it two or three days after the setting in of the disease.

"X.—*Is the Plague communicable? If so, how?*—Yes, it is communicable. Not by association, but only by contact alone. For if proper precautions be taken, then other individuals living in one and the same house may be free from it.

"XI.—*How many Species of the Plague are there? And what are they?*—There are three species of the Plague. (*a*) In the first species the energy of the brain and the nervous system is greatly impaired, indicating by a certain kind of change in the speech of the patient, such as low drawling and interrupted utterance, the tongue is more or less white in the centre and at the extremity, countenance pale, strength much impaired, the anxiety great, and the stomach extremely irritable. Rigors and pain in the lower parts of the back are found. (*b*) In the second species the state of the brain is horribly excited, intense pain in the head, thirst frequently considerable, though sometimes wanting, countenance flushed, and utterance hurried, frequent, epistaxis, appearance of glandular swellings and their disappearance without making a slight change in the system, appearance of buboes in the arm-pits and groins (right). Carbuncles appear on different parts of the body, and they rapidly show some disposition to become gangrenous, although the patient is attacked by a high delirium and thus brought to the termination of life within two or three days. Sometimes he lingers on to the seventh day, but seldom the eighth or ninth day. (*c*) The third species is somewhat akin to the last one save the symptoms are much milder and the brain comparatively a little affected. The buboes and carbuncles go on rapidly yet mildly to suppuration. And if prompt and early precautions be taken, the patient recovers from the epidemic.

"XII.—*The Duration of the Disease.*—The exact duration of the disease is uncertain; for it is various. Sometimes the effect of the contagion results in the immediate extinction of life. Sometimes the patient survives but a few hours, sometimes he lingers on till the thirteenth, fourteenth, or even the seventeenth day of the disease.

"XIII.—*What Changes are observed to have been wrought in the Body of the Patient on the* post-mortem *Examination?*—The omentum, the stomach and the intestines gangrenous in some places, the liver in a state of congestion and considerably enlarged, and the gall bladder filled with a black fetid bile and the pericardium with a bloody fluid. Proofs of inflammation and gangrene are also observed in the brain and its investing membranes, in the lungs and in the kidneys. In many instances the glandular system has been found in a diseased state, the blood black and loose in its texture. On a minute search, one, two, or three microbes are found in gall bladder, pericardium or in the glandular system. These colonies of microbes belong to the plague-propagating class. The complexion of the face as well as that of the whole body appears to be of a light dark colour.

"*My Method of the Electrical Treatment for the Cure of the Bubonic Plague.*

"I.—Injections.

"II.—Mixture.

"III.—Electro-chemical bath.

"IV.—Chemical application of electricity.

"V.—Applications of cupping-glasses, ice, and oily frictions.

"VI.—The uses of sea-breeze and sea-bathing.

"I.—*Injections*—(*a.*) *Chlorine or Gaseous Injection.*—Take some sea-water, or, if not, take some ordinary drinking-water and add a little quantity of chloride of sodium into it and separate the elements from the water by introducing electric currents into it. The following process is being done. The oxygen gas which is in the water mixes with the chlorine (*i.e.*, a greenish-yellow gas produced from the salt), and thus chloride of sodium becomes hypo-chloride of sodium. The same is the preparation for the injection. (*b.*) Oily injection which is nothing but the pure oil of almonds.

"II.—*The Mixture.*—It is composed of sulphate of quinine, antipyrin and tincture of camphor.

"III.—*Electro-chemical Bath.*—The electro-chemical bath is administered in the following way: According to my theory for the present epidemic, the patient is placed up to his neck in a large metallic tub which is filled with iced or cold water, added to it a little quantity of hypochlorite of sodium [as per the injection marked (A)] together with some hydrochloric acid, and insulated from the ground. The patient sits in a tub upon a bench of wood or wicker-work insulated from the tub, and having the length of the body. The tub is to be connected with an electric battery by means of a copper or brass wire, and the patient holds one electrode in his hand. Afterwards the battery should be worked on.

"IV.—*Chemical Application of Electricity.*—An oval piece of brass of medium thickness (*i.e.*, $\frac{1}{20}$th of an inch) and about 4 inches in length and 2 inches in breadth should be taken. Then a piece of fine linen previously saturated with hypochlorite of sodium [as per injection (A)] is placed upon the tumours (*i.e.*, buboes or carbuncles, whether hard and dry, or soft and gangrenous), then the piece of brass be placed on the linen. Another piece of brass which is about 4 inches in length and an inch in breadth, having round corners, should be placed upon the belly of the patient near the abdomen like the first piece of brass. Then they should be connected with a battery which should be set to work.

"V.—*Applications of Cupping-glasses, Ice, and Oily Frictions.*—If the inflammation be not very severe and the pain tolerable, cupping-glasses with previous scarifications may be used with much advantage. For the nature must be assisted in the work of throwing off the morbid matter by the pores; because sometimes the emetics, the laxatives, the purgatives, and the sweating regimens are of no avail at all.

"*Application of Ice.*—In order to check the strength of fever, the intolerable thirst for water, and for the burning inflammations and irritations, the use of ice is absolutely necessary. It is applied to the crown of the head, held into mouth, arm-pits and groins. It should be used in their bathing-water too.

"*Application of Oily Friction.*—Perhaps it will sound very strange into the ears of some medical gentlemen that it is essential to make use of oily frictions in this epidemic. But if we look at the statistics of the deaths occurred by this epidemic we shall hardly find three, four or five persons out of 100, whose occupation is that of a dealer or worker in oils. Besides these, a little experience will teach us that it is a death, not only to microbes, insects, or flies, but even to worms, mice, and little birds too, if they are entangled into a small quantity of oil. For this purpose I recommend the use of the oil of almonds, because it has a soothing and healing property in itself.

"VI.—*The Uses of Sea-Breeze and Sea-Bathing.*—It is very essential that such patients should have the advantage of sea-breeze and sea-bathing. If such a thing be not practicable, then let a linen shirt and a trouser be dipped into sea-water and wrung off and then worn by the patients, wet and cold, allowing them to walk here and there in the ward. Let them have cold baths, two, twice a day.

"I should here like to make a request that an anatomical examination be made upon some rats in order to establish my theory, that there is a worm in the belly of some rats; that the true origin of the epidemic be found out.

"It will be found out, after a careful reading of this paper, that my electrical treatment for the bubonic fever, which I have laid before the public, is perfectly harmless and will prove to be an efficacious one, if a trial be given to it. Nevertheless, if any doctor or doctors entertain any doubt about its efficacy, I shall, however, request them to try it upon some lower animals by inoculating them with the matter taken from the buboes or carbuncles from any patient: and then try an experiment upon them according to the directions I have given. If the experiment proves to be successful, then let patients be treated accordingly. If not, we will leave the matter off.

"*N.B.*—The present is the true copy of my *Paper on the Bubonic Plague*, which I had written in the middle of the month of October 1896, when, or a little after, the plague first broke out in Bombay. It had been shown to some doctors and public men of established reputation, whose names I cannot give without their permission. But their names may be given with permission, if required. The manuscript copy may be produced, if desired."

(Witness withdrew.)

Mr L. Godinho called and examined.

17,981. (*The President.*) You are Deputy Health Officer here?—Yes.

17,982. Of what district?—At present I am at E Ward East.

17,983. (*Mr. Hewett.*) What are the means by which plague is communicated?—First by personal contact, secondly by kit, thirdly by rats, and fourthly by aërial infection.

17,984. When you speak of personal contact do you refer to the contact of a person who has bubonic plague or pneumonic plague, or both?—Both.

17,985. Can you explain how you think a person with bubonic plague communicates it by personal contact?—I have seen, especially among the poorer Hindu classes, females attending plague cases with buboes and nursing them. The females never wash their hands after nursing the sick, and they carry their spittle to their own noses or mouths.

17,986. Do you think that was through the sputum?—Yes, and the saliva.

17,987. Would not that point to the cases being pneumonic?—The cases were not pneumonic.

17,988. Have you any instance in which a person with bubonic plague gave pneumonic plague to another person?—Only one.

17,989. Will you specify it?—In Carpenter Street a medical man was treating plague cases which were all bubonic. He got fever and then showed symptoms of pneumonic plague. On the third day he developed a bubo. He had both forms of plague, pneumonic and bubonic.

17,990. Have you any instances in which a pneumonic patient gave bubonic plague to another person?—Yes; in the Mahratta Hospital a Resident Surgeon suffered from pneumonic plague. His nephew and another relative attended upon him. When they went back home the nephew suffered from plague and died.

17,991. Is that the only instance you have in that form of communication?—In this special instance several suffered. Altogether about eight persons suffered, and all died. They got it from the Resident Surgeon. Some had the bubonic form and some the pneumonic.

17,992. Do you think that funeral ceremonies tend to communicate it?—Yes.

17,993. Do you mean from the body or the clothes of the deceased?—I would classify those separately. So far as the Hindus are concerned they have got special ceremonies which the female kind conduct. First they make an ablution, and then afterwards put some stuff into their mouths, and noses, and other

Mr. L. Godinho.

14 Feb. 1899.

orifices. The Muhammadans close the different orifices by a plug of cotton, camphor, and spices. A rupee or some coin is placed in the mouth; afterwards this is taken off, and replaced, and I have seen the women-kind suffer from plague through handling these coins.

17,994. Can you give us any instances of infection from clothes?—Yes. I know one specific instance in which a Christian suffered from plague at Lanauli. A month afterwards his nephew used his blanket and got the plague and died.

17,995. Was there any plague at Lanauli at the time?—Yes. The nephew used the blanket he had in Bombay in a house in which there was no plague.

17,996. Have you any instances in which plague has been communicated through rats?—Yes. In the present epidemic, towards the end of February 1898, sick rats were found in Dukar Gali in Tanaswadi. They made their appearance on the ground floors at the east end of the Gali, and then rapidly travelled to the west end, keeping to the rear of the Galis, where water could be easily got. About a week after the appearance of sick rats the inhabitants of Dukar Gali began to sicken and die of plague. The first cases happened in houses where dead rats had been found. From Dukar Gali the rats travelled north-west to Burrow's Lane. A listless rat was found on the 5th March in No. 3 Burrow's Lane, and eight days after a servant boy, who is said to have killed and burnt a rat, was attacked with plague. I know that the boy did play with the rat and did burn it.

17,997. Do you know for a fact that the boy was not subject to any other source of infection?—Yes.

17,998. Was there no plague patient with whom he might have communicated?—No. The residents of this house were living then in a tent at Kennedy Sea Face.

17,999. Under observation?—No; he was a medical man, and had his own tent.

18,000. Why could not the boy have gone to some infected portion of Bombay, and there got plague?—The boy was in the tent, and used to go back to the house to sweep it, and he brought the news that he saw a sick rat there. The boy was in the tent all the while.

18,001. What security is there that the boy did not go to the town?—I cannot answer that.

18,002. I mean can you exclude all other possible means of infection?—I am almost certain the boy did not go anywhere else, because this refers to my own servant boy.

18,003. Have you had experience of mortality among rats before cases of plague occurred in human beings?—Yes, and also afterwards.

18,004. Have you observed mortality among rats to precede mortality among human beings, in any case except the one which you have just specified?—I have observed it in all the three epidemics.

18,005. That is to say you have observed mortality in rats in individual houses to precede attacks among human beings in those houses?—Yes.

18,006. I presume that when you made these observations plague was existing in the neighbourhood?—These were in different streets.

18,007. Has plague been present within a mile of those streets?—Within half a mile. I have seen rats sicken where the plague cases occurred only among men; first men suffered, and then on the eighth or tenth day rats began to sicken.

18,008. What do you wish to say about aërial infection?—I believe that in stuffy rooms, where a pneumonic patient is being treated, the air becomes infected and the nurses and other attendants suffer from plague afterwards.

18,009. Have there not been in Bombay some very marked instances in which, although there has been pneumonic plague, the attendants in the hospital and also the relatives of sick persons in the hospital have escaped entirely?—Quite so. I put that down to disinfection, and free ventilation in the hospitals. The perflation of the air reduces the infection to a minimum, and I believe also the attendants and medical men in the hospitals get immune against plague in a certain time in some way.

18,010. You say that in two instances the attendants on parsons suffering from pneumonic plague rapidly got the disease?—Yes.

18,011. Is it not possible that they got it from the sputum of the patient?—In these two instances I think not, because these people were in separate rooms; they did not occupy the same room. They did so many hours in the room, then went to the next room, and passed the time there. Of course it is just a remote possibility they *might* have got it from the sputum as they knew the value of disinfection.

18,012. Have you any experience with Yersin's curative serum?—I only know two cases which were treated by Dr. Yersin's serum sufficiently early; the results were negative.

18,013. Have you inoculated any persons?—Yes, about 400.

18,014. Have you observed the effects of inoculation?—Yes. The action depended upon the dose I gave.

18,015. Have these 400 persons remained under your observation after inoculation?—No, not all.

18,016. Therefore you are unable to see how far they have been attacked by plague?—Yes.

18,017. Have any instances come to your notice in which persons were inoculated and subsequently got plague?—Yes, a few. Dr. Davar suffered from plague in December 1896; he was inoculated a few months afterwards, and subsequently suffered from plague and died. Dr. Davar was a special officer working in the Kamatipura district.

18,018. Have you any other instances of persons who suffered twice from plague?—Yes. Mrs. Ezra suffered from plague at Hong Kong on the 24th July 1894, and on the 6th December 1896 she got a second attack in Bombay—Bellasis Road.

18,019. Did you attend her during the second attack?—Yes.

18,020. Did she recover?—Yes.

18,021. Have any other instances come to your notice?—Yes, one Narayan Mulji suffered from plague three times. I saw him the third time. The first time he was treated by Dr. Ismail Jan Mahomad.

18,022. When did you attend this Narayan Mulji?—In the second epidemic in July or August 1897.

18,023. What form of plague did he have?—Bubonic plague. The bubo was in the axilla accompanied with diffuse cellulitis.

18,024. Was that his second or third attack?—His third attack.

18,025. Will you give us the history he gave you?—He said he suffered first in 1896, when he had a bubo in the groin.

18,026. Who attended him then?—Dr. Ismail Jan Mahomad treated him the second time he had plague; that was in the second epidemic, about November.

18,027. Do you know who attended him the first time?—I do not know.

18,028. Did he recover from the third attack?—Yes. Then he was also treated by Dr. Ismail Jan Mahomad.

18,029. Is this man to be seen?—Yes, I think so.

18,030. Could you bring him here on the 20th?—I am sure he would be willing to come, because he offered himself, but I should like the Secretary to write to him; that might induce him to come. (Mr. Narayan Muljee was examined on February 20th.)

18,031. Have you any other cases of double attack?—Yes, a Customs' clerk suffered twice from the disease, the first time in November and the second time in April 1897.

18,032. Did you attend him on either occasion?—I saw him at the hospital; he was at the Lal Bag Hospital the second time.

18,033. Did he have bubonic plague both times?—The first time he mentioned to me that he had a bubo in the left groin. The second time I saw him, and the bubo suppurated, and he recovered.

18,034. Was the bubo in the same position?—I do not remember exactly.

18,035. Could you produce this man also?—I could not say that, but you could get the facts from Mr. Green, the Secretary of the Plague Committee. If you wrote to the Collector of the Customs you might get at that man. (The man in question, Mr. Champaklal Thakurdas, was subsequently examined on the 20th February).

18,036. Does that complete the list?—There are two more mentioned in my précis, but I am doubtful, because they might have been recurrences.

18,037. It is possible the disease was continued the whole time in one case?—I do not think so, because there was no rise of temperature, and the buboes had disappeared. It might have been a recurrence. I cannot say.

18,038. Have you observed any cases of mild form of plague?—Yes.

18,039. Can you describe the symptoms in these cases?—A man generally suffers from a small chill and headache in the front of the head; he then feels general *malaise*, pains all over the body and joints and small of the back. His temperature rises to about 100, and he is ill for a day or two and then he is again better.

18,040. Do these people go about their usual business while suffering in this manner?—Some do. There was a man named Mascarenhas, who lived at No. 18, Church Street. He had three days very slight fever, and on the fourth day a small shotty gland appeared; all the while he was all right, that is, he continued his work for three days, and on the fourth day the gland appeared, and on the fifth and sixth days his temperature was 100.

18,041. Did you attend him?—Yes; I showed this case to Colonel Wilkins.

18,042. When was that?—In October—the 6th to the 12th October 1898.

18,043. Can you tell us whether the cases with mild form of plague occurred mainly at the beginning, middle, or end of an epidemic?—Towards the end I saw people suffering from fever of a relapsing character, and then, afterwards, on the 14th or 15th day, they developed buboes; in one or two instances they died. On the other hand I have seen plague cases develop buboes on the third or fourth day, and then proceed towards recovery, and afterwards have the relapsing kind. It is a sort of mixture of the two. They had fever of the relapsing kind and a bubo appeared afterwards.

18,044. Have you observed this mild form occurring among young persons?—Young adults.

18,045. Not among children?—No; I have not seen them have it.

18,046. Do you think you could find any cases of it now?—Perhaps.

18,047. Will you try and find some cases?—Yes.

18,048. Do you think that inoculation is the chief means by which plague is caught?—Yes, through an abrasion or something of that kind.

18,049. Do you think that the practice of cleaning brass vessels with mud has anything to do with it?—From my observation in C Ward I found that in certain houses in the central street, Kumbarwada, the women suffered more from axillary bubos than men. Men suffered from femoral bubo.

18,050. The women are the persons engaged in cleaning the brass utensils?—Yes, in the mud-making operations.

Mr. L. Godinho.

14 Feb. 1899.

18,051. Do you think that explains the frequent occurrence of the axillary bubo among women?—Yes, I think so.

18,052. (*The President.*) Have you treated many cases yourself?—No. In the first epidemic I did treat a few.

18,053. Have you latterly seen many cases throughout the course of the illness?—Yes. During my tenure of office I must have removed over 1,000 to hospital. I have gone to hospital and seen them, but I have not treated them.

18,054. Were there many pneumonic cases among those you have seen?—Yes.

18,055. Have you observed in any case any swelling of the anterior part of the body?—I found dulness on percussion.

18,056. Did you see anything in the nature of œdema in the skin?—Yes, I could mention cases, and they had also bubo. For instance, Dr. Mehta, who attended the Banniah Hospital at Pinjgrapole, got plague, and had a diffuse swelling all over, anterior and posterior, so far as the lower angle of the scapula.

18,057. That is, on one side of the thorax?—Yes.

18,058. But have you seen anything like a general swelling of the whole of the anterior surface?—No. In cervical cases in children, where the buboes were in the neck, I have seen the swelling come down so far as the middle of the sternum.

18,059. In the cases of mild plague have you any instances in which they infected any other persons?—I could mention only one instance, but the second case in that instance, a woman, to my mind was not suffering from plague, but from fever. Mascarenhas had plague, I believe—he had a bubo in the right groin—and his mother suffered from slight fever which lasted three days.

18,060. She became affected afterwards?—Yes. Dr. Wilkins said the enlargement of the gland in Mascarenhas' case might have been due to other causes, but I could not find any abrasion, no cut, nothing on the foot, and I put that case down as one of mild plague.

18,061. The second case was fever?—Yes.

18,062. Then you have not seen any cases of mild plague infecting any other persons?—No, I have not.

18,063. (*Mr. Hewett.*) You have seen a good many of the people employed upon plague duty here?—Yes.

18,064. Have you noticed any of them with symptoms of plague, enlarged glands, or anything of that sort, without their actually getting plague?—Yes.

18,065. Is that common?—I think it is frequent among workers on the plague. Several times the glands get enlarged, especially the femoral glands, and then the enlargement passes away.

(Witness withdrew.)

Mr. A. H. Simcox, I.C.S., called and examined.

Mr. A. H. Simcox I.C.S.

18,066. (*The President.*) You are in the Indian Civil Service?—Yes.

18,067. You are Assistant Collector of the Malegaon sub-division of the Nasik district?—Yes. Malegaon is a large town of about 20,000 to 25,000 people. It also has another village which, although not included in the Municipal limits, is practically a part of the town: it is separated by a river which is nearly dry.

18,068. When did plague appear there?—The first known case was on the 11th November 1897. I do not think there was anything before that, because I traced the infection directly to an old woman who sneaked in from Bombay.

18,069. It was imported from Bombay?—Yes.

18,070. What measures did you adopt?—I was out in the districts. I got back the next day, and we took immediate steps. We got a large dharamsala for a hospital, and segregated the cases as they occurred. There were two other cases on the first day. The Municipal people suspected it on account of their having been three deaths very close together. The old woman died and two other people died at the same time in the same house. At that time there was only a native Hospital Assistant there, and I am sorry to say that I suspect he took bribes; we only got one or two declared cases a day at that time, all in the same neighbourhood. We began by clearing out the house in which a case occurred and the two houses on each side. After some time we built regular lines of huts for contacts and for the cases, for the people who nursed the patients and the contacts, and the people from the neighbouring houses. We got into regular swing, but never succeeded in stamping out the disease with this partial evacuation, which lasted from 12th November till the 19th January.

18,071. In that period how many plague cases occurred?—About 350.

18,072. You were not satisfied with the success of this measure?—No. On the 5th January we got 18 cases, our maximum for one day.

18,073. Besides this partial evacuation, did you disinfect the houses?—Yes, we disinfected all houses which were evacuated.

Mr. A. H. Simcox, I.C.S.

14 Feb. 1899.

18,074. When did you adopt complete evacuation?—On the 20th January I issued a notice that all the town was to turn out, in four quarters, allowing one week for each quarter, but it really came to three weeks, because towards the end the last two quarters went out together. They were all out on the 10th February. I got them into the maidan, about a mile from the town, where there was a dharamsala, a big rest-house for travellers, built of stone. I would not allow the people to go anywhere else but into certain lines. We made lines in the fields like a military camp, and gave each man so many square feet for building his own hut on, and made lanes between. We got the whole town out in this place. The population had largely diminished. A great many people ran away at first, but I reckoned I had about 12,000 people in the camp.

18,075. How many cases occurred after this complete evacuation on 10th February?—After that we had one or two cases. Almost all the population are weavers, and we put up the strongest huts we could to support their hand-looms, but we found we could not completely satisfy the people's requirements. They lived from hand to mouth by their daily weaving, and I had to select a certain number of large weaving shops in the town—not living houses—disinfect them, and let the people go into them in the day-time. There were a few cases of those people stealing into their houses at night, and it was among them we had further cases of plague. We did not have a single case which could be proved to originate in the health camp.

18,076. Do you know where the people who fled from the town went to?—Perfectly. I had a complete watch kept on all the country round, and I can practically tell you where every man went to. None of them went far away.

18,077. Did they convey the infection to anybody else?—No, not a single village was infected.

18,078. That disposes of the 25,000 people, does it not?—Yes. Each village in this country has a large area of fields belonging to it, and by far the greater number of people were within Malegaon boundaries.

18,079. How long were the people kept out?—We let them in again on the 2nd April.

18,080. Previously to that, what had you done to the evacuated houses?—I had disinfected every house all through the town, the greater portion with perchloride solution, according to Government orders. There was a man in the town who wanted to get rid of a lot of sulphuric acid, so I wrote to Dr. Hay, and got the opinion of the Surgeon-General that sulphuric acid, 1 in 500, would do instead of perchloride. Then I bought some sulphuric acid and did a certain number of the houses with that. We have not had a case since. The people have gone back, and there has been no recrudescence.

18,081. Are you free now?—Yes.

18,082. What was the effective measure which you adopted, in your opinion?—Turning out the town. Towards the end of our partial evacuations we turned out the whole block in which there was a case. Some people were bound to get into the neighbouring houses where they had relations. We found a great many dead and dying rats also.

18,083. Partial evacuation did not succeed?—No.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

FORTY-EIGHTH DAY.

Wednesday, 15th February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Lieut.-Col. W. G. H. Henderson, I.M.S.

15 Feb. 1899.

Lieut.-Col. W. G. H. HENDERSON, I.M.S., called and examined.

18,084. (*The President.*) You are in the Indian Medical Service?—Yes.

18,085. You are prepared to give evidence on the outbreak of plague in Hyderabad, Sind?—Yes.

18,086. (*Mr. Hewett.*) When did the first imported cases occur in Hyderabad?—The first imported cases occurred in Hyderabad in the first week of January 1897, shortly after the appearance of plague in Karachi.

18,087. How many imported cases were there before the disease became indigenous?—There were 34 or 35 imported cases.

18,088. When did the first local case occur?—In the last week in February.

18,089. So that there was an interval of about seven or eight weeks?—Yes, between the first imported case and the appearance of the plague locally.

18,090. After the indigenous cases began to occur, how long did the disease prevail?—After the local cases, until the end of July.

18,091. Can you tell us how many cases there were during the whole time?—Roughly speaking, just under 600.

18,092. Have you any idea of the proportion that died?—There were 400 treated in hospital, and 35 per cent. of those recovered.

18,093. Was the prevalent form pneumonic or bubonic?—Bubonic.

18,094. Were there any pneumonic cases?—There were what I thought pneumonic cases, but in several of these there were buboes as well.

18,095. I suppose you had no opportunity of observing whether a bubonic case gave pneumonic plague to another person?—No, I could not state that.

18,096. Did you find any instances of *pestis minor* or of the non-typical forms of plague?—Of those which had very slight symptoms, and which really suffered at all there were some cases, and I think there were some in the town, but we did not discover all who actually suffered from plague.

18,097. About how many of those cases came under your observation?—About 20 of them. They were really very mild cases; they came into hospital and rested there and recovered.

18,098. Did they have high fever?—No, they did not. Their temperature was never above, perhaps, 100 or 101.

18,099. Were they prevented through personal incapacity from doing their ordinary business?—They were incapacitated from doing their ordinary business, so far as the people in the town refused to have anything to say to them.

18,100. I mean physically incapacitated?—They were not physically incapacitated; they might have walked through the plague.

18,101. How long did the fever last in the case of these people?—For a week or 10 days. I had no reason for detaining them longer.

18,102. Did you find these cases more at the end or at the beginning of the epidemic?—More at the beginning.

18,103. Did you observe that they occurred among any particular class of persons, according to age?—They occurred among young adults.

18,104. Not among children?—There were some cases among children, but the ones that I recollect most were among the young adults.

18,105. After the imported cases, did you observe mortality among rats?—Yes.

18,106. That was subsequent to the arrival of the imported cases?—Yes, and immediately prior to the occurrence of local cases.

18,107. What inference do you draw from that?—That the rats were infected by the imported cases, and when they were infected, that they infected the locality; and that the infection of the locality was the means of infecting others.

18,108. Have you anything you would like to say regarding the manner in which people get inoculated with plague?—I have looked to the prevalence of fissures and cracks and wounds, and although there are some cases in which these occurred, the numbers were not sufficient to let me draw any decided inference from it. Although it is merely a supposition, my idea is that on a locality becoming affected, the people living in it, and eating in it, and cooking their food in it, may be affected through these means; especially through the food. I have seen people in infected localities sitting on the floor, and eating their food virtually off the floor itself, and I think if the locality is so seriously affected, as I am sure it was, that this may be a means of propagating the disease.

18,109. Have you anything more definite than the information that you have just given us, regarding intestinal infection?—No, nothing more.

18,110. Has it come under your observation that rats and mice fed on cultures or infected food have developed plague and died?—No. That is what I have been told by a bacteriologist.

18,111. Do you think it possible that the dust flying about in the air communicates the disease?—I think it possible that it may produce the pneumatic form of disease.

18,112. Do you think it possible that the custom of the females in this country of cleaning their cooking pots with mud might tend to give them plague?—I think it might decidedly have a tendency.

18,113. Do you think that the practice of the people after they have performed the necessities of nature is likely to give inoculation?—I have not thought of the inoculation being propagated in that form.

18,114. What is the population of Hyderabad?—65,000.

18,115. What proportion of the 65,000 left the town between the date of the imported cases and the occurrence of the local cases?—The population was increased rather between the 1st January and the latter week of March because the people still flocked up from Karachi to Hyderabad.

18,116. After the plague began to be indigenous at Hyderabad did the population remain at its normal figure, or did it decline at all?—It declined to a certain extent, but not to a very great extent, as we took these very stringent measures to prevent the people flocking to the districts unless they had been under observation.

18,117. You think that the whole number of the population were dealt with?—Yes, except that numbers did go that were allowed to go.

18,118. When you evacuated the town how many people remained who were not provided for in the camps?—About three-quarters of the population left, I should say, the most congested parts of the city.

18,119. Were they all taken charge of in camps, or were they allowed to hut themselves?—They were allowed to hut themselves under supervision.

18,120. Were they allowed to go back to the town?—They were allowed to go back to the town for business purposes, but even there they were under supervision.

18,121. Could you give us a statement showing how the plague declined week by week after you got the people out of the town?—(Witness subsequently intimated that the Collector of Hyderabad, on being asked for the figures, stated that no reliable information could be supplied.)

18,122. Did you carry out disinfection on a large scale?—Yes, we carried out the disinfection of houses on a large scale.

18,123. Did you disinfect only those houses in which cases of plague were known to have occurred?—No, we disinfected houses in the quarters which were infected.

18,124. Did you have any means for disinfecting the clothes of people that went into the segregation health camp?—Only boiling.

18,125. Did you have any cases of plague in the health camp?—19 cases in the contact camp and eight or nine cases in the other camps.

18,126. Are you of opinion that plague is conveyed by means of the infected clothing of plague patients?—I think it is.

18,127. Did any instance come to your notice of plague being conveyed by clothes alone without personal contact?—By clothes taken from an infected person, yes. In some of the villages of Hyderabad, in the district, I think that the clothes were the means of infection.

18,128. The facts that came to your notice showed that?—Yes.

18,129. Can you give us the particulars of that?—In the village of Allahyar I think the infection was carried by clothing, especially because in that case the large percentage of the people who went there had been kept under observation. Of course, some may have escaped, we cannot say that. Our disinfection of clothing, as it was simply boiling, was very inconvenient for the people, and they tried to elude it as far as possible, and although we kept a strict observation, I have no doubt that some clothing was taken away, in fact I am certain it was, to this village, and that the clothing was the means of infecting some of the people.

18,130. How do you think that the clothing of patients who suffered from bubonic plague got infected?—Either from the discharges from the bubo, or from the excreta, or from the sputum.

18,131. You think from sputum in bubonic cases?—Yes; but in the pneumonic form especially.

18,132. Did you have corpse inspection?—We had corpse inspection in Hyderabad when plague was prevalent at Karachi in the second epidemic, and at Kotri, which is just across the river from Hyderabad, during the epidemic there.

18,133. Did the people show any objection to it?—No, not at all; they were entirely with us, I think, after the first flight of the plague in the first scare, and they helped us in every way that they could.

18,134. Who examined the female corpses?—A lady doctor.

18,135. Do you think you can ascertain by the examination of corpses whether pneumonic plague is present or not?—I do not think so.

18,136. Have there been any other cases of plague since the epidemic ceased in July 1897?—There have been no local cases in Hyderabad or in the district.

18,137. Was the town of Kotri infected three or four months afterwards?—Yes.

Lieut.-Col. W. G. H. Henderson, I.M.S.

15 Feb. 1899.

18,138. Does it lie immediately on the other side of the river to Hyderabad?—Immediately opposite, on the other side of the river.

18,139. Has any further infection come from Karachi?—Cases have come, but we discovered them at once, and we put them into the camps so that neither from Kotri nor from Karachi had we any other infection of localities.

18,140. You have had particularly favourable opportunities for stopping people, have you not, by means of the camp at Malir?—Very favourable indeed. There were only a very few cases escaped the camp, and occurred in Hyderabad during the Karachi epidemic.

18,141. Have you any information about inoculation?—No, I have no information about inoculation. We did no inoculation at Hyderabad, except in a few cases.

18,142. Have you anything to say as to the effect of climate on plague?—I think that we were helped considerably in Hyderabad by the very hot and the very dry climate there, and the nature of the soil which is rocky and sandy.

18,143. Did you find that the disease declined as the temperature increased?—From the first the temperature was very high. In March, the temperature goes up to 115 and 120, perhaps not as high as that, but in April the temperature is as high, probably, as it is in June and July.

18,144. Then your experience in Hyderabad is contrary to the opinion which some people have held that very high temperature will destroy the plague?—Well, it did not last very long in Hyderabad.

18,145. But did not the epidemic actually grow in Hyderabad when the temperature was at its highest?—From April, May, and June, the weather was very hot indeed, and the plague rose and declined during that time.

18,146. (*The President.*) From these cases of mild plague, did it come under your observation that any other persons were affected?—From my experience of my hospital, I think that the person to person infection is very rare indeed. I think that it is the locality which is the cause of the infection.

18,147. You did not observe any cases?—No.

18,148. What exactly were the symptoms of this *pestis minor*?—There was *malaise*, a feeling of indisposition and loss of appetite, and in some cases a small bubo which did not suppurate.

18,149. And a rise in temperature?—And a rise in temperature to 100 and 101.

18,150. Were there any bacteriological observations made?—I made none.

18,151. Are you aware of any having been made?—I am not a bacteriologist, and we had no means of making them at all.

18,152. Did you follow the course of any patients after you treated them?—Not after I treated them.

18,153. You had a considerable number of pneumonic cases?—No, not a considerable number; it was rare in Hyderabad.

18,154. How many do you think you saw?—I forget the numbers; there were very few.

18,155. Were they very fatal?—Yes, very fatal.

18,156. Did you see many of them shortly before death?—Yes, shortly before death.

18,157. And did you see their corpses afterwards?—Yes.

18,158. Did you observe in any of these cases whether there was any swelling in the anterior wall of the chest?—No. In some cases there was swelling in the walls of the abdomen.

18,159. Do you mean of the actual walls, or of the whole abdomen?—Of the whole abdomen.

18,160. Not restricted to the muscle or skin?—Not so far as I could make out restricted to the skin or muscle; there was a tenseness of the whole abdomen.

18,161. There was no œdema?—There was no œdema.

18,162. You speak of certain cases occurring in the contact camps?—Yes, in the camp where those actually in contact with the sick were located, or who came from houses in which cases had occurred. These were put into a separate camp.

18,163. There were a few cases in the health camp?—They were fewer than in the other camp.

18,164. Did these cases in the health camp originate some time after the patients had been segregated in these health camps?—All within 10 days.

18,165. They might have been infected in the town before that?—Yes, they might have been infected in the town.

(Witness withdrew.)

Mr. K. B. Shroff.

Mr. K. B. Shroff called and examined.

18,166. (*The President.*) You are acting as Deputy Health Officer here?—Yes.

18,167. To what places is your evidence in reference?—Malabar and Cumballa Hills.

18,168. I believe you also wish to speak of some other place?—Yes, Cutch Mandvi.

18,169. You followed the course of plague in Cutch Mandvi?—Yes.

18,170. When did it first appear there?—We were sent there on the 27th of April 1897, and I was there for 2½ months along with Dr. Wilkins and Dr. Mason.

18,171. When did the plague commence?—The plague had commenced about a month previous to our going there.

18,172. You do not therefore know much about its introduction?—No, nothing positive.

18,173. You have formed some opinion in regard to the communication of plague?—Yes.

18,174. Will you state your opinion?—I think plague was communicated in three different ways. First by the air, causing the primary plague pneumonia, which is very infectious. The second is by the rupture or abrasions of the skin, which might account for so many cases of buboes in the groin. We find almost all the poor classes, and all the servants, going about with naked feet, and they might have imperceptible abrasions between the toes, and that might also account for the great majority of people getting buboes in the groin.

18,175. Did you find many abrasions; did you search for them?—Yes.

18,176. Do they represent a large or a small proportion of the total cases?—A great many of the cases.

18,177. What kind of abrasions, and where were they chiefly?—Between the toes; there was a slight rupture of the superficial layer of the skin. We cannot find it unless we widen out the toes, and then we find a rupture of the superficial layer of the skin between them.

18,178. Assuming the virus enters one of these lesions, were there any local signs distinguishing them from other lesions? Was the actual lesion modified in any way?—No.

18,179. There was no inflammation or swelling?—No inflammation; nothing whatever.

18,180. You merely infer that the virus had thus entered because there were lesions?—Yes.

18,181. Did you find corresponding lesions to account for buboes in the axilla?—No.

18,182. Did you search the hands?—Yes.

18,183. How do you account for buboes in the axilla?—There might have been, but we did not find any.

18,184. And in the case of enlargements of the neck glands?—There we did not find any either.

18,185. Then, how do you suppose the buboes were caused there?—There was a case of a man who complained of caries in the tooth, and subsequently there was a bubo in the neck.

18,186. On which side?—On the corresponding side.

18,187. You have one case of that description?—Yes, one case recently. The patient was suffering from caries of the tooth, and after three or four days the man died, and there was swelling on the corresponding side of the neck.

18,188. You mentioned a third method of communication; what is that?—Propagation by rats.

18,189. What are your observations with regard to propagation by rats?—Last year the plague came on in Malabar Hill, and previous to that we had reports of dead rats found in all the servants' quarters, and in spite of the warning given to the servants not to sleep in those quarters, they persisted in sleeping there, and within a week we found a case of plague in those servants' quarters.

18,190. Where dead rats had previously been found?—Yes. Although the quarters were disinfected, and I had warned the owners not to allow the servants to sleep in the room, they persisted in sleeping there, and within a week I found dead persons, and cases removed. Most of those bungalows were on the seaside, and I think that the rats travelled from the drains to the foreshore.

18,191. From where did these rats travel by drains?—From the infected parts.

18,192. What would be the nearest infected parts?—Khetwadi, Girgaum, Tardeo, and other places.

18,193. Quite near?—Yes.

18,194. Have you any other observation?—We had one bungalow on the other side of the Hill where we had three cases, and dead rats were found for two or three days consecutively.

18,195. Before or after the cases?—Before the cases occurred.

18,196. How long before?—Ten or 12 days, not more than that; and the butler who was a very robust and strong man said he was very bold, and he persisted in sleeping in those rooms where the dead rats were found. After three or four days he was found lying in the compound quite helpless, with a bubo.

18,197. That was one case?—We had numerous cases like that.

18,198. How do you think rats actually communicated the plague to these patients?—I believe that rats brought the infection with them, and the germs were lying in the room.

18,199. And they infected the room?—Yes, and although we took all possible precautions to disinfect, still the cases occurred in these rooms.

18,200. Have you followed the progress of many cases of plague yourself, from the commencement to death, or recovery?—Many cases, but I had no opportunities of seeing the patients after their removal to hospital, except to Cutch Mandvi, where about 2,000 cases passed through my hands.

18,201. Did you inquire into their histories in most cases?—We had hardly any time to go into the history of all these cases. They were brought into the hospitals in a moribund condition—and we had great difficulty—we had no staff in the beginning, and we had to organise the whole thing ourselves after we reached Cutch Mandvi.

18,202. Did you see among these cases many pneumonic cases?—Yes, many pneumonic cases.

18,203. Did they occur throughout the epidemic, or at any particular part of it?—I think it was most prevalent at the time we went there in April.

18,204. Was that some time before the epidemic ceased?—In the middle of the epidemic; when we went there of course the decline commenced by seven to ten every week.

18,205. Was that after evacuation?—After evacuation, segregation, and disinfection; the whole town was evacuated.

18,206. Have you any facts to show whether a pneumonic case might obtain infection from a bubonic case?—I cannot say that.

18,207. Or *vice versâ*?—I cannot say. The pneumonic type gives infection.

18,208. Have you any cases?—Yes, we have.

18,209. Could you illustrate you answer by instances?—I can give three instances. There was one, a Hospital Assistant, who was suffering from the pneumonic type of the disease. Subsequently to that we had two persons who were attendants on this man who got plague and died.

18,210. What form of plague was it, pneumonic or bubonic?—Pneumonic.

18,211. Have you any other cases?—Altogether there were nearly ten cases from this one case of pneumonia.

18,212. Will you explain how they originated?—There were four attendants, two friends, and three or four other friends who accompanied the corpse—ten altogether.

18,213. Can you follow up the histories of these ten, and determine whether they were pneumonic or bubonic?—I find that these ten cases were of the pneumonic type. Then there was another case in another chawl. A lady died of pneumonic plague, and one of her relatives who attended her died of pneumonic plague, and a third also died of pneumonic plague—three altogether.

18,214. Do you recollect any case in which a pneumonic case produced bubonic plague, or a case in which bubonic plague produced pneumonic?—Yes, I had a case a few days back. One pneumonic case I removed to the hospital, and subsequently there have been two other cases both bubonic, in the same house.

18,215. What was the means of contact between these cases?—They were lying in the same room, and one was lying along with the patient. He was his uncle and the other was his friend. He only visited him, and did not reside in the same room. The man only died yesterday, and he had a bubo in the neck.

18,216. These were all the cases which occurred in connection with this case you have mentioned?—Yes.

18,217. You have had some experience with curative serum, have you not?—Yes.

18,218. Would you describe your experience?—When I was in Cutch Mandvi we had nearly 30 cases inoculated with Dr. Yersin's serum, and out of these only 11 recovered.

18,219. Did you take charge of the patients in these cases in which curative serum was employed?—Yes, I myself inoculated them.

18,220. Were you following the history of these cases?—Yes, with Dr. Mason.

18,221. You were doing it in conjunction with Dr. Mason?—I was under Dr. Mason, and I was in charge of those wards.

18,222. There is a clinical record of these cases?—Yes, but I differed from Dr. Mason in some of the cases he put down as plague. I took them to be malarial fever. That is the reason why I give 11, and I believe that Dr. Mason has shown a higher figure. Dr. Mason's theory was that these were plague cases that were inoculated with Dr. Yersin's serum, and who subsequently recovered, but my opinion was that they were malarial cases.

18,223. How many cases does this apply to?—I have no figures.

18,224. Were they a small or a considerable number?—Only a difference of two or three.

18,225. It does not affect the general result?—No.

18,226. What is your opinion of the value of Dr. Yersin's curative serum?—I do not think it is of any value; I am against it.

18,227. You had experience also of preventive inoculation?—Yes, I inoculated 1,242 persons up to the 12th instant, of which 999 were for the first time, and 243 for the second time.

18,228. At what period of the epidemic was this?—Since the last 14 months.

18,229. What was the result of your inoculations on the whole?—I have no case with any bad after effect, excepting one case after the second inoculation, where there was severe purging, vomiting, fainting, and urticarial rash lasting for about an hour-and-a-half.

18,230. In so far as you can estimate the value of the inoculation in preventing plague, what was your opinion?—I think it was a great safeguard.

UNIVERSITY OF EDINBURGH USHER INSTITUTE

Mr. K. B. Shroff.

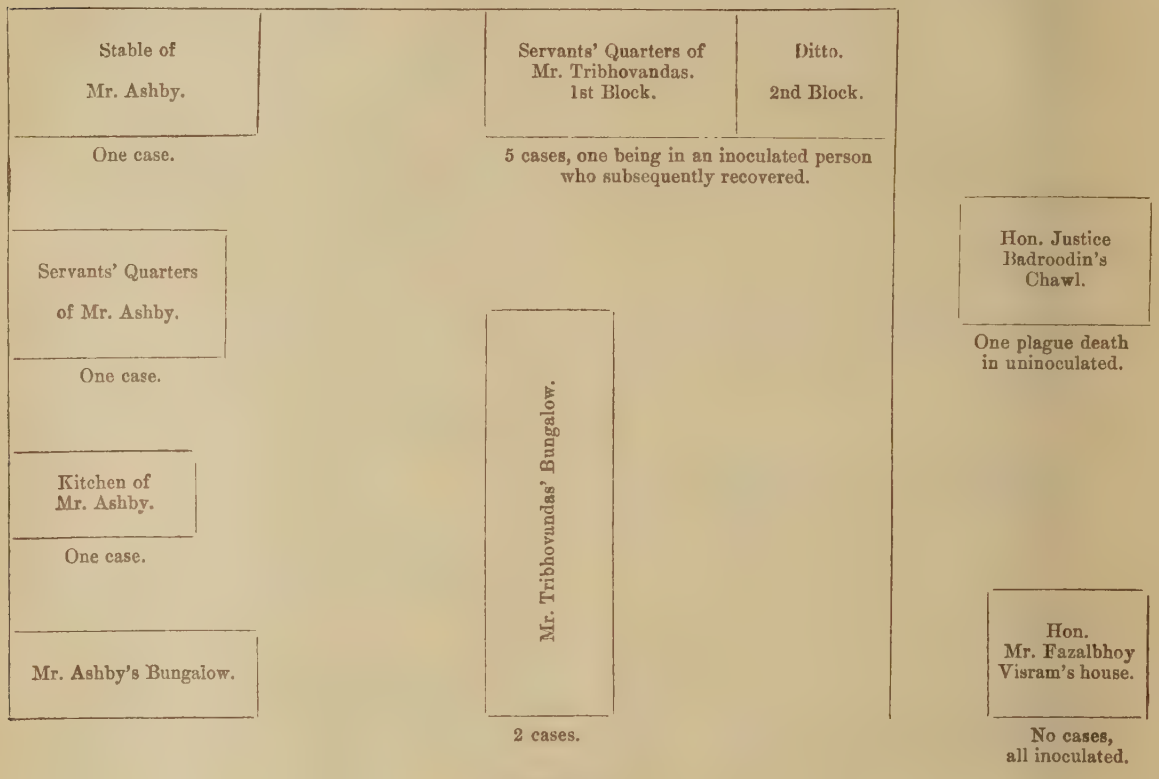
15 Feb. 1899.

18,231. Have you got any facts and figures which support that view?—Yes. In Warden Road, just near the Battery, there is a big compound containing three bungalows; behind these, and separated only by a 6 foot wall, there are two chawls, and two other bungalows, and adjoining those again there is another bungalow, and servants' quarters. In the front bungalow, containing altogether 75 servants, only one man was inoculated. Here there were altogether 11 cases of plague, including the one inoculated, who subsequently recovered. This man was inoculated on 30th January 1898, and got plague on 10th March 1898, *i.e.*, 40 days after.

18,232. The only man who was inoculated also acquired plague?—Yes, 40 days after inoculation; he subsequently recovered in the hospital, but died later on of some other disease.

18,233. How long afterwards did he die?—About two months after his discharge from the hospital. Behind these bungalows almost all the people were inoculated, and here there was only one case amongst the uninoculated who subsequently died. In the neighbouring house all the servants were inoculated, and there was no other case there. I have a sketch here which illustrates it, as follows:—

A Rough Sketch of the Position of the Bungalows in Warden Road near the Battery.



Stable of Mr. Ashby.
One case.
Servants' Quarters of Mr. Tribhovandas. 1st Block.
Ditto. 2nd Block.
5 cases, one being in an inoculated person who subsequently recovered.
Hon. Justice Badroodin's Chawl.
One plague death in uninoculated.
Servants' Quarters of Mr. Ashby.
One case.
Mr. Tribhovandas' Bungalow.
Kitchen of Mr. Ashby.
One case.
Mr. Ashby's Bungalow.
2 cases.
Hon. Mr. Fazalbhoy Visram's house.
No cases, all inoculated.
Warden Road.

18,234. Have you any statement which shows the results in all the cases you inoculated?—No, I have only two or three instances.

18,235. Are these selected instances?—Yes.

18,236. You cannot tell me the result regarding the whole of these 1,242 persons, as to who acquired plague afterwards?—No, I cannot say that, but most of them reside in my ward, and I would have known about it if they had acquired plague.

18,237. Supposing they went away from your ward?—Then I could not trace them, but in that case the other wards would be making inquiries about them.

18,238. It is just within the bounds of possibility that you would have heard?—Of course I could not be positive about it.

18,239. (*Mr. Hewett.*) Do you think that the practice of using earth for the purpose of cleaning cooking utensils and other things may lead to people being inoculated on the hands with plague?—Yes, it might.

18,240. Have you noticed any difference in the proportion of males and females who get plague?—I find a greater proportion of females than males. I found the same thing in Cutch Mandvi also, not a very great proportion, but a little more than in the males.

18,241. Did you notice whether the buboes in the case of females were generally femoral or not?—They were mostly femoral.

(Witness withdrew.)

Mr. K. A. Dodihalkar

Mr. K. A. Dodihalkar called and examined.

18,242. (*The President.*) You are a Licentiate of the College of Surgeons, Edinburgh?—Yes.

18,243. (*Mr. Hewett.*) Are you employed in the Health Department in the Byculla Division of the town?—Yes.

18,244. Are the inhabitants of that chiefly Hindus or Muhammadans?—Half Muhammadans and half Hindus.

18,245. Is it a poor district?—Yes, a very poor district.

18,246. Is it very congested?—Yes, very congested.

18,247. Has plague been very bad there?—Yes.

18,248. Is it very bad there now?—Yes.

18,249. What is the population of the Division?—50,000.

18,250. How many cases of plague occur there now daily?—At present, I believe, it comes to nearly 25 a day.

18,251. Are they mainly pneumonic or bubonic?—Mainly bubonic.

18,252. Have pneumonic cases come under your observation too?—Yes, they have.

18,253. Have you ever noticed any case in which a patient suffering from bubonic plague has communicated pneumonic plague to another person?—I have not traced it, but one person in the same house

has got pneumonic plague while the other persons have had bubonic plague.

18,254. Have you had many instances of that?—No, very few.

18,255. Do you think that you get the majority of plague cases now?—Yes, we do.

18,256. Do the people report them?—The people do not report so much.

18,257. But you find them out yourself?—They are found in the cemetery, by the extra number of deaths.

18,258. Then you find them after the people are dead, not while they are sick?—Not while they are sick.

18,259. Do the people object to go to the hospital?—They do.

18,260. I see that you say in your précis of evidence that if you can assure them of their recovery they would go; that is rather a difficult thing to do, is it not?—They do not see the recoveries, and they do not like to go; they are ignorant people.

18,261. Do they object to going to segregation camps?—Yes.

18,262. What is their objection?—They are put to great trouble in removing their luggage and baggage, and at the same time they say that these huts will take fire at any time, and there is no certainty about their safety.

18,263. Are you at present employed on plague work?—No, I am on sanitation work.

18,264. On what sanitation work?—The removal of filth from the streets and houses, getting the w.c.'s cleaned, and, where the houses are dirty and insanitary, giving notice to the landlords to improve them.

18,265. Are you employed on disinfection only?—Not at present. I was last year.

18,266. (*The President.*) You said that when the houses are insanitary you give notice?—Yes.

18,267. Who is the judge of whether the houses are insanitary or not?—I am.

18,268. On what grounds do you proceed?—If the houses are dark and have no means of light, no windows, no ventilation, if they are damp, and the walls dirty, then I give notice to the landlord.

18,269. Do you give notice yourself directly, or through some other official?—I write to the Municipal Commissioner through the Divisional Health Officer.

18,270. Have you had occasion to give such notice in the case of a large number of houses or not?—I have.

18,271. In how many instances, roughly, have you given such notices?—In the last two years I have been working with the Health Department, and I may have given about 1,000 notices.

18,272. Have you any recollection as to the number of instances in those 1,000 in which sufficient action was taken as the result of your notice?—Some houses are demolished, and in some houses windows are made to admit more light and ventilation.

18,273. In what proportion of the 1,000 has action been taken?—About one-fifth.

18,274. What has happened to the remainder?—Their cases have been referred to the Engineering Department, and action will be taken in due course.

Mr. K. A. Dodihalkar.

15 Feb. 1899.

18,275. In regard to the insanitary conditions, to what extent do you take notice of overcrowding?—We do not take any steps to remove overcrowding. May I mention a few of my ideas with regard to the origin of plague?

18,276. So far as you have got facts, we shall be very pleased to hear them?—In the year 1893, I was living in the Main Road in Khetwadi. My cat got a bubo on the neck which suppurated after one month, and the cat recovered. I was not aware of plague at that time, and I did not try to find out what it was. In the same month my brother got a bubo in the axilla, with high fever of 105 degrees. The fever was continuous for about a month, and then the bubo suppurated, and discharged the pus; he recovered, and he is living now. At the same time there was a little child about four years old living in front of my house. He had a small inguinal gland, with very slight fever, about 100 degrees, without any treatment it disappeared. I lay these facts before you to show that plague is not new in Bombay, and in India; but it is one of the old diseases, and the present severe form is only a new type. In Malad, a place about 30 miles from Bombay, the people are quite aware of this disease, they call it rat fever, and they describe it like this: that the rats fall from the roofs dead, and then if the people live in the house they get the fever themselves, and they die.

18,277. When did this happen?—About 15 years back. I do not know myself, but friends of mine who have been in Malad told me of this.

18,278. Do you know whether this rat fever is now present in Malad?—It is not now. 10 or 15 years back it was there, and they get it every 10 or 15 years; it is a very marshy place. About the first of this month one instance occurred. In my neighbourhood there is an institution called the Gouraki Press. There were some rats found dead in the compound, and there were two white rats that were kept in a cage in the institution for amusement. They died one after the other, and then one of the compositors got plague, and he was removed to the hospital and died there. This fact I want to place before you to show that it is not by contagion, it may be by infection, but the rats themselves got the disease in the vitiated air.

18,279. These rats were in a cage?—Yes, I went there every day, and I used to notice them.

18,280. Where was the cage?—It was on the roof.

18,281. It was sometimes taken down?—Yes, at dinner time.

18,282. Were the rats allowed to come out of the cage sometimes and run about?—No, they only placed the cage near the dish and gave them food.

18,283. Were there any cases of plague in human beings in this house or room?—Last year there was a case of plague.

18,284. I mean at the time?—Yes, one person got plague and was removed to the hospital.

18,285. At the same time or previous to the rats?—Previous to the white rats, but some rats had been dead before.

(Witness withdrew.)

MR. K. S. ENGINEER, called and examined.

Mr. K. S. Engineer.

18,286. (*The President.*) I believe you are a medical man?—Yes.

18,287. What are your qualifications?—I am a Fellow of the Chemical Society, London, and a Licentiate of Medicine and Surgery of the Bombay University.

18,288. What has been your association with plague?—As a medical practitioner.

18,289. You have no official connection?—No, only private connection with plague cases.

18,290. You come here as a private practitioner to give us your experience of plague?—Yes.

18,291. I think you have some opinions as to how plague entered Bombay?—Yes.

18,292. What are your opinions?—My opinion is that plague was imported into Bombay from Hong Kong.

18,293. On what grounds do you hold that opinion?—Because plague first occurred over those parts where articles of merchanise are landed from China.

18,294. What is the connection with China?—At that time plague was raging in Hong Kong.

18,295. When did the first case of plague come under your observation?—On the 16th of July 1896

18,296. Could you give us some account of that case?—A Parsee gentleman, a Dubash, *i.e.*, a stevedore by occupation, brought a Hindu Superintendent (muccadum, *i.e.*, overseer of coolies) to me who was working

Mr. K. S. Engineer.

15 Feb. 1899.

on the Port Trust Estates. The patient was suffering from high fever, and when I examined him I found a bubo in the left groin. Of course, at the time I could not decide whether it was a real case of plague or not; but subsequently from the observation I made, and from the experience I gathered, I can now safely vouch that the case I treated was one of plague.

18,297. How did that case originate?—The man came to me and told me that he was working somewhere near the docks, and had got a high fever, accompanied with chills.

18,298. Were there any similar cases at the same time?—On that very day I had none.

18,299. How soon afterwards did you see cases of a similar kind?—After a fortnight a similar case occurred.

18,300. Were these identified as true cases of plague?—The symptoms in both the cases were different. This second case was a pneumonic case. This case was seen with me by the late Dr. Manser. We treated it as pneumonia. Now, however, I have come to the conclusion that this case which I saw in consultation with Dr. Manser was a pneumonic case.

18,301. On what grounds have you come to that conclusion?—The pneumonic symptoms differed. They puzzled us at the time.

18,302. What difference?—The pneumonic symptoms were gradually running; they did not appear all of a sudden. When I saw the patient I found slight congestion at the left base—it was a left pneumonic case. When I inquired into the history of the case, from the symptoms one could not conclude that it was a typical pneumonic case—it was not a typical case of pneumonia; the sputum was not free, it was very scanty, and not rust coloured, but accompanied with blood. The symptoms merged suddenly, in such a way that we wondered whether it was a real pneumonic case or not. We found out subsequently, however, that it was a real pneumonic case.

18,303. You had definite symptoms of pneumonia?—Yes.

18,304. What definite symptoms?—Dullness at the left base, accompanied with tubular breathing, and increased voice sounds, and crepitations. This case lasted three days. The symptoms merged according to the grades—from one grade to another.

18,305. The patient was ill for three days?—Yes.

18,306. Did the patient die, or did he recover?—He recovered in three days.

18,307. But these symptoms were sudden?—Yes, the stages merged from one to another in such a way that we could not decide whether it was a real pneumonic case or not. I have come to the conclusion now that it was a pneumonic case.

18,308. At the time you had no evidence that it was a pneumonic case?—On the first day there was no evidence of pneumonia.

18,309. The whole time you saw this patient you were not satisfied that the symptoms pointed to pneumonia?—No.

18,310. But now you think they probably did?—Yes.

18,311. State why you think so?—To my mind it seems to me that it was a pneumonic case—only from the conclusive symptoms.

18,312 They appear to be inconclusive?—The symptoms were inconclusive in the beginning, but conclusive in the long run.

18,313. In what way conclusive?—In ordinary pneumonic cases the symptoms run from one grade to another, but in this case the symptoms were sudden, and disappeared all of a sudden.

18,314. Did you have any bacteriological examination?—No, we did not suspect anything.

18,315. To my mind it looks doubtful whether it was plague or not?—I have seen lots of cases, and I have now come to the conclusion that it was a case of plague pneumonia.

18,316. There is nothing more than you have stated?—No.

18,317. I believe you have some statement to give us with regard to the chief factors which propagate the plague?—Yes; there are three factors. 1st. Overcrowding; 2ndly. Increase in the sub-soil water; and 3rdly, Bad drains. These, in my opinion, are the factors which cause plague to flourish.

18,318. What evidence have you which enables you to say that overcrowding causes plague to flourish?—Because in overcrowded districts we find cases occurring.

18,319. Will you give us some facts?—Supposing a family occupies a room 4 feet by 6 feet, there may be 10 or 20 persons there. If a plague case were to occur there, the other members would be found to suffer as well.

18,320. Have you any examples of that?—I have seen many.

18,321. Will you state them?—I know the case of a Parsee who was sick with plague. He occupied a very small room, and he had three children by his side. He died. The next day his son was attacked, and he recovered after a time. But in that very room, within a period of a week or so, three patients were affected with plague.

18,322. How many people occupied this room?—Five.

18,323. Were they all affected?—Out of these five three were affected. They were removed from the locality. Wherever there is overcrowding we meet with many cases.

18,324. Does your experience embrace an overcrowded district as well as an overcrowded house?—Yes.

18,325. Can you illustrate that by the case of Bombay?—Of course, Bombay is an overcrowded place.

18,326. But the proportion of overcrowding differs in different parts of Bombay, does it not?—Yes.

18,327. What do you consider the most overcrowded district, and has plague been most prevalent there?—Mandvi, in my practice, I find.

18,328. Is that the most overcrowded district?—I should think so. I call Mandvi an overcrowded place.

18,329. I asked which was the most overcrowded district; are all the districts overcrowded?—I should say Dongri and Mandvi are the most overcrowded districts in my practice.

18,330. Is it within your knowledge that the largest percentage of cases to the population has occurred in these two districts?—I cannot give you the exact ratio.

18,331. Is it within your knowledge or not?—I cannot tell you.

18,332. You cannot tell us from personal experience whether an overcrowded district is productive of the greatest amount of plague?—From my personal experience, taking the localities I practise in, I consider Mandvi an overcrowded place.

18,333. But you have told me that all Bombay is overcrowded; I ask you which is the most overcrowded?—Mandvi, so far as I know. In certain chawls many persons were affected one after the other.

18,334. That, again, bears upon the overcrowding of special houses. Then with regard to the next point, what have you to say with regard to the increase in the sub-soil water?—An increase in the sub-soil water fructifies the germs.

18,335. That is theory, I want facts. Why do you say that? Can you mention a district where the sub-soil water is in a condition which you think is especially favourable for the increase of plague, and can you tell me whether plague is especially prevalent there?—At Mandvi I find the sub-soil increasing, and I find that the level of the water in certain wells had increased in those localities where I practise. If you were to examine the water of certain wells in Bombay you would find nothing but filthy water from the surrounding drains.

18,336. It is not merely the fact that the water is high, but the fact that there is filth in the sub-soil water?—The sub-soil water has a certain effect upon the propagation of plague, that is my argument. Wherever there is an increase in the sub-soil water there plague cases are found in abundance.

18,337. Can you tell me where there is a special increase, and whether plague has increased in that district?—In Mandvi there has been an increase in the sub-soil water, and there cases are still running on, and

have been doing so from the time of their commencement.

18,338. Is Mandvi the only part of Bombay where the sub-soil water has increased?—The sub-soil water has increased in Girgaum and Dhobika Talao.

18,339. Is the plague worse there?—Plague cases are found in abundance there as well.

18,340. They are found, I understand, all over Bombay; but is the total number larger in places where the soil is waterlogged?—Yes, where the soil is waterlogged.

18,341. What have you to say with regard to bad drains?—In most parts of Bombay we find the drains are badly laid, badly cemented, and badly paved, the consequence being that there is oozing from the joint connections. This tends also to increase the sub-soil water. I have noticed that wherever there is a smell from the drains plague cases occur.

18,342. Do you mean to say that in every place where you have smelt bad drains you have found cases of plague?—I have seen plague cases in those very houses.

18,343. Is there any other point bearing upon the diffusion or increase of plague which you would care to bring before us?—These factors, in my opinion, increase the propagation of plague.

18,344. I wish you had been able to give more facts, because we can get opinions to any extent. Have you had any experience of preventive inoculation?—Yes.

18,345. What experience?—I think inoculations immunise persons.

18,346. What is your experience with regard to inoculated persons?—All the persons who have been inoculated are now living, though they are scattered all over Bombay, and living in the worst possible localities.

18,347. They are all living?—Yes, they are all living.

18,348. When did you inoculate these persons?—I inoculated in 1897, 1898, and 1890.

18,349. What record have you kept?—I jot down the names, ages, and addresses according to the form prescribed by Prof. Haffkine. We send a return of these people every week.

18,350. You trace them out weekly?—Yes. We inoculate those persons who come for inoculation.

18,351. After inoculating them what do you do? How do you trace them?—After I have inoculated them I have my eye on these patients. I know them very well; they are not outsiders. I have inoculated about 600 families.

18,352. How often do you see these 1,800 persons?—Every now and then.

18,353. What do you mean by every now and then?—If any person died I should know it at once.

18,354. How?—Because they are within my range. I have to treat them—treat their families, and so on.

18,355. You have no other means of tracing the after history of these persons?—In addition to that I read the daily mortuary returns, and I do not see any of the names of these people in the returns.

18,356. These daily mortuary returns give the names, do they?—Yes.

18,357. Anything more?—Nothing more.

18,358. I should fancy there would be many persons who had not been inoculated by you who had the same name?—I could find out at once from the surname.

18,359. But there must be several surnames the same?—I do not think so.

18,360. In all Bombay?—I do not think so. I have inoculated most of our Parsees.

18,361. That is the only way in which you can identify them. I suppose?—No.

Mr. K. S. Engineer.

15 Feb. 1899.

18,362. (*Mr. Cumine.*) Have you measured the height of the sub-soil water in the various quarters of Bombay?—I have not measured it, but I have seen it with my own eyes where the borings were taken by the Municipality.

18,363. Do you know what the *relative* height of the sub-soil water is in different parts of Bombay?—Yes.

18,364. What is the height of the sub-soil water in Girgaum?—About 12 feet.

18,365. What is it in Nagpada?—I cannot say. I am not interested in that locality.

18,366. Then you do not know the relative height of the sub-soil in each quarter of Bombay?—No.

18,367. If you do not know the relative height of the sub-soil water in the different quarters of Bombay, how can you say that there is a connection, a relation, between the height of the sub-soil water in the different places, and the extent of plague in those places?—Where there is an increase I find many more cases cropping up. In certain parts of the town, wherever I have seen the relative height increasing, there I have found many cases. According to your statement I cannot tell you.

18,368. You spoke about leakage from the drains; have you inspected all the drains of Bombay to find out which leaked most?—I cannot say in which locality the drains leak most, but from my own personal observation I can say that in most parts of the town there is a leakage.

18,369. But have you inspected them all to find out which of them leaked most?—I cannot answer that question.

18,370. How many of these 1,800 people have died since you inoculated them?—Not one.

18,371. How long is it since you inoculated them?—I commenced my inoculations in January 1897.

18,372. So that in two years out of 1,800 people no one at all has died?—Not one of them has died.

18,373. You say that these 1,800 people represented 600 families; and that if anybody had died you would have heard of it, because there is always somebody from the 600 families coming to be treated. Do you mean to say that there is always someone ill amongst them?—I generally see them once a fortnight.

18,374. Even if one member came to be treated, the whole family would not come, would they?—I generally inquire how they are after inoculation.

18,375. (*The President.*) Is there much sickness among these 600 families?—In any community where there is a large number of men, every now and then we find certain seasonal diseases cropping up.

18,376. Is there much sickness amongst the 600 families?—Not much, I should say.

18,377. How can you see them frequently if there is not much sickness?—Some come for ordinary treatment.

18,378. Do you mean when they are not ill?—When they are casually ill.

18,379. If they are not ill, and there is very little sickness among these families, they can only come to you very seldom?—At the same time I generally inquire after them.

18,380. Do you go to see them?—No. I inquire after the relatives when they come to see me. I see them once a fortnight.

18,381. What do they come to see you for?—For treatment.

18,382. But you say there is very little sickness?—In cases where I have performed inoculations I inquire of the relatives.

(Witness withdrew.)

Major Richard Baker, I.M.S., called and examined.

Major R. Baker, I.M.S.

18,383. (*The President.*) I believe you are in the Indian Medical Service, and have the degrees of M.A. and M.D.?—Yes.

18,384. You have had experience in Upper Sind and Satara?—Yes.

18,385. In the first place, what have you to tell us with regard to the measures which were adopted?—The measures adopted in Sind were for the early detection of cases, for the isolation of the sick, for the segregation of contacts, and health camps. In addition to that in

Major R. Baker, I.M.S.

15 Feb. 1899.

Sukkur we had a fourth camp, which was used as a detention camp. It was an observation camp for people coming in and going out of infected quarters. The measures for the detection of the sick at an early stage were various. Small rewards were offered for information; we made private inquiries, and we had search parties.

18,386. What rewards did you find necessary; what sum did you offer?—Very small sums—eight annas and one rupee. Private inquiries too, were made. A number of reliable officers were always deputed where plague had broken out, and we made as many inquiries as possible ourselves, also through our Government servants and neighbours. In addition to that there were search parties.

18,387. Was it a voluntary or paid organisation?—We had both. Speaking for myself I am inclined to think that the voluntary organisations were more useful in their results than military search parties.

18,388. I believe you employed these measures in a large number of towns and villages?—They were employed in Sukkur. In Shikarpur, which was curiously exempt from plague, I told the people that if they used all possible precautions themselves they would possibly avoid the necessity for sending military search parties. I am inclined to think that that had a very good effect, because the natives did not care for military search parties.

18,389. You were employed in Hyderabad?—For a short time.

18,390. And you were also employed in Daharki, Tatta, Karad, Lanauli, and Igatpuri?—Yes.

18,391. And you adopted the measures which you have described at all these places?—Yes. I may say that my functions were more supervisory and advisory than actually executive, because Mr. Wingate employed me in that capacity very largely. He sent me all about the country. In Tatta I found that this elaborate method of having so many camps was by no means necessary. The great dread was that we should have a camp epidemic in the segregation camp, but according to my experience there never was a camp epidemic in the segregation camp. If a segregation camp is properly organised and looked after, and each inmate inspected every day, and each case as it occurs at once sent to the isolation hospital, and proper methods taken for disinfection, I have never, in my experience, seen any symptoms of even the beginning of a camp epidemic.

18,392. What course did you there adopt?—I combined the segregation, health, and detention camps.

18,393. What did that leave you with?—A hospital for isolation, and one large camp. I found that workable for this reason, that when a disease breaks out in a place there is an exodus from that place, and as the disease abates there is a return of the fugitives. The amount of camp accommodation for both is practically constant, otherwise it would not have been workable. Of course it was much more economical, and much more easily managed than a series of separate camps.

18,394. Did you usually get very early information of the first imported case?—In Hyderabad we did, and in Sukkur at the beginning of the disease we did not: but when the people realised the nature of the disease, many of them came to inform us themselves—even the relatives came to inform us.

18,395. There were some villages in which you got early information of the first importation?—Yes.

18,396. What measures did you adopt in those villages?—The imported case was removed to hospital, and the people in the house were removed to the segregation camp, and the house itself was disinfected.

18,397. What was the result?—Mr. Dodgson, the Collector of Hyderabad, and myself, are distinctly under the impression that our efforts in that direction did stall off the occurrence of local plague in Hyderabad for some time, because there were at least five cases of imported plague spread over a long time before we had a local case, and we can trace the reason why we got that local case.

18,398. In any of these places did you actually prevent plague from becoming local?—Yes, for a time, that is our belief.

18,399. Finally plague became indigenous?—Yes.

18,400. When plague became indigenous what did you do?—When it became indigenous we cleared out larger areas.

18,401. Did you find that effective?—I cannot speak for Hyderabad. I was transferred from Hyderabad. I was doing work as Civil Surgeon of Hyderabad before I took up my special plague duties. Subsequently I was busily engaged in Sukkur.

18,402. Was Hyderabad the only place in which you partially evacuated areas?—I may mention that when I first went to Sukkur I found one imported case, and had it removed. Apparently, however, there was another imported case which I failed to move, and within a week or ten days I was sent to go to Sukkur again. I found that this second case had established a large centre in a temple, and measures had to be taken.

18,403. What was done; was the area evacuated?—This case occurred in a temple, and many other cases occurred there. People have a tendency to go to temples to die. This man went to the temple to die, and he infected the people in the temple. A large number of people were found in the temple dying or dead. The temple was dealt with the aid of a gang of 20 coolies, of whom 5 died of plague in a week, owing to the fact that there was no previous disinfection of the temple.

18,404. Did you evacuate the area?—That area was evacuated, but not properly evacuated.

18,405. Partial evacuation took place?—I would prefer to call it ill-directed evacuation. The result was unsatisfactory.

18,406. Was there entire evacuation afterwards?—Afterwards the disease spread over the place. I can give you a very successful instance of evacuating a large portion of a town. The part of Sukkur known as Gharibabad was infected. There were supposed to be 1,000 people in that part of the town, and in 16 days they died, at the rate of 25 a day, leaving 601 people in the town. During those 16 days, with the aid of the Railway Company, we erected a very complete camp—the most complete I have ever known. On the 17th day the 601 people were moved out.

18,407. With what result?—With the result that the 601 people escaped plague, except one who developed the disease within 24 hours of his removal to camp.

18,408. You did not have another case in the segregation camp?—No.

18,409. What happened in the portion of the town from which they were evacuated?—The people went back gradually.

18,410. Plague stopped there?—There was nobody to get plague. Absolutely every individual was segregated. The whole of this outlying portion of the town, which was quite separate, was evacuated.

18,411. The other parts of the town were not infected?—Not to that extent at all.

18,412. Did you have any case in which you at once evacuated a whole town or village without having first carried out partial evacuation?—No, I do not think so.

18,413. Your experience has been of cases in which there has been partial evacuation, afterwards followed by complete evacuation?—Yes.

18,414. As a rule, you found partial evacuation sufficient?—Yes, temporarily.

18,415. But on recourse to complete evacuation it was successful?—Yes.

18,416. How long did you generally keep people out of a town or village?—In Sukkur the people were kept out of the town longer than would otherwise be necessary, to admit of complete disinfection of their houses.

18,417. How long?—They were kept out of the town for about a month.

18,418. In the meantime the houses were disinfected?—Yes.

18,419. And the people were then allowed to go back?—Yes.

18,420. Was there any recrudescence of plague in the disinfected houses?—No.

18,421. Total evacuation combined with disinfection have been very satisfactory in your experience?—Evidently so.

18,422. In what position do you put these measures in regard to other measures?—In the first position.

18,423. I believe you have had some experience with regard to disinfection alone, apart from anything else?—Yes.

18,424. What are your views as to the value of disinfection?—Perhaps the best way that I can point that out to you is the danger of the want of disinfection, and the value of it in other places. There are cases as to the value of disinfection in Karachi, which came under my notice incidentally, where the plague wards were daily drenched with perchloride of mercury.

18,425. Plague wards?—Wards of the Plague Hospital —the floors.

18,426. But at the hospital there were many other conditions besides; I would rather you would take ordinary habitations, because hospitals are not comparable with ordinary habitations?—It would be easier to give you an example of the failure of disinfection where segregation is incomplete, that is to say, where the unaffected inmates are still left in the houses.

18,427. What is you experience?—At Igatpuri, during the rains, it was extremely difficult to segregate, I was told, because of the want of places in which to put the segregated people. They had no accommodation, and consequently segregation was not attempted, but each case was removed to hospital as it occurred, and each house in which plague occurred was disinfected. The result of that was that other cases which were still in the incubation stage at the period of the isolation of the infected person developed, and fresh cases continued to develop in the houses, each case being followed by the isolation of the patient and the disinfection of the quarters. In one instance what was found to be necessary as often as seven times.

18,428. Your view is that disinfection alone is inefficient?—Certainly.

18,429. Have you any experience of protective inoculation?—I have no statistics to offer. My impression is a general one.

18,430. What is your impression based upon?—Merely upon observation but without figures, because I had nothing to do with inoculation myself. In the course of my inspection work I had occasion to observe what the effects had been in a general way. The most striking was at Lanauli, where the people living on one side of the railway line had been subjected to inoculation, and the people on the other side of the line had not been subjected to inoculation. In the place where inoculation had been made use of the town was thriving and full of people, and the other side of the line was absolutely empty. I came upon this merely by accident.

18,431. One side had a greater amount of plague than the other?—One side had plague and the other had none.

18,432. How much plague was imported on each side of the line?—I made inquiries and was told there was no difference, but I do not know about that.

18,433. Is that your whole knowledge with regard to inoculation?—Yes. I have no special knowledge of it.

18,434. (*Mr. Hewett.*) I understood you to say that you considered that at Hydérabad you practically stopped the possibility of infection by dealing with the imported cases as they occurred?—Yes.

18,435. Dr. Henderson, who was there after you, said that the infection of rats followed the imported cases and occurred before the local cases; have you observed that anywhere?—When it does it occurs almost simultaneously with the occurrence of the first indigenous case.

Major R. Baker, I.M.S.

15 Feb. 1899.

18,436. Do you mean that it occurs simultaneously with the first indigenous case that is detected?—Yes. I have never heard of a distinct case of rats having been found dead any length of time before the detection of the indigenous case.

18,437. Do you think it possible that an imported case occurs and infects the place and then the rats become infected, and that simultaneously with the infection of the rats human beings become locally infected?—That is the way in which I think the disease becomes local.

18,438. Whatever you do with the imported case you have always that danger?—Yes.

18,439. Did you have in Sukkur much pneumonic plague, or was it mainly bubonic?—My experience was in walking through the hospitals, which I did every morning, although I was not in charge of them. I do not know the normal proportion, but I should say there was a fairly large number of pneumonic cases.

18,440. Did any example come to your notice of a bubonic case communicating pneumonic plague or *vice versâ*?—No, I have no information upon that point

18,441. The temperature at Sukkur was extremely high, I think?—Yes.

18,442. Did you notice that the disease gained strength as the temperature rose?—Up to a certain point it did.

18,443. The rise of temperature did not seem to check it?—No.

18,444. What is the population of Sukkur?—There are three towns really—Sukkur, Rohri and New Sukkur, and I should say the total population was about 40,000.

18,445. What number of people had you in the segregation and health camps there?—600 people.

18,446. Only 600?—Only 600 in the only camp worth considering, the others were very small.

18,447. Therefore there was very little evacuation of the town?—The evacuation was of an outlying portion of the town.

18,448. The main portion of the town remained unevacuated?—Yes.

18,449. When a plague case occurred in the main portion of the town, what measures did you take?—Isolating the case and segregating the people, but the numbers in the town itself were very small compared with the numbers at Gharibabad.

18,450. You left the neighbours alone?—No, we put the neighbours into a segregation camp, but the numbers there were very small compared with the numbers at Gharibabad, so that that would hardly affect the question.

18,451. (*Mr. Cumine.*) Did you disinfect the clothing and effects of those 601 Gharibabad people when you took them out into the health camp?—Yes.

18,452. Do you think that is necessary to make the plague stop on evacuation?—Yes, I think it is safer at any rate.

18,453. With regard to Lanauli, does the railway line divide it equally into two parts?—Fairly equally, probably the greater portion were on the healthy side.

18,454. Is there any difference between the classes of people who live on the two sides?—No.

(Witness withdrew.)

Mr. G. W. ROUGHTON called and examined.

Mr. G. W. Roughton.

18,455. (*The President.*) What district are you prepared to speak about?—Kolaba and Fort Northern.

18,456. (*Mr. Cumine.*) You began plague work, I think, on the 31st December 1896?—So far as the Volunteer Artillery was concerned, I did.

18,457. With whom did you begin the work?—With the members of my corps, the Bombay Volunteer Artillery; but that was nothing to do with the house-to-house inspection, which was also worked. That was when we started doing actual plague work at the request of Dr. Weir. That was on the 31st December 1896.

18,458. What did you begin to do in March 1897?—I was appointed President of the Justices, who had been asked by Lord Sandhurst to look after the work, and I had the whole of the district from the Victoria Terminus to Kolaba under my control.

18,459. That would include the two parts called Fort and Kolaba?—Yes.

18,460. Did you retain the whole district throughout?—No; as a matter of fact during the first three or four weeks the work was confined, as far as I had anything to do with it—Mr. Raikes being my assistant—to work at Kolaba. Fort Northern was then a separate district. Although I was appointed plague authority for both districts, really we confined our attention to Kolaba.

18,461. The Upper or the Lower?—Both. From Sassoon Dock to Kolaba was not much trouble.

Mr. G. W. Roughton.

15 Feb. 1899.

18,462. When you began this house-to-house visitation in March 1897 who formed the search parties?—They were entirely members of the corps with the addition of Mr. Raikes and Mr. Howard, Mr. MacDonald (not Mr. James McDonald), and one or two officers of the Preventive Department.

18,463. The plan adopted, I think, was to meet every day at a given rendezvous, and decide what houses were to be searched?—That is so. I have here a map* of the Kolaba district, and I have marked on it with a red cross every house which is the centre of infection.

18,464. Was it possible for cases to escape detection or were the search parties too numerous for that?—At first it was possible, but eventually it was absolutely impossible. Then there was another thing; as it was seen that the whole agency was European, it was impossible for cases to be imported. That is what we had to struggle with at first. The result was that in something less than a month we had driven the whole of the plague out of our district. Of course it went to others, but that we cannot help.

18,465. In the first epidemic from March to June 1897, I believe some resistance was encountered?—Yes, a great deal; but in the second, from November 1897 to March 1898, there was no resistance encountered at all, except in Hamal Lane where there were five Muhammadan houses. That was the only place.

18,466. Did you find the inhabitants willingly present themselves for examination?—Yes. I never made so many friends in my life. You must remember that there is a great deal of zulm (oppression) in this sort of thing, but the remark which was commonly made to us was "Come every day, and then there will be no zulm." They were quite pleased to see us. We got to know pretty well everybody in the district, and everybody in the district was seen once at least in three days. I had such a large staff that, the place being not very large, there was not enough work for us. After the first three weeks we knocked off into double parties. You have to bear this in mind, that the Europeans working there knew the language, more or less, and could explain the matter to the people, and they did not attempt to interfere in any way with their caste prejudices. We knew what they were, and at the same time while enforcing the law we did what to our minds was right.

18,467. I think some houses were visited every day, and some not more than twice a week?—That is so.

18,468. Which were the ones visited every day?—Those in Hamal Street and Borah Lane.

18,469. At first were the houses in which plague cases had occurred vacated?—No, not in the first epidemic.

18,470. Later when the second epidemic occurred were they all evacuated?—Every one, if a second case occurred therein.

18,471. Had plague at that time become virulent?—There was a most extraordinary difference in the two epidemics. During the house-to-house visitation in the first epidemic you could tell by a man's eyes whether he had the plague or not. In the second epidemic there was often nothing of the sort; there were none of the usual symptoms. There was no furred tongue, and no *facies pestica* in a man's appearance, no swellings in the groin or neck or anything. That was a thing which struck me very much. In the first epidemic I could identify plague at once, although, of course, I am only an amateur.

18,472. Did you find that more people died in the second epidemic or less?—I have not considered that question, but I am quite certain of this, that the third epidemic is much more virulent than the other two. I hope to resume my work again to-morrow.

18,473. Did you find that cases occurred in fresh houses in the second epidemic, or in the houses in which it had occurred the year before?—It was practically entirely confined to those in which the epidemic had occurred the year before; they occurred even in the same rooms. After that the rooms were absolutely stopped from further occupation.

18,474. For how long?—For one month. They were the orders we got from the District Medical Officer.

18,475. Did you find when they were re-occupied after a month that cases occurred in them again?—In one instance only.

18,476. When did the first epidemic end in Lower Kolaba?—Practically a month after we started. We started, I think, in March, and it ended about a month after. We had the whole thing under control then, and there were none but sporadic cases.

18,477. When did the second epidemic begin?—In the following November.

18,478. Was the same system adopted?—No, because we had not the same staff. We did not have the European troops, and we did not have the Native soldiers to assist us, but so far as we could we adopted the same system. I have brought for the inspection of the Commission a photograph of the Staff on the first occasion (handed to President). We had 13 soldiers and a certain number of Native soldiers and some Policemen in the first epidemic; in the second epidemic we did not have them.

18,479. What did you have in the second epidemic?—Nothing but a few Policemen. The rest of the work we did ourselves.

18,480. When did you get Lower Kolaba practically free of plague in the second epidemic?—About a month after we started work. Then I wrote to the Chairman (Sir James Campbell) stating that it was useless to waste our time in Lower Kolaba, because there was nothing to do. I said that he had better transfer the rest of us to Fort Northern where we could do work, and leave four men at Kolaba, which was done. They were quite sufficient; we were so much in touch with the whole district that every man who was engaged on the work knew every house.

18,481. What results have you observed as to the effect of light and air on the disease?—My belief is that it does not matter a bit whether you have light, or whether you have air. I have formed that opinion on three particular houses which were all upper-storeyed houses, in which not a single case occurred on the first, second, or third floor, but in which several people died on the top floor. Of course, the tiles had not been removed, but that is the fact. I have said in my précis of evidence that I cannot understand how otherwise the disease can be anything but air-borne, unless, of course, the unfortunate persons went outside and contracted the disease, and then came back to their homes to go through with it. But that is incompatible with one particular case. There were three barbers living in the same house, one working in the Fort, one at Kolaba and one in Fort Northern. Those three men were perfectly well one night and were dead the next morning.

18,482. Do you know whether it was pneumonic plague or not?—No, that I canot tell you, but Dr. Barry can, because he was there.

18,483. Do you know whether the other inhabitants of the house were in the habit of going to the bazars to earn their living?—Undoubtedly; they were all Ghatis (mill-hands). They all worked in the local mills at Kolaba.

18,484. Was there any plague in the local mills at Kolaba?—Yes; I took two cases out.

18,485. Was there much plague there?—No, I do not think so.

18,486. May it have been that those mill-workers were exposed to less infection than the three barbers; that the barbers may have gone into more highly infected bazars?—One of the barbers shaved nobody but the officers of the Royal Artillery at Kolaba.

18,487. After having had experience of two epidemics what is your general conclusion as to the way in which plague can be overcome?—My opinion is that it cannot be overcome except by the strictest supervision by Europeans—Europeans who know the natives and know their habits and customs. Secondly, if segregation is not to take place, the people must be segregated in their own houses and not allowed to go out, so as to let the plague die out in each house. That is my opinion. I should adopt exactly the same system as they adopted in London during the great plague epidemic in 1666 as related by De Foe. I would lock the house up and not let a single person come out; but I would give them the option of going to a segregation camp if they chose. If you do that you have a chance of stamping the plague out, but not otherwise. It must be remembered that all the people are fatalists.

* Not published with the Proceedings of the Commission.

18,488. If plague is carried by rats how would locking the people up in a house prevent it spreading to another house?—It would die out in time, but of course not so quickly. It must be remembered that these people are not afraid of death in any way, so far as I can make out. What they want is not to be interfered with, and, if they have got to die, to be let die. That is the only way to prevent plague spreading. I have had 20 years' experience of natives in this country, and know something about what their prejudices are.

18,489. (*The President.*) Have you anything else you would like to add?—My evidence has related hitherto entirely to Kolaba. I should like to say with regard to Fort Northern that it is a very much more difficult district to work. In the first place it is not, like Kolaba, a district where you could cordon a certain section and deal with in that way. The inhabitants are of a very different character. Therefore it was not possible to adopt the same stringent measures in Fort Northern as we did in Kolaba. We did not succeed in quelling the epidemic there in anything like the same time we did in Kolaba, but we did it eventually. I submit that if you are going to endeavour to work on the present lines at all you must have a very strong hand, a hand not afraid to carry out measures but at the same time one which is not prepared to quarrel with the people.

(Witness withdrew.)

Mr. A. Britto, called and examined.

18,490. (*The President.*) What are your medical qualifications?—I am Licentiate of Medicine and Surgery of the Bombay University, and Deputy Health Officer C ward, Bombay Municipality.

18,491. I believe you have been engaged in plague operations?—Yes. At present I am in C ward, but at the commencement of 1896 I was appointed to Mazagaon and Tarwadi.

18,492. Have you any information as to the origin of plague in Bombay?—With regard to the first epidemic there is very little information of a definite character, but there is very little doubt that the disease has been imported into Bombay from outside, because prior to the outbreak there was an epidemic at Hong Kong and in Asia Minor. The conditions existing in Bombay are favourable for subsequent outbreaks once the disease has been introduced.

18,493. Do you mean the plague has never disappeared?—Yes.

18,494. There have been recrudescences?—Yes.

18,495. What knowledge have you as to the contagiousness of plague?—Plague is contagious as well as infectious.

18,496. How do you distinguish between the words contagious and infectious?—By contagious I mean by touch, and infectious by introduction into the blood actually by injection.

18,497. What do you say with regard to contagion?—In contagion by human agency, a plague-stricken person acts as a sort of centre of infection by infecting the room or rooms in which he may be moved, and then there is the careless disposal of excretions, chiefly the vomits and the dejecta, all of which contain plague bacilli.

18,498. Do you know if the vomited matter contains plague bacilli?—Yes.

18,499. What is your knowledge about that?—I have not made a bacteriological examination.

18,500. Now, with regard to clothes. What is your knowledge with regard to their being infectious or contagious?—I go on house-to-house visitation, and very often clothes worn by individuals suffering from plague are kept away from us, and these clothes are subsequently used by healthy persons. I really believe the infection is taken by wearing these clothes.

18,501. Do you know any case in which clothes have conveyed infection?—I cannot give you a case, but I can give you a case in which the bedding used by the patient has caused it.

18,502. You withdraw the statement regarding clothes?—Yes. With regard to bedding there was a case at Mazagaon in which the bedding which had been used by the patient was kept by the people; they were not given to us to be destroyed. That bedding was afterwards used, and we had other members of the family who got plague.

18,503. Are you aware whether the other members of the family came in contact with the original patient?—Yes, they did, except the younger members.

18,504. How can you exclude infection by other means? Why do you restrict it to the bedding? Have you any other instance?—No.

18,505. What are you prepared to say with regard to infection?—Infection is taken by wounds and abrasions in the surface of the body and the mucous membrane.

18,506. What is your knowledge about infection through wounds and abrasions in the skin; have you seen cases?—Yes. There have been cases in which people have had slight eruptions. It is not uncommon to see people in Bombay with scabs. Then, also, the natives of Bombay have a kind of eruption which is more of an eczematous character, generally about the loins. I have met with cases of plague in which these conditions existed, that is, the conditions of eczema and scabs, and I have no doubt the infection has been through these.

18,507. Have you had any experience of infection by food?—No.

18,508. Do you know of any case of plague in which the infection was introduced by the digestive system?—I do not know of any direct case.

18,509. What is your knowledge with regard to infection by the respiratory system?—There was a case of pneumonic plague which occurred in a house in the month of August, in the section in which I work. There was one pneumonic case which was concealed from us. Subsequently I found two cases in the same house, one was the manager of the firm, and the other was a woman who was also connected with the firm. Both she and the manager got pneumonic plague. I examined them both at the very commencement, and pronounced the cases to be pneumonic plague. Both of them died. In the case of the manager, one of the attendants subsequently developed plague and died in another house.

18,510. You observed one case of pneumonic plague from which two cases directly proceeded, and then a third indirectly?—Yes.

18,511. How do you know that in any of these cases the plague was introduced by the respiratory passages?—From my observation. The man was lying on a bed on the floor, and was being held by the attendant. The attendant had a little chatty which contained the plague sputum. They generally have a small copper vessel into which the man spits, and this is generally held up to the man's mouth by the attendant. Besides being in such close attendance, it is natural he may have inspired the same air.

18,512. The attendant took plague?—Yes, and he died.

18,513. Might he not have soiled his hands?—Yes; he was holding the patient besides.

18,514. Might not the sputum have been introduced into his own mouth and face by coughing?—Yes, but that would be direct.

18,515. That need not be by the respiratory passages; it might be by the alimentary canal?—If it went to the alimentary canal the form would be enteric.

18,516. Not necessarily. You have had some experience of preventive inoculation, I think?—Yes. When I was in charge of Mazagaon, I made a number of inoculations in company with Major Bannerman, I.M.S., in the most infected centres. This was in March 1897. During the next recrudescence in November up to the end—that is March—I did not observe any cases of plague amongst those who were inoculated.

18,517. How many did you inoculate?—There were about 200 inoculated.

18,518. What record did you keep of those inoculations?—They were in the same locality, and I had occasion to visit them every day in house-to-house visitation.

18,519. For what period did you keep them under observation?—During the time the epidemic raged, which was five months.

Mr. A. Britto.

15 Feb. 1899.

18,520. Did none of those people leave the place during those five months?—No; they are low-class people, and could not afford to leave unless we took them ourselves into camp.

18,521. Did any of them die in that time?—Not to my knowledge, not those who were inoculated, because we directed special attention in cases of plague to observe whether an individual who got plague had been inoculated, and by whom.

18,522. Have you any other 200 people in similar conditions of life and locality who were not inoculated to compare with them?—The contrast was obvious from the fact that we did not get any cases among the inoculated, whereas we did get plague among others living in the same houses.

18,523. Will you give us some examples of that?—There is a place in Mazagaon, known as Telang's property, in which the chawls are very large. In one of the houses there we did as many as 26 inoculations. We had a number of plague cases there, but we did not have one among those persons who were inoculated. There is plague there even now. Another instance is a place known as Bawan's chawl. I do not know the exact number we inoculated, but we did not observe any cases among those, whereas we got plague among the other residents of the place, so much so that the place had to be evacuated, and the people removed to a health camp.

18,524. Are these inoculated people kept under observation now?—I do not know; I am not in charge of the district now. I have been away since June, and am now in charge of C ward.

18,525. You do not know whether they have had plague since?—No.

18,526. Did you make any selection of the persons inoculated?—No, unfortunately we have no choice in Bombay, because the people are very loth to be inoculated.

18,527. You take all you can induce to be inoculated?—Yes. We try and induce them to be inoculated, and then if they consent we inoculate them.

18,528. Even very young persons?—Not very young persons. I have not inoculated babies of one or two years.

18,529. What is the youngest?—Five years.

18,530. If you saw a person obviously unwell, would you inoculate that person?—No, and I would not inoculate contacts.

18,531. Have you given much attention to the clinical study of plague?—Yes, I was in charge of two hospitals in Bombay.

18,532. The symptoms have been fully described in your précis of evidence: have you encountered any symptoms different from the ordinary classic symptoms of plague?—No.

18,533. What do you mean by the cerebral variety?—That variety in which the head symptoms, that is, delirium and coma, are most marked, and where the temperature is not reduced by any treatment—where the temperature rises and the patient dies.

18,534. They are always fatal?—Yes.

18,535. Have they buboes?—No. These cases are rare. I have not noticed any with buboes.

18,536. How do you diagnose the cerebral variety?—First by the facial expression. There is a stolid anxious expression of the face, knitting of the brow, and drowsiness, and then the peculiar condition of the tongue, and the delirium which follows. The cases are rapid, and terminate in death.

18,537. Supposing you had all these symptoms and death did not occur, would you come to the conclusion that they were not cases of plague?—I have not come across any such case, but I should take into account the rapidity with which the symptoms came on.

18,538. What do you mean by the enteric form?—That is where the symptoms simulate enteric fever, but in which the symptoms are more rapid.

18,539. What symptoms of enteric fever are similar?—The first is diarrhœa with the characteristic stool.

18,540. Enteric stool?—Yes.

18,541. Pea-soupy?—Not exactly—yellowish.

18,542. A biliary stool?—Yes.

18,543. Not therefore characteristically enteric?—Not entirely pea-soupy. We do not get any cases of real enteric among the Indians. Then there is great tenderness in the right iliac, tympanitis, and delirium, which goes on from the second to the fourth day.

18,544. What is the form of the temperature curve? Does it resemble the ordinary temperature curve of enteric fever?—I have not noticed the chart very carefully.

18,545. Are there spots?—No.

18,546. What is there in addition which brings them into the category of plague cases?—In some of these enteric cases the mesenteric glands are enlarged.

18,547. Is this observed before or after death?—Previous to death. There is excessive tenderness in the right side.

18,548. The abdomen is generally tympanitic?—Yes but not at the commencement. At the commencement there is gurgling and pain, but not intense tenderness. There is a feeling, though not in all cases, of swollen glands.

18,549. In what region of the abdomen do you feel swelling of the glands?—In the right iliac.

18,550. Then you have specified the hæmaturic variety?—Yes; I only saw one case of that. The man passed bloody urine. Then he got a fit which I put down to uræmic symptoms.

18,551. Was this blood in the urine due to hæmaturia or hæmaglobinuria?—I did not examine by the microscope.

18,552. Have you ever found albumen in the urine of plague cases?—Yes.

18,553. Very often?—In most of the cases.

18,554. Have you seen tube casts?—I have made no microscopical examination.

18,555. Have you made any *post-mortem* examinations?—No, but I have seen the appearances.

18,556. What are the characteristic appearances?—That refers to the position in which the patient lies. We are often called out to see a man who is found dead in the street, and then we have to give our opinion as to whether it was a plague case or not. In the absence of glandular enlargement we look to the position of the corpse; the thumb is generally flexed into the palm, the eye-lids are half open, and the cornea is glistening. Then there is the appearance of the face. There is generaliy a livid, bluish appearance of the whole body. That is how we come to the conclusion that it is a case of plague in the absence of enlarged glands.

18,557. Putting aside the hæmaturic case, have you seen any œdema of the surface in other cases, either after death or immediately before death?—No.

18,558. If there had been œdema it would not have escaped your notice?—It would not have escaped my observation.

(Witness withdrew.)

(Adjourned till Friday next.)

At The Secretariat, Bombay.

FORTY-NINTH DAY.

Friday, 17th February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. M. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. REGINALD GILBERT called and examined.

Mr. R. Gilbert.
17 Feb. 1899.

18,559. (*The President.*) You are a solicitor of the High Court of Bombay?—I am.

18,560. Where do you reside?—I reside in Bandra, a suburb of Bombay.

18,561. What is the population of that suburb?—About 20,000.

18,562. What is the nationality of the inhabitants?—About half are native Roman Catholic Christians.

18,563. When did plague occur in Bandra?—At the end of 1896.

18,564. When did your experience of the plague there commence?—My actual work did not commence till the 12th of February 1897.

18,565. What was the condition of matters with regard to plague generally when you commenced work?—I returned from Australia on that date, and the epidemic was very bad. Many members of the Municipality had left Bandra, and the Municipality was in a state of chaos, and almost bankrupt. I made the following offer to Government, namely, that I should have entire and sole charge of plague operations in Bandra, Government placing in my hands all moneys required, Government to appoint me President of the Bandra Municipality, I not being accountable or responsible to that body for my plague work, but responsible and accountable to Government only. This was accepted. When I commenced work a large number of people had voluntarily left their houses, and were residing in huts in the fields. I at once turned all the people out of their houses and got them to live in huts.

18,566. The whole of the inhabitants of Bandra do you mean?—Nearly all; the better classes did not turn out. Those that lived in detached houses, for instance, all remained in.

18,567. About how many of the inhabitants were included in this evacuation?—About three-quarters of the inhabitants were hutted: certainly more than half.

18,568. About 10,000?—Yes.

18,569. Had you much difficulty in effecting this removal?—Yes. The following extract from a letter which I wrote to the Collector of Thana on the 8th April 1897, illustrates some of the difficulties I had: "I beg "to say that there have been a large number of cases "of plague here amongst persons who have been living "in huts and segregation camps for ten days and "upwards. I believe I have personally taken or "assisted in taking approximately 70 cases of plague "from huts in which the residents have been living "for at least ten days away from their villages. I "think I can at least place the number at 80, and the "only reason why I do not give more is that a large "number of Danda villagers left their camp and went "back to the village, thus getting infected again, and I "cannot safely trust my memory as to what number "of these were taken to hospital. A large number of "native Christians went into huts. These seldom "returned to the villages, and I found cases amongst "such native Christians who have been encamped for "more than a month. One case of a Christian I "especially investigated, as he was taken with plague "at least 14 days after removing into a segregation hut. "The only way he could have got the contagion was "when he went into Danda with his bullock cart and "removed furniture from the houses of infected people. "I should mention that in many of the above 80 cases "the camps were very dirty, and the fæces of those "encamped there were often quite close to the huts. "On one or two occasions I found persons affected "with plague engaged in making chappattis for the "family so as to distract my attention. So often has "this trick been practised on me that I make a "habit of examining very carefully persons engaged "in cooking when I am doing inspection work. I was "not aware that anyone dare allege now that the "disease is not communicable by contagion. I am not "a medical man, and only give my views with great "deference. I have formed a strong opinion upon the "matter, and that is the disease is very contagious at "first, and less so afterwards; that people who live "in upper storeys escape it most; that it is most contagious in houses which are free of ventilation. I "also believe that those who sleep in very open places "will never catch it." I had great difficulty in getting the people of Danda, a village of about 3,000 fishing people, to turn out. They suffered very badly from plague. They abandoned their dead, and would not assist in their cremation. They also left children with their plague-stricken or dead parents. I had a hospital shed built and properly equipped with a proper staff. Most of the native Christians voluntarily came to hospital at first, but afterwards they concealed their cases. This was, I believe, because so few lived. A few Hindus came voluntarily and one or two Muhammadans. The rest we had to take by force.

18,570. What do you mean by taking them by force?—Actually taking them by force.

18,571. By what instrumentality?—I had to do it myself once or twice, and I had orderlies and police.

18,572. Police and soldiers?—Yes, I had two or three native soldiers with me, and also the Municipal Inspectors and so on.

18,573. What was their opposition due to?—They would not come, so we had to take them on charpoys, or something.

18,574. On what grounds did they oppose the removal?—They thought they were going to be poisoned, and they objected altogether to going to hospital. They believed we intended to poison them, and in many instances they would take no food or drink, or any medicine whatsoever. We had one case of a little Hindu boy who lived for many days, and I believe would have recovered if his parents would have allowed us to give the child food, stimulants, and medicine. They would not yield to all the persuasion we showered on them. Bandra is surrounded by fields, and it is easy to find places for the people to camp out. By the end of April 1897 plague was virtually stamped out of Bandra. I reckon nearly 1,000 people died from it.

Mr. R. Gilbert.
17 Feb. 1899.

18,575. How long did you take to effect this evacuation?—A great deal had been done voluntarily between Christmas and the 12th of February, when I took charge. Directly I took charge I would not allow anybody to stay in. They all went out—virtually all of those that lived in huts or houses that were crowded.

18,576. How long did it take?—Some were out before the 12th of February, when I took charge. It was then about its highest point. I might mention the following facts. A native family was camped in the fields in hut A for upwards of five weeks free of plague. A case of plague occurred on the 31st March, which they concealed and placed in a small hut B, 50 yards off A. This case died 31st March 1897. Huts A and B were burnt, and the family moved to hut C. On 4th April another case occurred in hut C, and the family erected a fresh hut D, to which they moved. On 9th April another case occurred in hut D, and the family moved to hut E. No further cases occurred. Everybody was out by the middle or end of February, and then by the end of April plague had disappeared from Bandra.

18,577. Can you tell us how many cases of plague had occurred before the end of February?—It would be difficult to say with accuracy, because there was no record kept. Most of the people had absconded. The Municipal staff had run away, and there are no proper statistics which we can go on. I could find out by writing to the Municipal authorities at Bandra, and ascertain how many died previous to the 12th of February.

18,578. Will you do so?—Yes. (Note by witness on correcting the proof of his evidence:—I am sorry to say I have not been able to secure this, and figures are not reliable made at this time, as most of the staff had run away.)

18,579. After the evacuation had been effected how many died?—Quite half, certainly.

18,580. Half the total?—Yes, quite half. I am speaking from memory, but I believe there were more than that, because plague had not got to its height when I took over charge; it was worse for a little time.

18,581. At what time after the evacuation had been effected?—It gradually began to cease when I got them into huts. Of cause cases often occurred in the huts, and so I pulled down those huts, and made them go out and build other huts somewhere else, and the plague gradually lessened.

18,582. Did the number of cases commence to fall rapidly after evacuation had been effected?—Yes, soon after the evacuation. Of course I used to take it village by village. One or two villages did not get plague at once, so I did not move the people out where there was no plague. There are small hamlets at Bandra—small collections of huts, and I never disturbed people unless plague broke out in them. I can give you one notable instance. I found about 200 Mahars living in huts, and on the first day, the 12th of February, plague broke out, and I found a corpse there, and one other person with plague. I had them all out, and hutted, that afternoon. I gave them some material which was handy to build huts, and they were all out by the afternoon. They were absolutely free from plague for the rest of the time. I camped them close to the sea shore.

18,583. That was a very rapidly effected and successful evacuation?—Yes. I have also other cases.

18,584. But the evacuation was not so complete as in this case?—No, not so complete as this one, but I think this was because they were under better control than the others.

18,585. What is your opinion about the value of evacuation and segregation from the experience you have had?—I think it is very successful in small places, but it would be absolutely useless in Bombay.

18,586. What is the maximum population which you think can be moved out?—If you have a town with open country all round, where you can make the people go out, I should not like to say what the limit might be.

18,587. It might be a very large number?—Yes, but in Bombay which is surrounded by sea on all except one side, there is no place to do it, and it would be absolutely foolish to try it, in my opinion.

18,588. You had a good deal of experience in regard to inoculation, I think?—I fought the question very strongly here. I am very much in favour of it.

18,589. Can you tell us what your actual experience of inoculation has been?—I have no actual experience, except more than an intelligent man who reads statistics.

18,590. You had no direct experience?—I was inoculated myself, but it was not done largely in Bandra.

18,591. Your opinion is founded on what you have read?—Yes, and what I have seen of it here.

18,592. And did that lead you to form the opinion that it was a valuable measure for restricting plague?—Yes, I consider it a most important thing.

18,593. Have you got any example which came under your personal observation, in which you found it was very beneficial?—No, none at all.

18,594. Have you found any difficulty in inducing people to be inoculated, or have you had an opportunity of observing whether there was a difficulty or not?—I have not tried it, and I have had no experience. In the little experience I had the people were against it.

18,595. As much against it as against evacuation?—Yes, quite as much, but it was never worked properly.

18,596. (*Dr. Ruffer.*) When you were in charge of the plague operations in Bandra did you have a medical man to advise you, or were you in sole charge?—I was in sole charge, but there were several medical men who assisted me as volunteers.

18,597. Native medical men?—Two natives and a European; they were all volunteers.

18,598. What provision had you for disinfection at Bandra?—I went in for it rather largely. I had a staff of seven men in the Royal Artillery, and I had some native inspectors, and I thoroughly disinfected most of the houses; for instance, at Danda I did every single house. The disinfectant I used was perchloride of mercury.

18,599. In what strength?—I forget now, but it is the same strength as was used in the Hong Kong epidemic. A plague doctor from Hong Kong advised me as to the strength.

18,600. Did you disinfect the clothing of people before they were moved into camp?—No, I did not.

18,601. When you had a plague case in camp did you disinfect the clothing of the people?—No, we had not time.

18,602. What was the staff in your hospital?—I had two European nuns, and two or three native Christians who came from the Bandra Convent, also several native hospital boys, a Hospital Assistant, a compounder, and sweepers. It was very well equipped.

18,603. What was the maximum number of patients you had?—We had altogether in hospital about 150.

18,604. The other cases died in their houses?—Yes, we often found them dead.

18,605. You say in your précis of evidence, "I reckon "nearly 1,000 people died from plague at Bandra"; how did you ascertain that number?—I can give you the official numbers, but they are incorrect.

18,606. Why are they incorrect?—They are incorrect in this way, because I used to take the normal. The normal death-rate in Bandra is one or two a day, and all over that I consider were plague. As a matter of fact, there were officially 800 returned as having died of plague, and I found that that was not correct.

18,607. You also say, "I think in small towns plague "can be stamped out by segregation and evacuation"?—Yes.

18,608. On what evidence do you base that statement?—On practical experience of my own.

18,609. Can you give us an example of that from your own personal observation?—For instance, plague left these people so soon after I turned them out.

18,610. How long after you turned them out?—It began to decrease gradually, and then it disappeared.

18,611. How long did it take to disappear?—It had all disappeared by the end of April. Of course it is difficult to say, as there were two or three hundred huts, and cases kept occurring in the camps.

18,612. It may have gone on much longer than you think?—When they were turned out it left them, it got gradually less, and by the end of April it virtually disappeared. There were only a few cases after the

end of April, but I do not say they were all in the camps, because at the beginning of May I let the people go back.

18,613. And did the epidemic grow?—No, then cholera came.

18,614. Can you give me some information about quarantine regulations at Bandra?—People were not allowed to come in except with passes, and then when they got out at Bandra they were stopped on the causeway and they were examined at the railway station.

18,615. How did you prevent people coming in without passes?—That was done by the Plague Committee.

18,616. You have no information about that?—No.

18,617. Do you think people got in?—Oh yes, it was a mere question of getting a pass, and they were allowed to go in. People passing over the causeway were examined by a doctor, and were allowed to pass in.

18,618. Do you think the people passed in unknown to the authorities?—I have no doubt they did.

18,619. And you think people got out?—Yes, I am sure.

18,620. How many people did you inoculate at Bandra?—I believe there were only about a couple of hundred done.

18,621. Do you know how many died?—I do not think any died.

(Witness withdrew.)

Prof. T. K. Gajjar called and examined.

18,622. (*The President.*) You are a Professor of Chemistry?—Yes—Professor of Chemistry at the Wilson College.

18,623. (*Prof. Wright.*) You have formed some views, have not you, about the causation of plague?—Yes, I have.

18,624. Would you explain your views to us?—In the first paragraph of my précis of evidence I say that the origin is due to a combination of two causes—the presence in the air of germs, and the presence of environment. When these two are combined, plague breaks out. I have got several statements giving authorities.

18,625. Do you think these germs are of a specific nature; do you think that a particular kind of germ is necessary?—They must be of a particular genus of cocco-bacilli.

18,626. What sort of cocco-bacilli must be present?—Of a certain morphological shape.

18,627. You think they must be short rods?—Yes, in a way.

18,628. Do you think any short rod-shaped bacillus will develop into a plague germ?—I am not sure of that, but it must be of a particular form as well. The germs are generally styled species; but in the same species you might have pathogenic germs and non-pathogenic germs, or saprophytic and parasitic.

18,629. In the classification of bacteria which is generally adopted, do you not think that the physiological properties are taken into consideration as well as the morphological shape?—Yes.

18,630. You do not differ from ordinary bacteriologists in this matter. You think with them that the plague germs are bacilli which have a particular shape, and which are endowed with certain special physiological properties?—No, I do not think so. They are not endowed with specific and constant characters. If we accept the general view of the "species" of germs, even then there is a variation in the same "species." When we say there is a "species" of germs which we call plague germs, in that "species" will lie, as well, germs of a non-pathogenic nature and germs of different degrees of pathogenic virulence.

18,631. What are the circumstances that you think gave virulence to the bacteria?—The environment—the media.

18,632. You think, then, that, in addition to the germs, some other influence must be at work to produce plague. What environment do you think is necessary; do you not think that a plague germ of sufficient virulence will infect an animal in any part of the world?—Yes, that is what I think.

18,633. You mean, when you have a weak and attenuated germ, some further circumstances are required to cause the development of plague?—Yes.

18,634. What kind of environment do you think is required?—Some filth.

18,635. You think, under filthy circumstances, the bacteria acquire more virulence?—Yes.

18,636. Do you think that they require certain other conditions?—Yes.

18,637. You have, in your précis, laid some stress on temperature and moisture of the air?—Yes.

18,638. Do you think that plague bacilli flourish most luxuriantly when the air is moist?—Yes.

18,639. Can you account for the fact that plague bacilli do not flourish in Calcutta, where there is both moisture and filth, while they flourish in Bombay?—The sewage decomposition may not have reached the particular stage we have it in Bombay.

18,640. I understand that Calcutta is extremely filthy, and that the smells are extremely bad, and that in that respect Calcutta is worse than Bombay. Have you any theory to account for the fact that plague is very active in Bombay and very quiescent in Calcutta?—Either germs of a sufficiently virulent degree may not be present in Calcutta, or the particular stage of decomposition may not have been reached, although it may appear very filthy and very foul. Further, we do not know what particular products and gases of decomposition are necessary for this purpose. Unless we analyse the air comparatively, we cannot determine that.

18,641. Then a combination of sewage decomposition and of germs is not by itself sufficient to cause an epidemic. Is that your opinion?—Sewage decomposition of a particular kind at a particular stage can develop plague in combination with germs in a particular stage of evolution.

18,642. Are you able to be more precise about this; can you say what particular kind of sewage decomposition is required for the development of plague? For instance, can you explain how it is that the sweepers who carry away the ordure of Bombay suffer very little from plague, although they come in contact with every kind of sewage?—Decomposition of long-standing sewage matter on a sufficiently large scale, leading to the evolution of such poisonous gases as carbonic acid, sulphuretted hydrogen, ammonium sulphide, and different toxic amines in a concentrated form would be necessary for developing plague. The sweepers acquire immunity from being accustomed to work in filthy surroundings; their immunity is due to that fact.

18,643. In view of the great sewage pollution which exists in Bombay, do not you think that everybody in Bombay must have acquired such immunity?—I do not think all people live in such surroundings.

18,644. But all the people who live in filthy surroundings would have acquired this immunity, would they not?—Their occupations are not such, and the surroundings in which they live are not habitually such as the sweepers are brought to in their work. They were not exposed to such filthy conditions before the evils of the sewage system were developed, I am glad to say.

18,645. You say that sewer gases probably exert an influence on the development of plague. One of the arguments you adduce for that is that more "attacks of plague" occur at night?—Yes.

18,646. What do you mean by "attacks of plague;" do you mean people begin to sicken of plague during the night?—Yes.

18,647. Have you any statistics to show that people come into the hospitals more at night than in the daytime?—They are not generally sent to the hospitals at night; they are sent during the daytime.

18,648. What evidence can you adduce of the fact that people begin to sicken of plague during the night, and not during the day?—In the localities with which I am acquainted I heard of more attacks at night; and if you require a statement, I will furnish a comparative

Prof. T. K. Gajjar.

17 Feb. 1899.

statement, where information of night-attacks was obtained, and information of attacks during the day.

18,649. Have you evidence on that point, sufficient to satisfy you that more people begin to sicken of plague at night than in the daytime?—Yes, I am satisfied. Further, I have got several statements ready in support of the view I put forward. It is not an original theory; it is the pithogenic theory of Murchison. I am not here to suggest any new theory, such as the millet theory of Dr. Waters.

18,650. You have expressed yourself dissatisfied with the antiseptics at present in use—mercuric chloride, for instance. Do you doubt that mercuric chloride will kill germs?—Yes, I doubt that.

18,651. Have you made experiments on that point?—I have not actually experimented with plague bacteria.

18,652. Have you made experiments with other bacteria?—Yes.

18,653. Have you found that bacteria can grow in mercuric chloride solution?—No, because they are rendered inert, inasmuch as an insoluble casing is formed by coagulated albumen.

18,654. What is the albumen which becomes coagulated?—If the germs are in an albuminous medium, the albumen will be coagulated by the action of mercuric chloride, and this coagulated albumen will protect them.

18,655. Eggs, I understand, consist of albuminous material. If you introduce an egg into mercuric chloride, and if you thereby coagulate it, do you not take away its vitality?—Yes.

18,656. Does not the same thing, then, hold true of an albuminous microbe?—Yes.

18,657. Why do you think that the microbe retains its vitality in mercuric chloride solution?—The albuminous medium in which bacteria are held is attacked first, and precipitated, and thus the destruction of bacteria is prevented.

18,658. Supposing they are held in suspension in water?—Then they would be destroyed; but if they are in an albuminous medium they will not be destroyed.

18,659. You do not think bacteria will be killed if mercuric chloride is applied to a wall?—In such circumstances it would act.

18,660. If mercuric chloride solution was poured on a floor which contained bacteria, you do not doubt, do you, that it would destroy the bacteria?—It would, in the absence of albuminous material; but it should not be used in the ordinary brass or metallic syringes.

18,661. That is another objection?—Yes.

18,662. You do not doubt that these disinfectants have bactericidal power?—No, they have this power, provided no albuminous medium interferes.

18,663. You have an objection to Prof. Haffkine's vaccine?—Yes.

18,664. On the ground that bacteria in the vaccine are not dead, but dormant?—Yes.

18,665. I understand that you think the vaccine contains living plague microbes?—Yes, in a dormant state.

18,666. Have you taken steps to ascertain that it actually does contain these living plague microbes?—Yes, I have. I went to Prof. Haffkine's laboratory several times for the purpose. I was introduced to him a month back, and I was discussing the question with him. Prof. Haffkine calls them dead, inasmuch as their cultures in artificial media are found extinct. He has not satisfied me that they cannot crop up into activity in living animal systems.

18,667. You have, in your précis, made an assertion that the bacteria are still alive in the vaccine. What is the evidence upon which you base that statement?—The process adopted is not sufficient to kill bacteria.

18,668. What is the process adopted?—The serum is heated to about 50 or 60 degrees.

18,669. We have it in evidence that the fluid is heated to 65 degrees for an hour. Does that not suffice?—There are certain microbes that are not killed at that temperature.

18,670. Do you know as a fact that plague microbes are not killed at that temperature?—No, possibly they are not.

18,671. I thought you had made yourself responsible for the stronger assertion that the plague bacilli were actually alive in the vaccine?—Yes, alive in a dormant state. There are other circumstances also confirming this belief. The only explanation of propagation and communication by inoculation could be given only on the supposition of microbes not being killed.

18,672. What is the other evidence that makes you think the plague vaccine contains living plague germs?—The symptoms we observe in inoculated persons. There is a period of incubation.

18,673. What is the period of incubation?—About six hours or one day.

18,674. Do you mean that the symptoms which are produced by the vaccine do not come on for six hours?—Yes, the fever of inoculation; there must be some living microbes, and they would multiply.

18,675. That is how you explain the fact that six hours elapse before you get any symptoms?—If it was merely a toxine, or a chemical substance, the symptoms would probably supervene within an hour two.

18,676. Do you think that if you put a slowly soluble poison under the skin, you would have symptoms developed immediately?—I am talking of a readily soluble chemical substance.

18,677. Are you aware that the toxines which are contained in Haffkine's vaccine are not all in solution in that vaccine? Are you aware that many of the toxic substances are contained in the bodies of the bacteria? Do you think this fact might not readily account for the slow supervention of the symptoms of poisoning?—You mean they are insoluble?

18,678. Do you know what the contents of Haffkine's vaccine are?—Yes, they are the supposed dead germs and toxines.

18,679. Dead germs, I understand, require to be dissolved before their constituent substance could exert a poisonous effect on the system; is that so?—The so-called "dead" germs will act, without being dissolved, on their enveloping casing being dissolved.

18,680. Do you think that solid particles can act poisonously without being dissolved?—If the germs are dormant they might grow and multiply.

18,681. I understand that you think that the germs are living, and that the poisons are introduced in a soluble condition, and that it is therefore not a question of their requiring to be dissolved?—No, but if you separate the serum into two portions, we find that the supernatant fluid gives all the febrile symptoms. That is what I find in Prof. Haffkine's own statement.

18,682. I think we had it from Prof. Haffkine that he had not made experiments on the effects of the supernatant fluid alone?—I have got it here. The sediment is the cause of local inflammation, and the supernatant fluid is the cause of febrile symptoms. I find it in Dr. Bhalchandra's printed lecture, at page 4.*

18,683. Have you got your facts from Prof. Haffkine?—In my conversation I got this very explanation.

18,684. Have you any other reasons beyond the fact that the advent of the symptoms is delayed for six hours, for thinking that Prof. Haffkine's prophylactic contains living plague germs?—Yes; the communicability—the increased mortality among the uninoculated.

18,685. What evidence have you of increased mortality among the uninoculated?—The published statements of Prof. Haffkine show that uninoculated died in very large proportions, and such was not the case in any town where inoculation was not introduced.

18,686. Will you give us an instance? I think you refer to the case of Dharwar and Hubli. Do you know what the total mortality among the uninoculated was in those towns? What, for instance, was the total mortality in Hubli among the uninoculated?—I have not got the total.

18,687. Would you be surprised to hear that the total mortality among the uninoculated up to December was only 14 per cent.? Have you added the figures up?—No, I have not added the figures up. I think that is high enough.

18,688. Do you think that the 14 per cent. mortality which occurred among the uninoculated in Hubli is a higher percentage of mortality than has occurred in other places?—Yes.

* Not published with the Proceedings of the Commission.

18,689. Would you be surprised to hear that in villages round about Hubli where no inoculation had been done, mortality amounted to 28, 29, and 30 per cent.?—I am told several people went to Hubli to get themselves inoculated.

18,690. That is quite true. The total mortality among uninoculated in Hubli, which you said established your case, was 14 per cent. We have had it in evidence that round about Hubli, in the villages, mortalities of 28 per cent. were not uncommon where no inoculation was done. How does that agree with your theory that inoculation causes increased mortality among the uninoculated?—You are citing villages round Hubli, and there inoculations were performed.

18,691. We have had it in evidence that no inoculations were performed in the villages which are in question?—Captain Leumann states in his report* that he inoculated several hundreds and thousands coming from different villages round Hubli.

18,692. Do you think there is no greater mortality than 14 per cent. has been observed to occur from plague?—Sometimes it may be. I have not come across any instance of higher mortality in places untainted by inoculation.

18,693. Do you know what the mortality was in Dharwar among the uninoculated? You say there was an extraordinary high mortality; would you be surprised to hear it was 9·5 per cent.? The facts which you have in view are, I understand, the data which refer to the individual weeks. Those facts were taken upon a census of the inoculated and uninoculated, and you think there was a large mortality among the uninoculated there?—Yes, I would be; because the Government Weekly Returns show a much higher rate than 9·5 per cent. This higher rate can be reduced to any extent by simply distributing the mortality over long periods.

18,694. Have you any evidence that the numbers of uninoculated are correctly given in the weekly report?—Approximately they must be true.

18,695. How do you know?—They are the census returns.

18,696. You cannot vouch, can you, for the accuracy of the figures of uninoculated given in the weekly returns?—They are supplied by Government Officers.

18,697. You have not totalled the figures up to find out what was the mortality among uninoculated in a sequence of weeks; the total as thus arrived at is very low, is it not?—Of course, the extraordinarily high mortality of those weeks during which inoculations have been performed in very large numbers, may be disguised by totalling up and taking the mean.

18,698. Have you totalled those figures up?—No, I have not totalled them up. The results arrived at by totalling would fail to give an idea of the true state of things. When the numbers of inoculated increase rapidly, we find the mortality percentage increasing.

18,699. Does it occur to you that many inoculations were performed where plague was very virulent, and that a large mortality of plague causes a large afflux of people to the inoculation stations?—The inoculations at Dharwar and Hubli were more or less of a compulsory character. There a rise in the epidemic did not lead to a rise in the inoculation figures, but the inoculation was the cause of the rise of the epidemic. I will give you an instance of Daman.

18,700. Where did you obtain your facts about Daman?—I have Prof. Haffkine's Report† here.

18,701. Would you tell us the facts that strike you about the mortality in Daman? What do the facts you propose to quote purport to show?—An increase of mortality among the uninoculated.

18,702. An increase as compared with what?—Compared with stations where no inoculations were introduced.

18,703. You mean there was a larger mortality in Daman among uninoculated than in any other place in India. Before you give us your facts, will you tell us what your facts are going to prove?—That an increase in inoculations produces an increase in mortality among the uninoculated.

18,704. Do you not think where an epidemic is severe more and more people would naturally offer themselves for inoculation?—How can such conservative people of this country know it for certain that inoculation would save them, and rush to avail themselves of such a novel and experimental measure? When an epidemic is violently raging they would, on the contrary, refuse to oppose the decrees of such a visitation of the Plague Deity.

18,705. If the epidemic increases in severity, do not you think that that increase will cause more people to be inoculated?—The epidemic cannot increase so very rapidly. In Hubli there was a jump.

18,706. Would you tell us the facts which you are going to give about Daman, and what they are going to prove?—Whenever inoculations were done, the mortality, which was on the decrease, jumped up. Twice it has been the case at Daman.

18,707. Would you prepare a table showing these facts, and send it in to us for a consideration?—Yes, the table is as follows:—

The number of inhabitants in Lower Daman were 10,900. Plague first appeared there in February 1897. In February and March nearly 2,000 people left the city, a cordon was established on the 23rd March, and the British territories were closed on the 30th March.

The First Series of Inoculations.—Between the 23rd and 25th of March 1897, 846 persons were inoculated, and 171 more between the 4th and 7th of April.

This was followed by the *worst period* of the epidemic. The climax was reached in the middle of April, the daily mortality rising to 80.

The Second Series of Inoculations.—529 persons were inoculated between the 17th and 27th April, and 99 more between the 24th April and 2nd May. It may be noted that these inoculations also had the effect of raising the mortality, the number of deaths on the 30th April being 38, and on the 4th May, 47.

The mortality began to decline in May, and dropped down to 6 and 8 on the 17th and 18th May.

18,708. You had two reasons for saying that bacteria were alive in Haffkine's fluid. One was that the symptoms do not appear till after an interval of six hours; the second reason you gave for your belief was the fact relative to the mortality among the uninoculated in Hubli and Dharwar. You now add Daman. Have you any further reasons for your belief?—Inoculation was also tried at Undhera, a village in the Baroda territory.

18,709. What was established by the experiments in Undhera?—All the deaths among the uninoculated took place within a week or so after the inoculation.

18,710. Does it occur to you, if you vaccinated against small-pox, and a small-pox epidemic was going on, you would not get your immunity immediately?—It may be so. But I am not referring to deaths among the inoculated. The many deaths that took place among the uninoculated were within a week or so after the inoculation, and although the uninoculated remained uninoculated, there were no deaths afterwards. The epidemic practically ceased after a fortnight after inoculation date.

18,711. You say all the deaths occurred among the uninoculated?—I say all the deaths among the uninoculated took place within a week after the inoculations were introduced—most of them, I do not say all; there were some few deaths after the first week or fortnight.

18,712. What do you deduce from that?—That there must be some connection between inoculation and the spread of plague.

18,713. Could not you account for the facts just as well by referring them to the epidemic that was raging at the time?—It could not rage in this particular way—that it goes up to its climax when the inoculations are in the highest proportions. I have noticed in several instances that when the number of inoculations was largest the epidemic was at its climax.

18,714. Would you pass on from that question. Have you any other reasons than those you have given us for thinking that there are live germs in the vaccine?—Yes, I have got several other facts. There are many houses in Bombay where no plague cases occurred before or after inoculation; but there were some cases just after the inoculation.

18,715. Does that prove that these cases were referable to the inoculation?—I think that these cases should be

* *See* App. No. XV. in Volume I. of the Proceedings of the Commission.

† *See* App. No. IV. in Volume I. of these Proceedings.

Prof. T. K. Gajjar.

17 Feb. 1899.

referred to inoculation. There are many such occurrences.

18,716. If there was a wedding in a house, and a case of plague occurred afterwards in that house, would you infer that the wedding would have produced the plague?—It is not like that. This causal connection can be explained on a scientific basis.

18,717. You say that the facts compel to this conclusion. I say that a similar train of reasons would also compel you to the conclusion that the wedding in the house was the cause of the plague. You have an inoculation in a house, and a case of plague in another inhabitant of that house, and you argue that the case of plague is due to the inoculation. That is your argument?—That is not my argument.

18,718. Will you, then, state your argument?—I have reasoned this out on a scientific basis, and I have corroborated it by statistical data.

18,719. The facts, you say, force this conclusion upon you, that when an inoculation is performed upon one person, some other person in the house gets plague. Is the evidence you adduce any more conclusive than the evidence that can be adduced to prove that a wedding in a house is necessarily followed up by a case of plague in that house?—If there were a lakh of weddings followed by plague in every instance, I should certainly take it upon myself to see if any connection could be traced on a scientific basis.

18,720. But you did not say you had a lakh of cases in which inoculations in a house were followed up by the occurrence of plague cases; you said that there were *some* houses in which that sequence had been observed; have you made a census of those houses?—I have got it, but it is not complete. But, as far as it goes, it is sufficient to convince any reasonable man.

18,721. Have you any more *such* arguments which you wish to adduce in favour of your views that the inoculations are a source of danger to the uninoculated?—In Hubli we find that there was an increase in total mortality. That is another way of looking at the same figures. The increase of the total mortality increased with the number of inoculations.

18,722. I asked you whether you thought that inoculation would not increase *pari passu* with the growth of an epidemic. Is not that the natural way to look at it? The more the danger from plague, the more the people would recur to inoculation. Is not that a simpler way of explaining these facts than that which you adopt?—The epidemic would not keep *pari passu* with the inoculations.

18,723. Do you think the vaccinations would not keep pace with the rise of an epidemic? Do you think if the mortality from plague to-morrow in Bombay was 1,000, and the day after that 2,000, that more people would not recur to inoculation?—No, I did not think so.

18,724. Do you think that it is the danger of being attacked by plague which causes people to come for inoculation? Do you think that if an epidemic of small-pox breaks out, it does not drive people to vaccination?—No. If it is produced by the vaccination, people would not come in for inoculation.

18,725. If what is produced?—If the rise in the epidemic was due to vaccination.

18,726. How do you know that? There are two explanations, either that the epidemic produces vaccination, or vaccination produces epidemic?—You mean to say the epidemic and the inoculation went up in the same proportion?

18,727. That is the fact which we have to explain. As plague increases, inoculations increase. You have that in every case of epidemic. For instance, when there is a large epidemic of small-pox, people get vaccinated in large numbers. Do you think that vaccination produces an epidemic of small-pox, or that the epidemic of small-pox produces vaccination? You think, do you not, that vaccination is effective in stopping small-pox?—Yes, I think it is.

18,728. Let us pass on to the question of iodine terchloride, which you mention in your précis. You have an idea that the antiseptics in use are useless?—More or less.

18,729. That they are useless therapeutically, I mean?—Yes.

18,730. You think the terchloride of iodine would be a better antiseptic than any of those which are at present in use?—Yes.

18,731. In support of this opinion, you can produce data showing that one in 1,000 of this terchloride would kill bacteria in a body?—Yes.

18,732. Have you calculated how much iodine terchloride would be required to produce a concentration of one in 1,000 in the body? What doses would you have to give to effect the destruction of microbes in the body?—Doses of 20 minims repeated every hour.

18,733. I have calculated it out, and I find that an ordinary man weighs 70 kilos, that is, 70,000 grammes: a concentration of one in 1,000 would only be obtained by administering to him 70 grammes of iodine terchloride?—Yes, if you would include also bones, muscles, &c. in your weight.

18,734. Seventy grammes is 2½ ounces. What is the sense of giving a dose of 20 minims when you want 2½ ounces to produce a bactericidal effect?—If we take the weight of the blood only, the quantity required would be 5 grammes to produce the full germicidal effect in one single dose; but we cannot give such large doses; but small doses will exert inhibitory action.

18,735. Have you any evidence to show that?—I have several letters with me in the vernacular to say that they used this, and that people were cured of plague in Belgaum, and other infected places.

18,736. You have two cases where marvellous effects were, you say, obtained in the Parsee Hospital. Do you think many marvellous cures are not effected also by Mother Siegel's Syrup?—That was the opinion of a medical man of a very good reputation.

18,737. Most medical men attribute marvellous results to most drugs?—I do not know. The late Dr. Bahadhurji tried many experiments, and Prof. Behring also used it. Iodine terchloride is his favourite drug.

18,738. This iodine terchloride was not discovered by you; it was discovered, was it not, in Germany?—Yes, it was.

18,739. Do you know whether it is used in the treatment of fevers in Germany?—I do not know that. It is used in dyspepsia and flatulence, and in diseases of gastric fermentation.

18,740. I am speaking about fevers. Did its inventor recommend it as a therapeutical agent which was applicable to the treatment of fevers?—It is on trial there. Prof. Behring uses it in diphtheria. I have got a standard authority for this information, namely, Stephenson and Murphy's Hygiene.

18,741. Are you aware that Prof. Behring, so far from prescribing iodine terchloride as a cure for diphtheria, has brought out an anti-toxine as a cure for diphtheria? If iodine terchloride was effective in diphtheria, do you think that Prof. Behring would have taken the trouble to seek out a new therapeutical method for diphtheria?—It is stated in the standard books. He is using it along with his serum for germicidal purposes.

18,742. (*Dr. Ruffer.*) You say that one of the arguments against using Haffkine's prophylactic is that there is a long incubation period between the time of injection and the first symptoms. Supposing you inoculate an animal with a small quantity of snake venom, how long is it before the first symptoms appear?—Probably an hour or two.

18,743. Are you aware that sometimes it takes as long as six or seven hours? I will take you to another point. I believe naphthaline is not a bacterial poison?—But it is an insoluble substance.

18,744. It is, but supposing you give an animal large doses of naphthaline, the animal goes blind after a time, does it not?—Yes, but it will take some time. I do not know how long.

18,745. You may take it from me that it takes several days; months even?—It is a most difficult substance to dissolve.

18,746. Are you aware that all bacterial toxines require a long incubation period before they act? Supposing you take a tetanus culture, and filter off all the bacteria, and inject the pure toxine into an animal, how long does it take before the first symptom shows itself?—From the authorities I find that these symptoms

must take place in an hour or two if the toxines are in a soluble form.

18,747. My experience is that it takes at least eight or ten hours, and that if you give an animal a thousand times the dose that would kill the animal, you see no symptoms for seven or eight hours. Supposing you inject a filtered culture of diphtheria toxine, how long is the incubation period?—I have not studied all these toxines.

18,748. I simply point them out.—You mean there are incubation periods for toxines.

18,749. Do not the bacteriological facts we know absolutely prove the opposite of your theory?—I have Klein's authority to prove that toxines should act within an hour or so, while sometimes Prof. Haffkine's fluid requires a day.

18,750. Does not the fact that a poison takes a long incubation period simply show that it is a bacterial poison?—Yes.

18,751. (*The President.*) Have you anything else you wish to lay before the Commission?—I have a chart here* showing the barometrical pressure and plague mortality. The mortality goes *pari passu* with the rise in barometric pressure. That explains that environment (the sewer gases) has much to do with the plague. In summer we find the barometric pressure very low, and then the soil and sewer gases do not come up; while in winter, when the barometric pressure is at its highest, the warm moist gases come up. Owing to these emanations the germs acquire their pathogenic functions, and the virulence is greater.

18,752. Have you taken into account the fact that in cold weather people crowd into their rooms, and that, therefore, infection may be greater?—Crowding is rife throughout the year.

18,753. But it is greater in cold weather?—Yes, people shut up their windows and doors, but then that probably explains my theory as well, that gases are accumulated in those places, and that the air is injurious.

*Not published in the Proceedings of the Commission.

(Witness withdrew.)

Mr. W. C. Shepherd, I.C.S., called and examined.

18,754. (*The President.*) I believe you are Assistant Collector at Thana?—Yes.

18,755. Have you acquired your plague experience entirely there?—Yes.

18,756. What is your experience with regard to the source of infection?—Generally in Thana, as far as I have been able to make out, the source of infection has been some infected person coming from Bombay.

18,757. You think it has been carried by human agency?—Generally by human agency; but in some cases rats appear to have died before any case occurred in the village.

18,758. In some cases it has been introduced into the locality not by human agency, but by rats?—It seems so in one or two instances.

18,759. How far have rats proceeded from the nearest infected area in the cases you have referred to?—There was one case in which the nearest infected area was certainly three miles away, possibly four.

18,760. Can you entirely exclude human agency in that instance?—No, I could not in any instance. Our information was so inaccurate at the beginning of the epidemic that I could not lay any stress upon it. I do not know anything about the way rats travel. I believe they travel long distances.

18,761. There are, at any rate, human conduction and rat conduction?—Yes.

18,762. Have you any evidence with regard to the way plague can be conveyed by clothing or dead matter?—No.

18,763. I think you have had a good deal of experience with regard to plague measures?—Yes.

18,764. Firstly, with reference to evacuation, what is the opinion you have formed from your personal experience?—In every instance where evacuation has been carried out the plague has afterwards decreased. The effect of evacuation appeared to depend upon whether it was immediate or whether it was delayed. When it was delayed the plague mortality was greater than when it was carried out immediately.

18,765. Will you give us the number of cases before total immediate evacuation, and the number after; also, if possible, the number which occurred 10 days after evacuation, so as to exclude those who had been already infected?—(Witness subsequently explained that he could not give any reliable statistics.)

18,766. The general result has been that wherever total evacuation has been speedily accomplished in a growing epidemic the epidemic has decreased rapidly, and then has ceased in a short time?—Yes.

18,767. Have you largely made use of disinfection?—Yes.

18,768. And what views have you formed with regard to its value as a plague measure?—I have stated in my précis of evidence that I had no reason to suppose that it produced any good result; but I do not think I ought to have said that, because, as a matter of fact, disinfection has been carried out in almost every case I have had anything to do with. I can point to no instance in which disinfection clearly produced an effect upon plague, but as disinfection was always resorted to, I am not in a position to say what would happen if it were dispensed with. My objections were based largely on the ground that it was so badly done that it could not be of any value.

18,769. It was insufficient because it was done so badly?—Yes.

18,770. Can you describe how it was done?—The disinfection was almost entirely done with perchloride of mercury. We used syringes of different kinds, metal and wood. We washed the walls and floors of the houses with the perchloride of mercury as well as we could. That is the disinfection I saw myself. I have reason to believe that when there was no officer to supervise it it was not properly done, *i.e.*, the walls and floors were not thoroughly washed with the solution.

18,771. But I suppose you saw it sometimes properly done?—Yes.

18,772. What was the result in those cases?—I have never had an instance in which I could say it produced any result at all.

18,773. Did plague re-appear in properly disinfected houses?—In the next epidemic. I do not wish it to be assumed that I call the system of disinfection I used "proper" disinfection, all I mean is that my object was to thoroughly wash the inside of an infected house with the disinfectant, and when I was present I saw that it was thoroughly washed.

18,774. But plague did not reappear quickly, not until after a considerable interval?—As a rule, nobody was allowed to go into the houses for two or three months after they had been disinfected.

18,775. You disinfected the houses; did you do anything more to the houses before the people were allowed to enter them?—We took off a good many tiles, and opened the windows where we could.

18,776. Had you any recurrence of plague in the houses you treated in that way?—I know of no case of recrudescence except as part of a general recrudescence.

18,777. You had some experience of this matter, I believe, in Bassein town?—Yes.

18,778. What?—Bassein town is an exceptional case, because it appears that, in Bassein, there was a permanent source of infection, that is to say, it appears that there were two or three epidemics, and in each epidemic the first infection came from one particular place.

18,779. Had this particular place been disinfected?—Yes, it had been disinfected over and over again.

18,780. You bring that forward as an example of the inefficacy of disinfection?—Yes, I do.

18,781. Have you any opinions to offer with regard to segregation?—In dealing with villages I think it is unnecessary, except to the extent of putting the people who are sick and their immediate relatives in huts at some distance from the others.

Mr. W. C. Shepherd, I.C.S.
17 Feb. 1899.

18,782. Therefore you think that partial evacuation may succeed?—It may succeed where the infected block is separated from the rest of the village; but, as a rule, I have found that plague cases occur in all parts of the village almost directly after it has been first infected.

18,783. Does the case of the Bassein Koliwada which you refer to have any bearing upon this matter?—I referred to the Koliwada as being an infected locality.

18,784. What do you think is the maximum size of a town in which complete evacuation could be effectively carried out?—It depends entirely upon the locality. If you had a wide plain which you could take up without much expense, you could evacuate a whole town of almost any size. There is no absolute impossibility about it.

18,785. Practically, there is no limit?—Practically, I should say there is no limit except that of expense.

18,786. Taking the towns one finds in India, about what is the maximum sized town that could be evacuated?—In the Thana district it could be very difficult to evacuate a large town because the country does not admit of it, it is all cut up into small fields, there is much broken ground and wooded country.

18,787. What is the largest town?—You could evacuate a town of 10,000 or 11,000 inhabitants in most parts of the district.

18,788. Did you find much resistance offered by the people?—Not so far as evacuation is concerned. We used to have considerable resistance to segregation. It was very unpopular indeed. That is one reason upon which I base my objections to it.

18,789. (*Mr. Hewett.*) What is your reason for thinking that dissemination by contact with infected persons is so rare that it may almost be ignored?—If dissemination was chiefly by contact, considering the way the people live in the villages, we should get a certain class of people infected first. If it began among a certain caste, several members of that caste would be infected before others; but, as a matter of fact we do not find that to be the case.

18,790. Is it your experience that people living close together, and having dealings with one another, do not get infected?—No, they do get infected, but people who do not have dealings with one another also get infected in the same town.

18,791. Do you find that neighbouring houses get infected in the same town?—Sometimes yes, and sometimes no. It varies. I could not give any general rule.

18,792. You said that mortality among rats generally occurred before you got a local case of plague?—That is my belief.

18,793. But are you certain that it occurred before you had an imported case?—I am certain that in some cases mortality among rats occurred before an imported case was reported.

18,794. Can you exclude the possibility of there having been an imported case?—Our information is so inaccurate before an epidemic that it is impossible to exclude that.

18,795. Do you think that it is likely that rats get infected from an imported case and then move plague about in a local area?—That seems to be the probable way in which it is spread in most of these villages, because it comes up in all sorts of places instead of following a regular course.

18,796. (*Mr. Cumins.*) You spoke of recrudescence, and said that you do not know of any recrudescence except as part of a general recrudescence. Did any case come under your notice where, apparently, an old germ, after lying quiescent for some time, woke up into activity again? Is that what you mean by general recrudescence?—No; by general recrudescence I mean when plague had stopped in a village it did not begin again except in the course of a general recrudescence of plague all over that district.

18,797. When plague began again in a village was that due to a secondinfection or to an old germ?—As a rule it was possible to trace it to the second infection, except in the case of Bassein which I quoted.

18,798. When villages or towns became infected a second time did the plague seem to reappear in the same houses?—Sometimes it did actually in the same houses where it appeared at first. Sometimes it did not. I can think of one case where it did undoubtedly, and another case where it began in the same part of a town, though perhaps not exactly in the same houses.

18,799. In this case where it began in the same house, or in the same part of the house, could you trace any re-infection from outside? Could you be certain that there was no re-infection?—No, I could not possibly be certain.

(Witness withdrew.)

Mr. E. L. Marsh.

Mr. Ernest L. Marsh called and examined.

18,800. (*The President.*) I believe you have been engaged in bacteriological work?—Yes.

18,801. (*Dr. Ruffer.*) I think you have been making some investigations as to the approximate numbers and varieties of micro-organisms recovered from samples of soil and dust from native dwellings?—Yes.

18,802. How did you take the samples of the soil in rooms?—I took samples from the surface of the earthen floor.

18,803. How deep?—The immediate surface, *i.e.*, scrapings from the surface. I collected the samples in sterile tubes, and carried the tubes immediately to the laboratory. Then one hundredth of gramme of the sample was inoculated into melted agar.

18,804. How did you weigh it?—I did not weigh the quantity actually examined. I first weighed a control quantity, and from its bulk I estimated the amount to use for the purpose of bacteriological examination. This amount was removed on the end of a sterile platinum rod furnished with a scoop of known capacity. I found that the method of estimation was sufficiently accurate. The estimated one-hundredth gramme was immediately added to a test tube containing 10 c.c. of melted agar. By shaking it it was distributed as evenly as possible through the agar, which was then spread over the surface of a Petri plate to solidify. The plates were incubated at the temperature of the room for 24–48 hours, when the number of colonies which had developed in the agar in the plate, and in the agar remaining in the emptied test tube were counted. Agar was employed because of its suitability as a solid nutrient material at the comparatively high temperature of the laboratory (80°–86° F.). For this reason alone the number of colonies counted is probably much lower than might have been obtained with gelatine had it been practicable to use that medium.

18,805. Can you give us the general results of your investigations in unoccupied and occupied rooms?—The houses examined were not necessarily plague infected houses; some of them were. I took samples from two unoccupied houses. One of these houses was in the servants' quarters in a bungalow on Malabar Hill, the other was in a plague district in Bombay. The highest number of colonies in one sample was 5 million odd (calculated for 1 gramme of the sample); the lowest number in a sample from these two houses was 8 thousand odd, while the average of 22 cultures from 22 samples was one million odd. These results were obtained for unoccupied houses. From occupied houses the highest number from any one sample was 8 million odd, and the lowest number from any one sample was 126 thousand odd. The average was 3 million odd.

18,806. So that there is a rather larger number of micro-organisms in the occupied houses than in the unoccupied houses?—Yes.

18,807. Were they the same kind of floors?—Yes.

18,808. In the same quarter of the town?—One of the unoccupied houses was in the servants' quarters in a bungalow on Malabar Hill. The other house was in a plague district.

18,809. What did you find in the disinfected and unroofed houses?—In the two disinfected houses examined the highest number of colonies in any one

sample was 4 million odd. Two samples were sterile. The average of 25 cultures from 25 samples was 1 million odd.

18,810. So that it was very much lower than in the occupied houses?—Yes.

18,811. How had the houses been disinfected?—With perchloride of mercury.

18,812. Did you take any steps to neutralize the perchloride when you made your agar plates?—No.

18,813. There might have been some perchloride of mercury sticking to the sample?—There might have been. I thought I would give the sample all the advantage of the fact that it had been treated by perchloride of mercury.

18,814. How long after disinfection were your examinations made?—The samples were collected and the examinations made from within a few hours to four days after disinfection.

18,815. What did you find in unroofed houses?—I examined one, and the highest number of colonies in one sample was 1 million odd, and the lowest number was 2,000. The average was 500,000.

18,816. What conclusion do you draw from that?—That the average number of colonies of micro-organisms in 25 cultures from 25 samples from disinfected houses was 25 per cent. less than the average number of colonies in 22 cultures from 22 samples from unoccupied houses, and 65 per cent. less than the average of 20 cultures from 20 samples from occupied houses.

18,817. What was the nature of the microbes you found?—They were in great variety. The spore-bearing organisms were the commonest.

18,818. In all the samples could you give us the exact result of what you found?—The majority of bacteria recovered from the various samples were obligate saprophytes, dealing with oxidation, nitrification, and formation of carbonic acid of the dead and decaying matter in the filth of the houses. A large number of the samples contained species of the more sensitive facultative parasites. Divided into spore-bearing and non-spore-bearing forms the following account may be given:—Spore-bearing: B. subtilis, B. mycoides, B. vulgatus, B. mesentericus, B. butyricus; Non-spore bearing: B. coli communis, and other species of the coli group; Bac. vulgare, and other species of proteus; Bac. acidi lactici, Bac. fluorescens, Bac. syncyaneum, Bac. prodigiosum, Bac. janthinum, Bac. pyocyaneum, Micro. candidans, Micro. agilis, Micro. luteus, Micro. pyogenes aureus, citreus, and albus, streptococcus pyogenes, staphylococci, sarcinæ, moulds, yeasts. The spore-bearing species were ubiquitous, and in a great preponderance.

18,819. Did you find any difference between the number of the spore-bearing and other organisms in disinfected houses?—I cannot give you exact figures.

18,820. What is your impression?—My impression is that I found a greater number of spore-bearing organisms in disinfected houses.

18,821. That is simply an impression; you have no actual numbers?—It is a very strong impression.

18,822. So that perchloride of mercury and whitewash would kill off most of the non-spore-bearing organisms and leave the spore-bearing organisms?—Yes.

18,823. Are the spore-bearing organisms mostly non-pathogenic?—Yes.

18,824. It would not matter very much whether they were left alive?—No; my method of culture, however, only allowed me to recover the aerobic micro-organisms; it only deals with the aerobic micro-organisms.

18,825. How did you collect the dust on the floors or walls?—The samples from the floors included dust, cow dung, and dirt.

18,826. What result did you get from the dust on the walls of unoccupied and occupied houses?—The results are included in the statement I have given.

18,827. You mixed the two together, the soil and dust?—Yes. I took 14 samples, as a rule, from each house. The majority of the samples were from the floor, but three or four samples would be taken from the walls.

18,828. I believe you have made experiments with bubonic microbes and cow dung; could you give us the particulars of your experiments?—In carrying out this series of experiments the object was to reply to a letter received by M. Haffkine from Mr. Cumine, in August, with regard to the action of perchloride of mercury on cow dung and cow dung floors. In conducting the series of investigations, I tested the samples of perchloride of mercury against sterile cow dung to discover what effect sterile cow dung had in neutralizing a solution of perchloride of mercury. In the experiments of Mr. Hankin and Dr. Pitchford, perchloride of mercury dissolved in sterile water in the proportion of 1 in 5,000 caused the death of a pure culture of the plague micro-organism after one minute's contact. I found that by adding to 10 c.c. of perchloride of this strength a quantity of cow dung equal to 2 grammes or more, the disinfectant no longer existed; it was neutralized.

18,829. Will you give us the details of your experiments upon that point?—A series of test-tubes containing from ·5 gramme to 5 grammes of sterilized fresh cow dung in the form of dust was prepared. A measured quantity of sterile distilled water containing perchloride of mercury in solution was added to the tubes, so that each tube held the test amount of cow dung mixed with 10 c.c. of water containing ·002 gramme of perchloride of mercury, or a proportion of 1 in 5,000. At the same time each tube received a glass bristle wetted in its lower third by a thin film of living culture obtained from the surface of a three days old agar growth of plague. The experimental tubes were kept at the temperature of the laboratory for 18 hours. At the end of this interval the glass bristles infected with plague were withdrawn from the paste of cow-dung and perchloride solution in the different tubes, washed in a weak solution of carbonate of soda, and inoculated *seriatim* into tubes containing 20 c.c. of nutrient broth. The culture tubes were incubated at the temperature of the laboratory for ten days, and their ability to produce fresh culture of the test organism was as follows:—

Gramme of Perchloride of Mercury in 10 c.c. of Distilled Water.	Amount of sterilized Cow Dung acted upon.	Growth in Broth after 18 Hours attempted Disinfection.

,,	4·5 ,,	+
,,	5· ,,	+

I found that tubes containing quantities of cow dung of 2 grammes and less were disinfected, but those containing quantities of cow dung above 2 grammes were not disinfected of the test organism.

18,830. That was a neutral solution of perchloride of mercury?—Yes, an aqueous neutral solution.

18,831. Did you make any experiments with an acidified solution?—Yes.

18,832. Could you give us the particulars?—I have not done an experiment in which the results might be compared with the results just stated, but in my next experiment I used a solution of the formula and the strength commonly used in Bombay, viz., one in 725, 1015, and 152 of perchloride of mercury, chloride of ammonia, and hydrochloric acid respectively.

18,833. You made it up yourself?—I made a control sample myself, and I got a sample from one of the disinfection officers in Bombay and compared them one with the other.

18,834. What were the results?—They are detailed in the following experiment. Two series of test tubes containing from ·2 gramme to ·3 gramme of cow dung (weighed dry) were prepared. A measured quantity of the test solution was poured into the tubes so that each tube held the test amount of cow dung wetted with 10 c.c. of the disinfectant solution. Care was taken to thoroughly wet the cow dung with the solution, 10 c.c. of which should moisten dry cow dung in a fine state of division up to five grammes. At the end of 18 hours a minute quantity of the cow dung was

Mr. E. L. Marsh.

* Spores of moulds and of bacillus megatherium, B. subtilis, and B. mycoides obtained from the unsterilized cow dung. Whenever equivocal results seemed to be obtained the tests were repeated.

This experiment also shows the comparative results obtained with a laboratory prepared solution and a sample of the solution obtained from disinfection officers in Bombay.

18,835. Kindly give us that?—It is expressed in the statement that ·5 gramme of ordinary cow dung can be efficiently sterilized by 10 c.c. of the laboratory solution, but not by the other solution. The sample from the plague officers showed a very slight difference however.

18,836. What was the difference? — A difference measured by the fact that the laboratory solution sterilized ·5 gramme. The plague officers' solution did not sterilize that but sterilized ·4 gramme.

18,837. A difference of 20 per cent.?—Yes.

18,838. What other experiments have you made?—The experiment which has just been mentioned was repeated in all its details with living cultures of the plague bacillus as the test organisms. Each tube received in addition to the cow dung and disinfectant solution a glass bristle infected with a culture of the plague microbe recovered from a broth culture 15 days old. Care was taken to wash the bristles in sterile water to remove the adherent broth before inoculating them into the test tubes. On withdrawing the bristles at the end of the experiment they were first washed in sterile water made faintly alkaline with carbonate of soda, then agitated in melted agar, and finally plated from a second tube of melted agar for observation and recovery of the test organisms. Although this method of differentiating and identifying the test organism is not a delicate one, still, in the absence of animal inoculation tests, it appeared the most satisfactory one to employ. The use of broth is very unsatisfactory, owing to the rapid vegetation of the common saprophytic micro-organisms. In those instances where the results seemed to fall short of accurate demonstration the tests were repeated. The results obtained were as follows:—

Gramme of Perchloride of Mercury in Solution with Chloride of Ammmonia and Hydrochloric Acid in 10 c.c. Water.	Amount of unsterilized Cow Dung acted upon.	Growth of the Plague Bacillus after 18 Hours attempted Disinfection.	
		Control Solution.	Bombay Solution.

The results show a small success of the control solution over the Bombay solution, the latter being capable of a germicidal action on 1·5 grammes of cow dung experimentally infected with the organism of plague, the former a similar action on 2 grammes.

18,839. You refer to the action on the plague bacillus?—Yes, as the test organism in this experiment. The results were attained by 10 c.c. of a solution of 1 in 725 strength, an acidified solution.

18,840. In that case the sublimate would have to go through a considerable layer of cow dung before it got to plague bacillus? That is not quite the condition of nature, is it? There would be a layer of, say, a quarter of an inch of cow dung between the plague bacillus and the sublimate?—Not so much as that. The glass bristle was inserted into the mass of cow dung, and the cow dung was thoroughly moistened with the disinfectant. It is just as likely that the disinfection was in contact with the glass bristle as with any of the cow dung particles.

18,841. Do you moisten the cow dung before you put the bristle in?—No. I put the bristle into the cow dung first, so that the results may not be varied by the action of the cow dung in neutralizing part of the disinfectant. Then immediately afterwards it was moistened with the disinfectant.

18,842. It was simply moistened? — It was made wet. 10 c.c. very thoroughly moisten quantities up to 2 grammes of cow dung. In fact, 10 c.c. will moisten 5 grammes.

18,843. Have you any other experiments on that point?—I took samples scraped from the surface of native floors and used them as the test material.

18,844. In plague houses?—Yes, houses which had been notified to me by a plague officer.

18,845. Do you put in all those experiments?—Yes. In these experiments the Bombay solution was further tested. Instead of ordinary cow dung the test material employed was dried mud and cow dung dust scraped from the floors of native dwellings. The results obtained are detailed in the following experiment on the germicidal value of a sample of perchloride of mercury used in Bombay for disinfecting native houses:—

* Spores or moulds and of B. megatherium, subtilis, and mycoides, were commonly obtained from the unsterilized material.

From the results it would appear that an amount of earth and cow dung from the floor of a native dwelling over ·3 gramme is not efficiently sterilized by 10 c.c. of a solution containing perchloride of mercury in the proportion of 1 in 725.

18,846. Is it sterilized as far as non-sporing organisms are concerned?—I failed to recover any non-sporing organisms in less than ·7 gramme of the test material.

18,847. Have you ever tried the following experiment, to put plague microbes in cow dung floor, pour the solution on it, and see then whether the plague is not destroyed? — I have not done an experiment actually in that way, but I have done one with pieces of a cow dung floor kept as samples in the laboratory.

18,848. Will you give us that experiment?—I took a 4-inch square of dry cow dung floor, and inoculated the surface with plague micro-organisms contained in a watery emulsion made from an agar culture. Then I poured on the surface of the piece of floor 10 c.c. of the 1 in 725 solution, and after 20 minutes took a scraping from the treated surface, which I inoculated into agar for plate cultivation of the plague bacillus, but failed to recover the organism. I also inoculated an animal with negative results.

18,849. In all these cases I do not quite see how you neutralized the perchloride of mercury; was it simply by a carbonate of soda solution?—Yes.

18,850. By a weak alkali?—Yes.

18,851. By that weak alkali you would neutralize the acid, but you would not neutralize the mercury, would you?—Yes.

18,852. My difficulty is, that perhaps your results are too good. I should have thought that if you put a certain amount of mercury with a plague microbe into a tube, unless you took some special measures to neutralize the disinfecting action of the perchloride of mercury, you would have a sort of film of perchloride of mercury round your microbe, which might prevent it growing?—I tried by means of a weak alkaline solution of carbonate of soda to neutralize the mercury.

18,853. Have you any experiments bearing on that?—No personal experiments.

18,854. My objection is probably quite fallacious; I only suggest it?—I think that experiments have been done, because when perchloride of mercury is used in very strong solution as a disinfectant it is the practice of the disinfectors in certain places to follow up the use of the mercury salt with a solution of carbonate of soda with which to neutralize it.

18,855. What other experiments have you got?—The last experiment was repeated with living cultures of the plague organism, the test material being scrapings of the floors of native houses. The results showed that ·8 gramme of earth and cow dung from the floor of a native dwelling is not efficiently sterilized by an acid solution of perchloride of mercury of the strength of 1 in 725.

18,856. As far as the plague microbe is concerned?—Yes.

18,857. How did you do it in the experiment with the dust; did you ram the dust down to the bottom of your tube? How did you mix the plague microbe with the dust?—I still used the glass-bristle method.

18,858. Was the dust loose or firmly bound together?—It was loose cow dung dust; it was ground down in the form of a powder.

18,859. Have you any other experiments?—I took the reaction of the disinfectant solution after contact with several quantities of cow dung and earth floor, and found that, while a control sample of the disinfectant solution always gave a strongly acid reaction, within two minutes' contact with 2 grammes cow dung and earth the reaction was affected to such an extent that it was only acid, no more than acid, with ·5 gramme the reaction was neutral, and with ·9 gramme the reaction was alkaline.

18,860. You want to add a considerable amount of acid to your solution?—Yes. From half to three-quarter per cent.

18,861. Have you any further experiments on cow dung?—No.

18,862. What conclusion do you draw from your experiments?—I concluded that 10 c.c. of an acid solution of the strength of 1 in 725 (Bombay formula) efficiently disinfects 1·5 grammes of cow dung experimentally infected with the organism of plague, but does not suppress the more resistant saprophytic bacteria. I also concluded that 10 c.c. of the 1 in 725 acid solution efficiently sterilizes ·7 gramme of cow dung floor experimentally infected with the organism of plague. It also reduces the number, but does not suppress the more resistant saprophytic bacteria. Also that as the effective limit of the 1 in 725 acid solution, in regard to disinfection against plague, is represented by the action of 10 c.c. of the solution on ·7 gramme of cow dung floor, and as ·7 gramme of cow dung floor is the amount commonly recoverable from 4 square inches of the earthen floor of a native house when the immediate surface for a depth of $\frac{1}{16}$ of an inch is removed, then 100 square feet (14,400 square inches) would yield 2,520 grammes, which amount of surface material would require approximately 8 gallons (three bucketfuls, the buckets being of a capacity of $2\frac{3}{4}$ gallons—many of the wooden buckets in Bombay have a capacity of only $2\frac{1}{2}$ gallons) of the 1 in 725 acid solution to vitally damage any contaminating plague micro-organism. But if the infectious material were below the immediate surface under disinfection, or on the surface protected by leaves, bits of rag, &c., then with such an application it could hardly be hurt at all. In a test observation in which 8 samples of dirt and cow dung from a room were examined before disinfection, and 12 samples from the same room immediately after disinfection, and in which care was taken that the quality and amount of perchloride of mercury used and its method of application allowed a 1 in 725 acid solution to produce its maximum effect, a comparison of result showed that while 4,057,800 was the average number of colonies of micro-organisms recovered from 1 gramme of each sample before disinfection, the average number after was 228,300—a reduction of about 94 per cent.

18,863. That is counting both sporing and non-sporing organisms?—Yes.

18,864. Then you have some experiments on the microbes of bubonic plague in relation to earth?—Yes.

18,865. What are your experiments with regard to the microbe of bubonic plague and sterilized garden mould?—That in sterilized mould it can have a continued existence up to 13 days.

18,866. How did you perform that experiment?—I took quantities of garden mould and sterilized it in test tubes in an autoclave, and made sure that it was sterile by control experiments. Then I inoculated the sterile earth with a culture of plague micro-organisms taken from the surface of an agar tube, and I also introduced a glass bristle infected in the same way as I have already described in the former experiments. At the end of intervals of from 1 to 13 days or more a glass bristle was removed from the sterile earth and inoculated into a culture tube of broth, and also a quantity of the earth itself was removed at the end of a platinum loop and inoculated into another series of broth tubes, and the results obtained culturally.

18,867. Did you make any experiments in unsterilized garden mould?—Yes. I got the plague micro-organisms to live in unsterilized garden mould from 4 to 6 days.

18,868. Do you think your experiment is quite a fair one? Supposing you put the plague bacillus sticking to the bristle, it is not in the same condition as if it were mixed with garden earth, is it?—With sterile media it really did not matter. I got the plague micro-organism from particles of the sterile media. With unsterilized media it was very difficult to recover the organism unless I adopted that method along with other methods. While the glass bristle method yielded these results, the results when I took a particle of non-sterile medium were very unsatisfactory. Owing to the difficulties that had to be overcome in the bacteriological proof of a few plague germs where there were crowds of saprophytic organisms, I could not be sure of them.

18,869. Were you able to isolate the plague bacillus again when you mixed it with unsterilized garden mould?—Only up to the length of time mentioned.

18,870. When you mixed it thoroughly with the garden mould, not with a glass bristle, but in a dish or tube, and powdered it all up together, could you then isolate the plague bacillus again?—I have done so up to short intervals.

18,871. It is a very difficult thing to do, is it not?—Yes.

18,872. Is it a matter of weeks?—Yes; it is very difficult.

18,873. Then it is very doubtful that you would get it in all cases, is it not?—I never used that method, because of its difficulty, when I wished to test if the organisms were alive for longer periods than 24 hours.

18,874. Have you given us all your experiments on earth and cow dung?—No. I have made laboratory experiments on sterile earth, sterile tap water, and sterile cow dung. I found when the plague microbes were inoculated into these materials that the conditions were favourable to their continued existence up to 13 days, 44 days, and several months respectively.

18,875. How much culture did you add to the sterilized tap water?—I did it in the way already described, with a glass bristle—the amount that would adhere as a delicate film to about one-third of the length of a glass bristle about 3 inches long.

18,876. Bombay tap water?—Yes, sterilized.

18,877. (*Prof. Wright.*) How long did the plague bacillus live in cow dung?—It lived several months in sterile cow dung.

Mr. E. L. Marsh.

17 Feb. 1899.

18,878. Is that moist cow dung?—Yes.

18,879. Wetted with Bombay water? —Yes, and sterilized.

18,880. (*Dr. Ruffer.*) How long did it live in non-sterilized cow dung?—Never after six days.

18,881. How about sterilized tap water?—The period was 44 days.

18,882. And in ordinary tap water?—Never after six days.

18,883. When you recovered it from water how did you make sure it was plague bacillus in the ordinary water?—I did animal control experiments.

18,884. (*Prof. Wright.*) Was the plague bacillus virulent after that time?—Yes. It was not virulent in the sense that it always killed the animal, but of a series of animals some sickened, and some of the sick died of plague.

18,885. (*Dr. Ruffer.*) Have you any other experiments on water?—No.

18,886. Have you any experiments with the microbe of bubonic plague in relation to dessication in sterilized air and ordinary air?—I did some experiments simply to find out how long the plague micro-organisms would live on glass bristles in ordinary air and in sterile air. I found in exceptional cases they lived as long as 48 hours on the glass rods. I inferred that that was due to the fact that there was probably a thicker film on the glass rod than usual.

18,887. Did you try sterilized articles of clothing inoculated with the plague microbe?—Yes.

18,888. How long does it live in them?—Never longer than 18 hours.

18,889. How did you expose your sterile clothing: did you put it away in the dark or hang it in a room?—I exposed it in a sterile chamber.

18,890. Did you dry it or keep it moist?—I kept it dry.

18,891. Then the desiccation may have acted?—Yes.

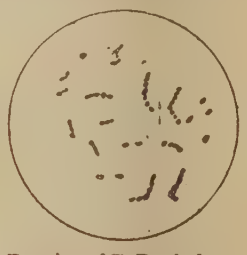
18,892. Have you made any experiments such as contaminating a shirt or a vest with the plague, and then rolling it up in the usual way in which you would send it to the wash, and then put them away in a drawer?—No, I have not.

18,893. Have you any facts with regard to the growth of the plague micro-organism in ground air, and in artificial admixture of certain gases and ordinary air?—Yes. A series of six ordinary test tubes containing a four days' agar growth of plague (obtained from broth culture three days old, from a previous broth culture 10 days old, from an agar culture direct from bubo in a case of plague) were buried 9 to 12 inches below the surface of the soil in Bombay on January 3rd 1899.* The place of burial for two of the tubes was the earth of the floor of a native house, the remaining four tubes being buried in garden mould in the open. Control tubes containing cultures of the same age and pedigree as the above were kept in a dark cupboard in the laboratory. The tubes buried in the garden mould were allowed to remain undisturbed for 9, 23, and 28 days respectively. Of two tubes removed at the end of nine days one was discovered to be invaded by mould-fungi. The other tube was pure. This tube presented a slightly exaggerated growth of plague when contrasted with the control tubes kept in the cupboard. In the tubes removed after 23 and 28 days burial the growths were notably exaggerated. The appearance of the culture viewed by obliquely transmitted light was not the simple ground glass appearance of the control tubes, but that of a thick opaque growth. At a number of points the growth had developed what looked like secondary colonies, of a dull waxy appearance. These colonies had regular margins, and stood out well from the original arrangement of the growth. Stained specimens from the last two tubes showed under the microscope (× 800) bacteria of consistent shape and much larger dimensions than the average. The bipolar arrangement of the protoplasm was defined with unusual distinctness for an agar culture. A still more noteworthy feature was the presence of chain formations. As many as 20 to 30 individual bacteria were commonly counted in the chain fragments visible in the field. The chains were not exactly comparable to the short streptococcus-like growths obtained from a bouillon culture of plague made alkaline with carbonate of soda. They were stouter, and showed the bipolar markings of the individual bacteria in a prominent manner. A number of the chains presented an appearance of striation due to the presence of vacuoles. In the two growths buried in the floor of a native house for 23 days similar cultural and microscopical appearances were obtained. The occurrence of vacuolation in the elements of the chains was perhaps less marked.

Inoculated into broth, typical and vigorous growths occurred in each instance.

One drop of a broth sub-culture (24 hours old), from one of the agar cultures buried in the soil of a native floor, injected subcutaneously into a white mouse caused death within 18 hours. A similar dose of a broth sub-culture from a control tube was fatal after 50 hours.

Drawing of B. Pestis from an agar culture buried 23 days, 9 inches below surface of soil.



Drawing of B. Pestis from from a four days' broth culture made alkaline with carbonate of soda.

The above series of facts would seem to indicate that soil-air is possessed of conditions that are at least favourable to the growth and multiplication of the plague micro-organism. As the results obtained suggest that the dilution of the oxygen in ground air by carbonic acid is advantageous to the vegetation of the organism, a series of experiments was done in order to reproduce roughly similar conditions in the laboratory. The amount of carbonic acid in ground air being on an average from 2 to 3 per cent., or about 1 per cent. less than the amount in air expired from the lungs, an admixture of air and carbonic acid in the proportion of 3 per cent. carbonic acid was used in an initial experiment on agar test-tube growths of plague (one day old). The test tubes (four in number) were allowed to remain in this atmosphere in the dark at the ordinary temperature of the laboratory (82–88° F.) for two to six days. As a result of this treatment the growths were found to be much more luxuriant than growths obtained in control tubes kept under the ordinary atmospheric conditions in a cupboard. Under the microscope the individual bacteria were large and showed a clear outline with prominent bipolar arrangement of their protoplasm. The chain formation characteristic of the underground growths was evidenced by short chains of several bacteria. Owing to the occurrence of vacuolation in many of the chains, the appearance of striation sometimes so well seen in the diphtheria bacillus was observable.

In the next experiment the fact of there being (probably) a larger amount of carbonic acid than 3 per cent. in the air in the superficial soil of native houses was considered. The abundance of organic matter, the comparatively high ground temperature, the presence of moisture, and absence of ventilation, would probably make the per-centage of carbonic acid present approach the maximum limit of carbonic acid found in ground air, namely, 14 per cent. Three test-tube growths of plague on agar, one day old, were accordingly exposed to an admixture of moist air and carbonic acid con-

* Readings of a Thermometer the Bulb of which was 9 inches below the Surface of the Ground. Government Observatory, Bombay.

12	76·6				

taining the latter in the proportion of about 14 per cent. The growths exposed to this condition of atmosphere at a temperature of 92° F. for three to nine days were found to thrive particularly well.

In an experiment in which a cent. per cent. admixture of air and carbonic acid was used at the laboratory temperature the growths appeared to do no better than in ordinary air. In an atmosphere of almost pure carbonic acid the cultures appeared to be inhibited in their growth, but otherwise not seriously interfered with. Stained specimens examined microscopically showed a number of involution forms.

From the above, it would appear that an admixture of 14 per cent. of carbonic acid and 86 per cent. of ordinary air at 92° F. favours and enhances the growth and reproduction of the plague micro-organism.

As has been already mentioned, the advantage of the presence of carbonic acid seems to exist in the fact that it acts as a diluent of the oxygen, and not for any special favouring influence it might have on the plague bacillus. When nitrogen was used instead of carbonic acid, so that 100 volumes of air, instead of containing 79 volumes of nitrogen, were made to contain 85 volumes, a very similar increase of development was noticeable. In this case, however, the microscope did not show the excellent specimens obtained with carbonic acid. Air containing a proportion of nitrogen equal to 90 per cent. did not appear to help the vegetation of the micro-organism.

With hydrogen gas in 25 and 50 per cent. admixture with air the growths did not appear to be specially benefitted. Under the microscope large numbers of involution forms were obtained from an agar culture (two days old) that had been subjected for four days to an atmosphere containing 50 per cent. hydrogen. In a series of agar test-tube growths of plague (two days old) the cultures were found to produce involution forms in abundance and rapidity as the amount of hydrogen was increased. When hydrogen gas was made to pass through nutrient broth containing a four days' growth of the plague bacillus the growth was not sterilized, but large and exaggerated involution forms were obtained in 24 hours with an abundance and similarity of shape to those obtained from a culture of the plague bacillus in sterile tap water at the end of 44 days' growth at ordinary temperature.

Mr. E. L. Marsh.
17 Feb. 1899.

This circumstance would indicate that the conservation of the plague micro-organisms in a living condition is favoured by the production of involution forms.

The shapes of the involution forms appeared to be correlated with the nature—whether solid or liquid—of the medium in which they happened to be present. On solid media the tolerably fixed dimensions and shape of the normal bacilli were confused among the involution forms. They had no certain standard of size, or consistent shape: the usual shapes had a bulbous and a tenuous end, with the protoplasm massed on one side. In broth and sterile water the involution forms appeared to be able to retain the shape commonly characteristic of the normal organism. They were usually spherical or swollen-up masses of protoplasm several times the size of the normal form. It was possible to cultivate the involution forms obtained from the agar hydrogen-treated tubes during three generations of sub-cultures.

Drawing of B. Pestis (showing involution forms) from an agar H-treated culture.

Drawing of B. Pestis (involution forms) from a broth hydrogen gas treated culture.

Drawing of B. Pestis (showing involution forms) from a sterile tap water culture 44 days old.

The use of an atmosphere diluted as regards its oxygen by the use of 10 to 15 per cent. of carbonic acid was found to be specially serviceable in occasioning the vegetation on agar of plague micro-organisms existing in small numbers in the blood or tissues of animals dead of plague. It was found that when the infected blood or tissue pulp were inoculated on to agar vigorous growths of the plague micro-organisms were invariably obtained within 24 hours when carbonic acid was used, whereas tubes not so treated, but exposed to the ordinary air in an incubator, either did not develop the characteristic agar growths of plague at all, or did so very slowly.

It was also found that the dilution of the oxygen by the use of 10 to 15 per cent. carbonic acid was helpful in retaining the virulence of cultures of the plague micro-organisms growing in artificial media. Cultures which had made several passages through rats, and experienced growth on artificial nutrient media, such as agar and broth, in the intervals of their existence outside the bodies of the experimental animals, were occasionally found to have lost their virulence, whereas similar cultures placed in an atmosphere containing a diminished amount of oxygen did not lose in virulence.

18,894. Have you any other experiments you wish to put before us?—No. I have made other experiments, but the results are still under investigation.

18,895. You have some clinical memoranda of two cases admitted to hospital at Poona with bubonic plague eight and nine months respectively after inoculation with Dr. Haffkine's prophylactic?—Yes.

18,896. What is the general result of your observations in the first case, the one admitted on the 5th January 1898?—There is nothing special about it except that the man had been in frequent contact with plague for several months. In fact both cases had been in close association with plague and plague-infected spots for some considerable time before becoming infected. I wished to draw attention to their succumbing to the infection only late after inoculation.

18,897. Eight and nine months after inoculation?—Yes. They were ordinary cases of bubonic plague, there was nothing special about them. They both recovered.

18,898. There is nothing more you wish to especially call attention to?—No.

18,899. Do you think they ran a milder course?—Perhaps one of them did, but there were many equally mild cases of plague among uninoculated cases.

18,900. Who inoculated them?—I could get no precise information about that, except that one of the district officers in Bombay had inoculated them.

18,901. How did you know they were inoculated?—I saw their certificates of inoculation.

18,902. Had they been inoculated once or twice?—One twice and the other once.

18,903. Do you know whether either of them reacted to the inoculation?—Yes, one was ill for two days and the other felt ill for 24 hours after the two occasions on which he was inoculated.

18,904. You have had some clinical experience of plague?—Yes.

18,905. Do you ever find high rises and falls in the temperature of plague?—Yes, regularly on the fourth or fifth day; any pyrexia later on in the illness was usually due to the fever of suppuration.

18,906. You have also some records of bacteriological examination for diagnostic purposes of the circulating blood or material from a painful gland in 25 of the patients admitted to the observation wards of the Poona Plague Hospital?—Yes. Of 1,593 cases admitted for observation to the Poona Plague Hospital, 650, or 41 per cent., were diagnosed as cases of plague without much difficulty. The 25 cases under remark were

Mr. E. L. Marsh.
17 Feb. 1899.

doubtful cases. Where these was no doubt the case was either sent into the hospital as plague or kept in the observation camp till better of the condition that simulated plague. Of the 25 doubtful cases examined bacteriologically four were in the second day of illness, 15 in the third day of illness, 3 in the fourth day, 2 in the fifth, and one in the sixth day.

18,907. Had they any other symptoms besides?—Yes. Some of them had symptoms of malarial fever, and that helped to make them doubtful. Examination of the circulating blood in the 25 cases by smear inoculations on agar culture media gave positive results in only three cases (all fatal), a proportion equal to 12 per cent. The examination of glandular material in 18 of the cases ——

18,908. What do you mean by glandular material; did you put a needle into the gland?—I put a needle in some cases, in others a very thin glass pipette, into the gland, and got some lymph and blood from the gland. An examination of this material in 18 cases presenting some glandular symptoms or condition such as hardness, tenderness, or slight enlargement, gave positive results in 14 cases, a proportion equal to 79 per cent. Thus the 25 cases yielded positive results to bacteriological examination in 17 cases, a proportion equal to 68 per cent.

18,909. Did the clinical symptoms afterwards bear out your bacteriological diagnosis?—There were only one or two cases in which doubt continued to exist.

18,910. As a rule have you got typical plague afterwards?—As a rule they were found to have plague.

18,911. You got other symptoms showing they had plague?—Yes; these examinations were made a few hours after admission, and the clinical evidence later on showed they had plague.

18,912. Even the cases in which the bacteriological examination gave a negative result turned out to be plague?—I found that several (two or three) of them turned out to be plague.

18,913. Have you any facts with regard to the presence of plague bacilli in the blood of patients who ultimately recovered?—I enclose two clinical charts* giving short record and character of fever in two cases of plague septicæmia, in which the organism was cultivated from the blood on the fifth and sixth days of the disease respectively. The patients recovered. Of 18 cases of plague septicæmia in which the organism was recovered from the blood, only two (the present cases) ultimately recovered.

18,914. (*Mr. Cumine.*) Have you any reason to believe that the floor of which you took scrapings had already infected some human being with plague?—I cannot say definitely that it had. It was, however, in a plague-infected house.

18,915. (*The President.*) Did you examine any food substances?—No.

18,916. Did you examine milk?—No.

* *See* Appendix No. LVI. (i.) and (ii.) in this Volume.

(Witness withdrew.)

Mr. E. F. Allum.

Mr. E. F. Allum, called and examined.

18,917. (*The President*). What is your occupation?—I am a merchant of Bombay. I have been doing plague work in Bandra.

18,918. (*Mr. Hewett.*) You are a member of the Bandra Municipality and Chairman of the Sanitary Committee?—Yes.

18,919. Were you employed in the first plague epidemic in Bandra?—No, I commenced in December 1897, and have continued since.

18,920. How did the place get infected the second time?—It broke out in the village of Khari at the end of December 1897. There were two cases imported from Santa Cruz, which is about two miles from Khari, on the north side.

18,921. Did it get into Bandra from the village of Khari?—Khari was the first village attacked in the whole district of Bandra. There are about half a dozen villages—in addition to the town of Bandra—in the district.

18,922. How did the town of Bandra itself become infected?—The first case in Bandra was in February; I think that was a compositor in Bombay who was living in Bandra. A large portion of the population of Bandra go to Bombay for their occupation.

18,923. During this time there was no interference with their moving between Bombay and Bandra?—No.

18,924. How many cases occurred in the second epidemic at Bandra?—The number of cases for the whole year was 358 attacks and 322 deaths. That is from December 1897 to November 1898.

18,925. Were the majority of these cases in Bandra itself or in the villages?—The majority were in Bandra itself, and occurred mostly in July and August.

18,926. You have never been able to stamp plague out entirely in the town of Bandra?—In November we came down to two cases for the month; in December there was a recrudescence, and this year it is worse than ever.

18,927. Is it bad at present?—In this last December there were 17 attacks and 12 deaths. For the previous December there were only 2 deaths. In January this year there were 56 deaths from plague, and in January last year only 9 deaths. From the 1st to the 15th February this year there were 34 deaths from plague; in February last year there were only 17 deaths for the whole month.

18,928. During the second epidemic in Bandra itself, did you take the people to hospital and isolate the contacts?—In Bandra we had a case in February, and there were isolated or sporadic cases till July; then there was an epidemic at the south end of the town.

18,929. Did you turn the people out of any portion of the town?—When the epidemic came to Bandra it was worst in July and August and that was in the middle of the rains so we could do nothing. In addition to that, it was principally in the Muhammadan quarter of the city, and one could do little with these people. We got some of the Hindus to go out, but we could do little with the Muhammadans.

18,930. Is that still the case?—There is the greatest difficulty in getting the Bandra people out of their houses.

18,931. Is there a difficulty in ascertaining cases in Bandra?—Yes, there is a great deal of concealment.

18,932. How do you endeavour to ascertain the cases?—We have inspectors going round, we have no house-to-house visitation, simply Sanitary Inspectors going around.

18,933. Did you find most cases while the patient was still alive or after death?—We generally get intimation just before the patient is dying.

18,934. In such cases, do you find that some of the contacts have disappeared, or are they generally all present?—Sometimes they are there, and sometimes they are not. It is difficult to trace them in a large place like Bandra, it is easier to trace the people in the villages.

18,935. I believe you treated some of the infected villages in the neighbourhood of Bandra in one way and some in another, please specify the different methods of treatment and the results?—In Khari, in the outbreak of the epidemic, all the people were moved out from the village into huts outside, and we insisted upon all patients being removed to hospital immediately on detection.

18,936. What is the population of Khari?—Roughly speaking from 800 to 1,000. About 12 cases had occurred before the people camped out. All cases immediately on detection were removed to the hospital. Some member of the family was allowed to go with the patient, and the rest were isolated in our segregation camp for six or seven days.

18,937. How long did it take to stop the plague in this village?—It died out about the end of February—about two months.

18,938. Did you have any cases among the segregated people?—Not one, but I should like to add that we were very strict as far as that village was concerned. We burnt all the old clothing, and gave the people

new clothing and blankets, and also fed them for the six or seven days.

18,939. Were the persons who were segregated as contacts permitted to communicate with other infected areas in the pursuit of their ordinary avocations?—No.

18,940. In the village of Pali you adopted a different method, I believe?—Yes; there we had a different class of population to deal with.

18,941. What is the population there?—In Khari the population is mostly very poor, and consequently we could recompense them with money for their loss of labour; but in Pali the people are of a better class, and it was difficult to deal with them in a similar way. I think the population of Pali is about 600. There the people made a temporary hospital in the fields, and removed their sick to it, and all the people camped out of their own accord.

18,942. Did the people look after their own sick?—Yes.

18,943. How were the persons in segregation treated?—There was no segregation.

18,944. How long did it take for the disease to die out in this village?—I should think about six weeks.

18,945. Was there the same opportunity for communicating with infected places as at Khari?—Just the same.

18,946. Was the course of the disease the same?—Yes: it lasted about six weeks.

18,947. Have you any other village you would like to refer to? Danda, for instance?—In July we removed the people out of Dandâ, which is a village of from 3,500 to 4,000 people. About 1,500 came into Bandra. We took a census and kept them under surveillance, and within the next 10 days some of the people removed were attacked, but no cases occurred among the Bandra people in the neighbourhood.

18,948. Did you at any time during the epidemic at Danda have the contacts segregated for a certain time?—No. It was only in the village of Khari that we insisted upon segregation.

18,949. Is your experience that when you segregate contacts, but fail to keep a check upon the remainder of the population, that you put down the disease more rapidly than if you leave the contacts alone?—I do not think the disease is put down more rapidly, and I should not recommend the segregation of contacts.

18,950. Did you notice any mortality among rats before plague cases occurred in these villages?—Personally, no, but I had reports of it.

18,951. Did those reports satisfy you that mortality among rats occurred before there were any imported cases of plague?—Yes.

18,952. Do you feel sure of that?—Perfectly certain. During this present outbreak this year I have been taking particular notice of it. The village of Pali in this present month of February is an example.

18,953. Do you think that, prior to the mortality among rats in Pali, it was impossible for a plague infected person to have come from any outside area into that village?—No; it was quite possible.

Mr. E. F Allum.

17 Feb. 1899.

18,954. So that there may have been a person suffering in that village before the rats began to die?—They were mixing in the whole neighbourhood.

18,955. I mean that you cannot exclude the possibility of rats having been infected by some outside human being?—That is so.

18,956. Did you find that people wer as disinclined to give you information in the villages, as they were in the town of Bandra?—The people in the villages are more amenable. The smaller the village, the easier it is to get information, and the larger the more difficult; there is a general disinclination to give information.

18,957. In the villages you could get much more accurate information than in the town?—We find out cases in the villages more easily, but there is a general inclination to conceal cases.

18,958. Did they generally object to European treatment?—Yes; very few take this treatment. They are generally treated in the hospital by the native hakims.

18,959. Did you resort to disinfection in the villages?—Yes; in the village of Khari particularly.

18,960. What disinfectant was used?—We used perchloride of mercury for the interior of the houses, and carbolic acid for the narrow galis outside.

18,961. Did you observe that after a house had been disinfected, the people did not get plague in it, unless they had had opportunities for contracting it outside?—The people moved out of all the houses which were disinfected, and the houses were left vacant for several months afterwards.

18,962. Upon reoccupation, did cases of plague occur in any house which had been disinfected?—In Khari there were cases of plague last month in houses which were disinfected a year ago, and similarly in Bandra.

18,963. Might those cases have been due to outside disinfection?—Yes, it is quite possible.

18,964. You have nothing to show that the disinfection was inefficient?—No.

18,965. (*Dr. Ruffer.*) Do you know of any villages in which there has been an epidemic of plague among rats and not among human beings?—Yes.

18,966. Will you give us the names of those villages?—There is only one village where rats were reported to have died, and that is the village of Sherli. There was plague in the villages on each side, but Sherli escaped altogether.

18,967. How far off were the neighbouring villages?—Perhaps a quarter to half a mile apart.

18,968. At Kantwadi, Malla, and Rajan, you had very few deaths, I think?—Only five deaths.

18,969. There was a noticeable mortality among rats?—I do not know that the mortality was large. It is very difficult to get statistics about the numbers of rats. We get intimation that rates are dying and that is all.

(Witness withdrew.)

Mr. R. J. C. Lord, I.C.S., called and examined.

Mr. R. J. C. Lord, I.C.S.

18,970. (*The President.*) You were Assistant Judge at Broach?—Yes, and am now acting as Registrar of the High Court, Bombay.

18,971. (*Mr. Cumine.*) Where has your experience of plague been?—I saw a certain amount in Ahmednagar as Assistant Judge, and afterwards as Assistant Collector in charge of the Nagar taluka, and as Personal Assistant to the Collector I saw the reports concerning the whole of the district and had an opportunity of noticing their contents.

18,972. Is Nagar city a walled town?—Yes; it is a walled city which used to be the capital of the Nizám Sháhi dynasty.

18,973. What is the population?—Over 40,000.

18,974. Are the people crowded together?—Very crowded. The houses are closely jammed together. In one corner of the town you can see about an acre of flat mud roof with tiny openings in it. The tops of the houses are like a table, as it were, with large holes here and there, which are the only means of getting light and air.

18,975. While the people were in the town you had an establishment with a supervisor for every 100 houses in each ward and a certain number of Superintendents to look after the supervisors?—Yes; there were 12 wards.

18,976. And you had a Hospital Assistant to diagnose plague cases?—Yes; we had one, or at one time, I think, two.

18,977. Did this system enable the supervisors to become perfectly well acquainted with all the dwellers in their sections in a short time?—Yes, and thereby search parties were obviated.

18,978. Do you think it is a good thing that search parties should be unnecessary?—I consider search parties do a lot more harm than good, and should be avoided if the other system can be introduced, because a sick woman does not like to be looked at, even though she has not got plague. Nothing is gained by search parties which can outweigh the discomfort and disquiet they cause to the inhabitants.

Mr. R. J. C. Lord, I.C.S.

17 Feb. 1899.

18,979. After the occurrence of a certain number of indigenous cases in a ward, I think you evacuated that particular ward, did you not?—Yes, we turned them out by the agency of the police.

18,980. The result was that, by a certain time, the town was completely emptied?—Yes, fairly quickly.

18,981. I understand the people who went out of this town to live, and who were not taken to actual contact camps, lived in two kinds of camps, the Savedi health camp and another one?—Yes. The Savedi health camp was erected by the Municipality, and the other camp was made by the people themselves in the adjoining fields. It is hardly fair to call it a camp, because it just consisted of little huts dotted about in the people's own fields, especially where there was a tree, or well, or something like that.

18,982. Did you have any inspection of these people living in their own huts?—Yes, by the agency of the Abkari police.

18,983. Did you find many cases occurring among them?—Latterly I think there were a good many.

18,984. What did you do when several cases occurred?—We evacuated the field, and segregated everybody in the segregation ward of the Savedi camp. That was the first step in the way of segregation which was taken in the operations.

18,985. Did the infection appear to be brought from the town, or to spread from one hut to another in the fields?—I think it must have spread from one hut to another in the fields after having originally come from the town, because we found that one case in a mala or field was followed by several others. It was not as if the cases were sporadic, but one case nearly always brought on more in the same locality.

18,986. How did you manage with regard to weavers and other handicraftsmen who had to earn their bread?—If they would live in the Savedi camp, we allowed them to have a pass to take them by day into the city, returning at night. Thus we were able to inspect them every morning and evening.

18,987. Did you find that any of them caught plague by going into the town in this way?—Only one, as far as I can remember; that was a weaver who was taken sick at his loom. He died at once, and was buried by his sons in his back yard. He was missed that night, but owing to the ingenuity with which his grave was concealed, it was not detected for, I think, a whole day, though the house and vicinity were searched for it.

18,988. Did the cases appear to get milder towards the end of the epidemic?—No, they appeared to be of a more virulent type. That is simply my impression; it struck me that, as a rule, towards the end of the epidemic, when a man got ill of plague he died within a few hours.

18,989. Did you see any cases of black plague?—One or two were reported to me, but I did not see any myself. I believe that information regarding them can be found upon the record. There were returns of a case which occurred, I think, in Nagardeola.

18,990. Did any cases come to your notice where cats appeared to be attacked with plague?—Nagar was overrun with cats, and in the opinion of the Civil Surgeon there they did get plague. They were looking very miserable, with generally a pink line about their neck. Some were seen by the Civil Surgeon, I believe, in one particular quarter of the town running about with open buboes in their necks, and they were destroyed.

18,991. Do you know whether they were bacteriologically examined or not?—No, they were not, as far as I can remember. The great thing was to kill them and get them out of the way, to prevent the re-infection by them of the houses we had just disinfected. We did not go any further into the matter. The Civil Surgeon may know more about it, but I do not.

18,992. Were there many rats in Nagar?—Very few, perhaps on account of the number of cats.

18,993. Did the plague appear to take any particular course through the town of Nagar?—From east to west, practically, along the three main roads. It seemed to go by a line and then diverge and then pass out through the different gates. It passed in a very regular line, but I dare say that was owing to the fact that evacuation followed that line; but we did not find that the few people whose removal would have endangered their lives who were still allowed to remain got plague behind the line of march.

18,994. I suppose you treated the villages in much the same way as the town?—Yes, practically.

18,995. With all these people going out of Nagar town, did the people in the villages appreciate the danger of admitting refugees who might possibly be infected?—At first they did not; afterwards they did.

18,996. Did you find that although people might be averse to going out in the first instance, still when they had lived a little time in their huts they were perfectly willing to stay there?—Yes, they settled down to it more or less. Of course they preferred to live in the city. Until the middle of February they used to complain of the cold, and then in the third week of February they complained of the heat: it was only really that they preferred their houses; but afterwards, when it came to the time for closing the Savedi camp, there was a considerable difficulty in getting some of the people out of it.

18,997. Did you have many cases in the Nagar district of plague imported from Bombay not taking root in the Nagar district?—According to my recollection there were a great many such cases. So far as I can remember, I think there was only one case at Sathral, in the Sangamner taluka, from Bombay, which was followed by indigenous cases, but I am not certain if even it came from Bombay. Others may have occurred before my connection with plague operations, but I do not think they did.

18,998. Did you find that cases of infection imported from Poona seemed to take root more easily than imported cases from Bombay?—Very much more easily; in fact, I believe it will be found that every case imported from Poona or Sirur led to an outbreak.

18,999. Where did the infection come from to Nagar town itself?—It came from Nagar Cantonment, to which it came from Sirur. Sirur was between Poona and Nagar.

19,000. Where did the infection in the villages come from?—It mostly came from Poona, especially in the Parner and Shrigonda talukas, and to the best of my recollection a certain amount came from Igatpuri.

19,001. How was the infection taken from one village to another?—By sick people.

19,002. By human agency?—Yes.

19,003. How did it appear to be carried from one house to another within a town?—I suppose by human agency, but I must say that as far as I could see in big blocks of houses it did not pass from one house to other houses adjoining it in other streets (*e.g.*, touching back to back, with doors in different streets), but travelled up the street, *i.e.*, it probably was brought through the doors and not the walls.

19,004. (*Prof. Wright.*) Did it surprise you to find every case from Poona affecting the village?—That is more or less a generalization on looking back; I mean it did not strike me at first, and it was only latterly that I came to think about the matter. It did not attract my attention at the time.

19,005. Can you suggest any explanation of the fact?—No. My private opinion is that the bacillus from below the ghats had got to be acclimatized in a damp place, because Poona is a damp place, and so is Igatpuri, more or less, and then Sirur was a little drier, and so the infection was brought gradually to a place in a condition in which it could live. I believe the same thing has been noticed in the Broach district, because cases taken straight from Bombay to Broach did not seem to spread. But when cases were brought into Broach from Ankleshwar, which is just south of Broach, the plague spread at once. I believe there had been several imported cases from Bombay direct into Broach which did not spread.

19,006. (*Dr. Ruffer.*) How long does it take to go from Bombay to Broach?—Just one night.

19,007. How long to Ankleshwar?—Pretty much the same time. Ankleshwar is about 6 miles from Broach.

19,008. How long does it take to go from Ahmednagar to Bombay?—About half a day.

19,009. How long does it take to Poona?—A quarter of a day.

19,010. (*The President.*) Do you know what is meant by the "black plague?"—No. We called it "black plague" because the people used to turn black.

19,011. After death or before death?—They were black after death; I do not know when the exact change took place.

(Witness withdrew.)

The Hon. Mr. BHALCHANDRA KRISHNA, called and examined.

Hon. Mr. Bhalchandra Krishna.
17 Feb. 1899.

19,012. (*The President.*) You a Licentiate in Medicine of the Bombay University?—Yes.

19,013. And a practitioner here?—Yes.

19,014. You take much interest in the affairs of the Municipality?—Yes; I am President of the Corporation.

19,015. And a member of His Excellency the Governor's Council?—Yes.

19,016. What is your opinion as to the origin of plague in Bombay?—I believe that the theory that it was introduced by fakirs from Garhwal and Kumaun is not tenable. The theory advanced was that some mendicants came from that place and brought with them the poison of plague. I am not prepared to accept that theory.

19,017. Why not?—Because these people came all the way from the north, and they must have halted at different places. They must have gone to Nasik, where there was an annual fair where thousands of people had assembled. If they went there, they were sure to have given the poison to those people, because they were in contact with them. Nasik was not first infected; in fact, it was during the second epidemic in Bombay that some cases occurred in the Nasik district. If the theory be correct, then Nasik and the places where those pilgrims halted should have had the plague to commence with, whereas we find that it commenced in a certain portion of Bombay called the Port Trust Estate.

19,018. How long does a person take to go from Garhwal to Nasik, as a rule?—At least 8 days.

19,019. What view do you entertain as to the origin of plague in this city?—Another theory has been advanced that the plague bacillus was generated *de novo* in Bombay on account of the insanitary condition of those places where it first originated. My own view is that it must have been introduced into Bombay from Hong Kong—first on the Port Trust Estate. My reasons for holding that as a working hypothesis—I will not call it a theory—is this. If we trace the earliest cases of plague in Bombay, we find that about the 15th August cases began to appear; at least, they were noticed at that time, although they were not diagnosed as cases of plague, but as a peculiar kind of fever. The medical men who attended those cases were not in a position to exactly diagnose them. I am informed that the first case occurred in a house situated in Broach Street, in the Port Trust Estate, belonging to Mr. Rowjee Heerji. That is about the 15th August 1896. After that, very close to it, a case was noticed by a medical practitioner on the 21st August 1896. Near the house of Mr. Rowjee Heerji there is a godown belonging to Mr. Dhomo Narsi, situated in Surat Street, on the Port Trust Estate. Close to this house there is a godown of grain, and this godown abounds in rats. I believe that the first infection was communicated from those houses to the rats which abound in this grain godown, and from thence it spread. Even up to this time it is quite circumscribed and confined to one side of the Port Trust Estate. From thence it spread to the other side of the Mandvi Bridge, what is called the Argyle Road and Clive Road, where there is a large mala, called Vakhatna Mala, situated on Clive Road. Then it spread to a house belonging to Mr. Lakhamsi Napu. It is here that Dr. Viegas, who first diagnosed it as plague, found his first case, and he announced it at a meeting of the Standing Committee, of which I was the Chairman, on the 21st September 1896. The history of this case seems to be that Mr. Lakhamsi Napu had some labourers connected with his firm, and they were residing at a place called Marwadis' Mala, where the second case occurred on the 21st August. Two labourers from this Marwadis' Mala used to be associated with the nephew of Mr. Lakhamsi Napu, and all of them died of plague. My argument is this, that all this portion of the Port Trust Estate has godowns, where Chinese goods are stored. There are three on Argyle Road, where Chinese crackers are stored, and there are two or three on Broach Street and Surat Street, where Chinese sugar and Chinese silk are stored. Chinese crackers are generally brought to Bombay in the early part of July, or the beginning of August, and I believe that the infection must have been imported into Bombay by these goods. Crackers are used in August, and then again in November. For nearly a month plague was confined to these Estates only. It did not make its progress beyond Mandvi Bridge towards the city. It was after a month that it entered the city, and then it spread to all its parts. From these facts, I am inclined to believe that it was imported into Bombay from China.

19,020. What is your opinion as to the way in which the disease is communicated?—I believe it is communicated in several ways. The first and most important is by infected and dead rats. I have known of cases where dead rats have communicated the disease.

19,021. Can you give us an example of these?—During the first epidemic in 1896 I saw four cases where the people had handled dead rats; they developed plague and died.

19,022. How soon after handling the rats did they acquire the disease?—Three or four days.

19,023. Had these persons any opportunity of obtaining the infection elsewhere?—So far as I could ascertain, there had not been any other source of infection. Then another case occurred lately in a Parsee lady, near Girgaum. She was taking out rice for cooking, and a dead rat came on to the palm of her hand, and next day she got plague. She was under my treatment, and she died in three days.

19,024. Was there any injury on her hand?—I could not trace any.

19,025. How do you think she acquired the disease—by mere contact?—Yes.

19,026. Through the epidermis?—I believe so.

19,027. Through the uninjured epidermis?—I believe so, because there was no wound on the hand, so far as I could see.

19,028. Besides communication through rats, what other means do you consider may be operative?—I consider the locality is the most powerful source of infection, where dead rats were found. Even if the rats are removed that locality retains the poison, and that is a fruitful source of the disease. Then infected clothing is also a fruitful source. I have seen one or two cases of this, especially one very marked case. It was the case of a young man who, simply through hardihood, slept in the bedclothes where a patient had lain. One case was removed from the bungalow of the Honourable Justice Ranade. The boy was removed to the Hindu Fever Hospital, with which I am connected, and the boy who brought him to the hospital slept in his bed clothes. The result was that three days afterwards he had a very violent attack of plague, and he died on the third day, whereas the boy who was removed previously recovered.

19,029. Had not the boy who died any opportunity of coming into contact with the plague patient who had been removed, before he slept in these bed clothes?—He brought that first boy to the hospital, and there were others with him who were not affected.

19,030. I mean before this boy was taken to the hospital?—They were living in the same house. I made a note of this, because there were others who came with him who all escaped. They lived in the same house, under the same conditions, and they escaped; whereas this boy, in order to try the experiment, slept in the bed clothes one night, and on the third day he got attacked.

19,031. In addition to that, what other means of conveyance are there?—Contact with plague patients.

19,032. Do you think that this contact can introduce plague into the body through an unbroken skin? Have you any observations which bear upon that point?—I cannot distinctly say that, because it is a very disputed point; in fact, I think I have come in contact with plague cases several times myself, both in private practice and in the Hindu Fever Hospital. Although they are few, at the same time cases have occurred of medical men and ward-boys who were in contact with plague patients who have died of the disease. The medical man in charge of the Hindu Fever Hospital, after three months, all of a sudden, developed plague. So far as I could see, there was no injury to his hand or to his body, and there was nothing to account for it.

19,033. Did you search specially for any abrasions?—Yes; he was under my treatment.

Hon. Mr. Bhalchandra Krishna.

17 Feb. 1899.

19,034. You looked at the skin carefully with that object?—Yes, and so far as I could discover, there was nothing.

19,035. What kind of plague was it?—Ordinary pneumonic plague.

19,036. Further than that, do you think discharges from the patients might cause plague?—Yes; discharges from patients, especially patients affected with pneumonic plague, and their sputum. I have noticed cases occurring from the contact of discharges from the body of a plague patient after death.

19,037. What discharges?—Fæcal discharges, or urine, which, falling upon the corpse bearers, gave them plague. Amongst us, the corpse is borne on the shoulders of men; it is not carried in hearses, and so on, but the people carry the dead bodies. Some four cases came to my notice, where the discharge fell from the dead body upon the bearers, and gave them plague. Other cases must have occurred, but I only allude to those cases which I have seen.

19,038. Have you particulars of those cases?—One is a gentleman named Munshi. During the first epidemic in 1896, he assisted in carrying a dead body, and about four days afterwards he developed plague and died.

19,039. What is the evidence that any discharge fell upon him? How do you know that he came in contact with anything proceeding from the corpse?—There is no particular evidence to show that. I was not able to examine the body at the time.

19,040. Now, the second case?—The second case is of Mr. Lokhande, who was similarly infected, but I cannot give any positive evidence that the discharges fell upon his body. These people were not living in an infected place, and they were not living where dead rats were found, and they did not come in contact with any other plague cases except those dead bodies. That much I can say. I am not able to produce direct evidence as to discharge falling from the dead body.

19,041. What is your opinion as to the value of curative serums?—There are three curative serums which have been tried. With regard to Haffkine's curative serum, I think it failed. With regard to Dr. Yersin's, I saw one case which was treated with Yersin's serum and was cured. That was the only case of plague I saw cured by Yersin's serum. In order to give further trial to the serum, I requested Dr. Yersin, together with Dr. Blaney, to go round the Hindu Fever Hospital. He examined all the patients, and said that several patients were already recovering, so that there was no necessity to inject the serum. With regard to three cases which were almost moribund, he said it would not be advisible to waste his serum. But, fortunately, those three moribund cases recovered under hospital treatment, and a note has been made of that by Dr. Lowson in his report*.

19,042. The evidence which came under your observation does not show much?—No.

19,043. You have given a great deal of attention to the value of Haffkine's prophylactic fluid have you not?—Yes.

19,044. I believe you yourself have been inoculated?—Yes.

19,045. Will you describe to the Commission what effects the inoculation produced upon you?—I was inoculated twice, in February and March 1897. On the first occasion I was given 2 c.c., which was injected into my left arm. That was in the evening about 6 o'clock. I was able to attend to my work up to 9 o'clock. After that I had fever which lasted throughout the whole night, and my temperature rose to 101. I was restless all night and had disturbed sleep on account of dreams. I had copious diuresis and severe headache. In the morning I perspired, but I was able to take my bath and attend to my duties, only I felt exhaustion and inability to work.

19,046. When did the temperature go down?—In the morning. I had perspiration in the morning at 6 o'clock and the temperature went down, and I was able to take a bath.

19,047. Now with regard to the local phenomena?—There was swelling of the left arm at the seat of inoculation.

19,048. When?—At the same time that I had the fever, at 9 o'clock, and there was pain. The pain on the first day was not very severe, but on the second day I was not able to move my arm because it was painful. That lasted for three days and left a very thick nodule at the seat of inoculation, but no other symptoms. In fact, after three or four days I felt better than I had felt previous to inoculation. That is say experience of the first inoculation. In March I was inoculated a second time with 2½ c.c. and the symptoms were nearly the same, but on this occasion the temperature rose to 102, and I had disturbed sleep, as I have mentioned. There was no inconvenience of any kind. The sequence of symptoms and the effect on my body were the same as on the first occasion. Then I was inoculated again in February 1899, that is this month.

19,049. A third time?—Yes, about the commencement of February—and I had the same symptoms. I have yet a slight pain left in my arm, but beyond that there is no inconvenience. There is one thing I noticed, and that was a little erysipelatous inflammation running down the lower portion of the arm to the elbow. Beyond that I had nothing to complain of.

19,050. There was no diminution in the severity of the symptoms in the subsequent inoculations?—There was no diminution.

19,051. Is it in conformity with your general experience that the injections have not done much harm?—I have seen several cases, and so far as I have been able to gather it has not done much harm in the majority of cases. I have come across cases where it has produced general malaise, inability to work, or very slight rise of temperature; but beyond that I have not come across any case in which it has produced absolutely serious symptoms. There is one case which I must place before the Commission, and that is the case of a Khoja girl who was shown to me six months after inoculation. She is about 12 years old, and her parents told me that she developed the symptoms a month after inoculation. Those symptoms were the second stage of phthisis. The girl is living now. I treated her and she is all right. I must mention that the family has an hereditary taint of phthisis. Her elder sister died of consumption, but the parents said that this girl developed the symptoms after inoculation. This is a case which occurred in my practice and I must mention it, but I am not prepared to believe that the symptoms were due to inoculation. Very likely if the girl had not been inoculated she would have developed the same symptoms. There is no evidence to show that it was the inoculation which brought on the symptoms. I referred the case to Dr. Haffkine and he also agreed with me.

19,052. Have you been able to follow the after-history of many of the cases which have been inoculated?—Yes.

19,053. Have many of them died to your knowledge?—I have known of one case personally which succumbed after inoculation. It was the case of a Vakil, a strong young man who was living in a house where dead rats were found. It seems that he felt symptoms of fever and plague coming on, and ran up to Bombay to get himself inoculated. On the same day he returned to Thana, and developed very severe plague and died. This is the only case which came to my notice.

19,054. To what do you attribute the plague in this instance?—I attribute it entirely to the previous infection, and not to inoculation. This case has been made much of by the opponents of inoculation, but I know the circumstances thoroughly, and the Commission may take them for what they are worth. The second case is of a Parsee boy, but that was not in my practice. He died after inoculation, but I do not know the circumstances of the case.

19,055. On the other hand have you observed any good effects, outside of the prevention of plague, to follow inoculation?—Yes, I have come across some cases. I mentioned those in a paper which I read in November 1898 before the Grant College Medical Society on M. Haffkine's prophylactic inoculations as follows:—"In certain cases inoculation has undoubtedly produced a beneficial effect on the general health of the inoculated. I have personally seen two cases in whom the anti-plague inoculation produced remarkable results. A medical gentleman, whom many of you know, and who was habitually strong and robust, began, some time back, to lose flesh and strength, and in the course of some months became anæmic and weak. An eminent

* Report on the Epidemic of Plague, from 22nd February to 16th July 1897, by James A. Lowson, Plague Commissioner, Bombay.

physician of our city whom he consulted, pronounced him to be phthisical, but he was not supported by another, also a very competent gentleman of the profession, who declared that he was suffering from an exhausting disease, the nature of which he was not able to diagnose definitely. The patient was treated, but without any beneficial results. While in this condition he was advised to get himself protected against the plague. The result upon his general health was most striking. He began to improve almost immediately after inoculation, and in a few months gained up to 15 lbs. in weight. He dropped all other treatment, and has now completely regained his health and weight. The second case which came within my own observation, is that of the wife of an eminent citizen of Bombay, a Hindu additional member of His Excellency the Governor's Council. She was suffering for a long time from intermittent fever which was not amenable to any treatment. When the rest of the family was inoculated against plague she was inoculated too, at first cautiously, and then with another dose. The two inoculations had the unexpected effect of subduing entirely her habitual fever. Prof. Haffkine has kindly placed at my disposal four other cases of analogous nature. One is the case of Mr. K., residing at Nepean Sea Road, Bombay, who was suffering for a long time from a daily rise of temperature which defied all treatment. Mr. K. desired to undergo inoculation against plague, and requested Dr. Temulji B. Nariman, his medical attendant, to consult Prof. Haffkine. The answer was :—" It is advisable to abstain from inocula- " tion in cases of acute or sudden attacks of fever " the nature and the issue of which is not taken, but " there is no contra-indication in cases of chronic " fevers; only the inoculation should be done in such " cases with reduced doses." Under this advice Mr. K. underwent inoculation by Prof. Haffkine himself, with the result that the inoculation produced the usual rise of temperature, which subsided within 24 hours; but with that Mr. K.'s usual fever was entirely cured. Prof. Haffkine visited the gentleman a fortnight later, found him in perfect health, and inoculated him again with the full standard dose, to which he re-acted as a perfectly normal case. The other cases were those of Captain MacDonald, I.M.S., and his servant, who were suffering from continuous attacks of malarious fever defying all treatment. They were inoculated against plague with the result that their chronic fever left them entirely. Another similar case is that of Dr. K. N. Gokhale, L. M. and S., Chief Medical Officer, Bhor State. Dr. Gokhale, when he first joined his appointment, suffered from fortnightly attacks of fever. When plague broke out in the State he went to Poona and got himself inoculated in the David Sassoon Hospital. From that time he never had another attack of fever." These and other similar cases to a great extent bear out Prof. Haffkine's view that the inoculation against plague seems to influence favourably the resistance to some other diseases than plague, and especially fevers.

19,056. Will you state generally the result?—The result has been beneficial in those cases, although the inoculation was not done with the object of curing them, but simply as a preventive of plague. In the case of the Parsee gentleman whom I have mentioned, he was a medical man himself, suffering from a wasting disease, and the physicians of Bombay were not able to diagnose his case. Some said it was phthisis, and others said it was a wasting disease.

19,057. It was a vague affection?—Yes.

19,058. What were the others?—They were malarious fevers. They have distinctly been benefited. There was the case of a friend of mine, a member of Council also, and his wife. She suffered from malarious fevers and she was inoculated for plague, and the result has been that she has shaken off the fever.

19,059. Have you never found cases of malarial fever recover rather unexpectedly?—They do.

19,060. Likewise in cases of vague illnesses, such as a wasting disease, sometimes a most unexpected improvement takes place?—That is so. I have said that it may not be due to inoculation.

Hon. Mr. Bhalchandra Krishna.

17 Feb. 1899.

19,061. Have you had much experience of the effects of the prophylactic in actually preventing plague?—Yes.

19,062. Under your own observation?—Yes.

19,063. Have you the statistics?—I have mentioned them in the pamphlet* which I have put in as an accompaniment to my précis of evidence.

19,064. Have you any collection of cases?—I have collected a few cases.

19,065. Will you put them in and tabulate them?—I have not put them in tabular form, but they are all included in these statistics.

19,066. Individual cases are not likely to be of much value unless they are very definite. Are there any which you would like to state particularly?—I will mention two or three cases. For instance; in the family of a Parsee friend of mine several members were inoculated. He was living at Parel. His servants, some four or five Bhyas, refused to be inoculated, and when plague spread to Parel two of those four Bhyas died. Then the remaining two insisted upon being inoculated, which was done, and they did not get plague. Then in the case of a Muhammadan friend of mine, also a member of the Governor's Council, all the members of his family were inoculated, but some three servants refused to be inoculated. During the first epidemic those three servants succumbed, while all the rest escaped the disease. In another family, in the same way all the members were inoculated except one girl, and that girl died, while the others escaped. These cases I mention for what they may be worth.

19,067. (*Mr. Hewett.*) What were the main types of the disease in the three different epidemics?—Firstly, bubonic plague, then pneumonic plague.

19,068. When was that?—That was in the second epidemic.

19,069. Did this type prevail throughout the second epidemic?—It was in the middle part of the second epidemic.

19,070. Can you give us the months approximately?—I think it was in the months of February and March.

19,071. What is the chief type of the third epidemic?—The third type has been almost pneumonic; it is a mixed type. Sometimes there were not enlarged glands at all, but simply fever and delirious symptoms, but in others only the pneumonic type.

19,072. What is it mainly at present?—At present it is bubonic.

19,073. Is it very fatal now?—Yes, it is.

19,074. Is the bubonic form now more fatal than it was in the first epidemic?—Yes, it is.

19,075. Have you noticed any instances of people catching pneumonic plague from a bubonic patient?—No.

19,076. Have you noticed any cases of people catching bubonic plague from a pneumonic patient?—No.

19,077. (*Dr. Ruffer.*) Do you think a great many of the patients in this epidemic get lung symptoms?—Yes.

19,078. Do you consider that a bad sign in plague?—I do.

19,079. With reference to the case that travelled up from Thana in order to get inoculated, how long afterwards did he get plague?—Six hours afterwards. He was inoculated, and immediately developed plague after going to Thana.

* Not published in the Proceedings of the Commission.

(Witness withdrew.)

Dr. D. A. D'Monte called and examined.

Dr. D. A. D'Monte.

19,080. (*Mr. Cumine.*) You are a non-official, I think?—Yes.

19,081. You are Vice-President and Plague Authority at Bandra?—Yes.

19,082. I think that Bandra has had an epidemic of plague during each of the three last years?—Yes.

19,083. Can you say which of the epidemics was the worst?—The first one was the worst; but the third one is not yet finished.

19,084. I mean with regard to the virulence of the germ?—This one, I think, is more virulent.

19,085. Was the second one milder?—It was mild, I think, compared with the others.

Dr. D. A. D'Monte.
17 Feb. 1899.

19,086. In your précis of evidence you mention that the first case during the present epidemic occurred in a hut where the first imported case from Bombay died in 1896?—Yes. This seems to show that the germs remained dormant for a period of 24 months.

19,087. Might not the present infection have been imported from outside by the person attacked?—I do not think so. This was an indigenous case; it occurred in a person who never went to Bombay, and could not have got the infection from elsewhere.

19,088. Had anybody from an infected place come to him?—I do not think so.

19,089. Had there been any cases in this hut in the previous epidemic?—Not in the second epidemic.

19,090. Have you noticed whether, in the succeeding epidemics, the cases seem to occur in the same houses?—Yes.

19,091. Do they occur in those houses only?—They occur in other houses as well; but, generally, in those houses where plague occurred in the first and second epidemics, cases have occurred again this year.

19,092. Are you able to say that the infection was not brought from other houses into these houses in the present epidemics?—In some cases they were not brought from other houses.

19,093. You think it was a resuscitation of the old germs in the house itself?—Yes.

19,094. How are you able to say positively that in certain cases there was no re-infection from other houses?—I could not say positively.

19,095. You mention, in your précis of evidence, two cases of buboes in cats, and also fowls getting plague. How do you know the fowls had the plague?—Because just before some cases occurred in some of the houses in a village, lots of fowls died.

19,096. How do you know that they died of plague?—Because they actually had buboes in the neck and groin.

19,097. Have you any instance where a person has certainly caught plague from clothing?—No.

19,098. Have you any instance where persons caught plague from an article of food?—No.

19,099. Have you any instance where people have caught plague from the corpse of a person who has died of pneumonic plague?—Yes.

19,100. Is it within your knowledge that the people living on the ground floor of houses are more susceptible to the disease than those living in the top floors?—Those living in huts and on the ground floors are more susceptible.

19,101. Is the nature of the floor different in the ground-floor rooms from what it is in the upper rooms?—The top floors are made of wood, and the ground floors are of earth.

19,102. When people live in sheds in the fields, does the plague spread much from hut to hut, or only a little?—Only a little.

19,103. Have you had any experience of inoculation with Prof. Haffkine's prophylactic serum?—Yes.

19,104. How many cases have come under your notice?—About 27.

19,105. Did you observe any bad effects in any cases?—In one case. That was not inoculated by myself, but by Prof. Haffkine himself.

19,106. What was the bad effect?—I did not mean a bad effect of inoculation; but this man was inoculated, and he got a bubo after inoculation, and died.

19,107. Did you see him?—Yes.

19,108. Have you any instance where a man has caught plague three times?—There is one case.

19,109. Did you see the man each time?—Yes.

19,110. What was the interval between the three attacks; could it not have been a relapse?—Three months the first time, and six months the second time.

19,111. (*The President.*) We had better have the exact date of each occurrence?—I have not them here, but I will give them. (Witness intimated later that he was not able to get the exact dates.)

19,112. (*Mr. Cumine.*) How many cases of Haffkine's curative serum have come under your notice?—Four.

19,113. What happened in each case?—They all died.

19,114. How many instances of Yersin's serum?—One, and that patient recovered.

19,115. How many cases of Lustig's serum?—Two, and both recovered.

19,116. (*Prof. Wright.*) Did you examine those fowls which died of plague?—Yes.

19,117. How many *post mortems* did you make?—I did not make any. I saw the fowls myself.

19,118. How did you see they had buboes?—I could feel them.

19,119. How many buboes had each fowl?—Some had one, and some had two.

19,120. They were not examined bacteriologically?—No.

19,121. In the case which you report, in which a man had plague three times, can you tell us whether he had buboes each time?—The first time he had a bubo; the second time he had no bubo; and the third time he had a bubo.

19,122. How was it known that he had plague a second time?—He had a very high temperature, rigors, and drowsiness—the same symptoms, almost.

19,123. Where were the buboes in the first and third times?—In the groin, both times.

19,124. The same groin?—Yes

19,125. Did he recover from the third attack also?—He died of the third attack.

19,126. (*Dr. Ruffer.*) What class of people live in the ground floor, as compared to top floors; are they a better class of people?—No, they are poorer.

19,127. (*The President.*) To what do you attribute the difference; how do you explain the difference in mortality in the ground floors, as distinguished from the higher floors?—To the dampness of the floor.

19,128. Is there any difference in ventilation?—Yes; the top floors are better ventilated.

19,129. The conditions there are, in that respect, similar to those which prevail in the huts in the fields?—Yes.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

FIFTIETH DAY.

Saturday, 18th February, 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S., (*President*).

Mr. J. P. HEWETT.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Dr. C. H. FREEMAN UNDERWOOD called and examined.

Dr. C. H. Freeman Underwood.

18 Feb. 1899.

19,130. (*The President.*) You are a doctor of medicine, I think?—Yes, and a licenciate of the King's and Queen's College of Physicians, Ireland.

19,131. Have you any official position in regard to plague?—No. I am in private practice in Bombay.

19,132. (*Dr. Ruffer.*) Can you give us any evidence as to the origin of plague in Bombay?—To the best of my knowledge the plague has been in Bombay in 1690, 1700, and also in 1804–5.

19,133. I mean the present epidemic?—In the epidemic of 1896 my initial cases were observed in the latter part of July or the early part of August 1896. Following on these I managed to obtain three photographs which I took of what appeared to me a peculiar type of disease. Two were natives, and one is an European.

19,134. When were these photographs taken?—These were taken as soon as I saw the cases in the latter part of July, or early days of August 1896. The generality of the cases I observed were rapid in incidence and fatal in termination without glandular developments; the course of the disease being terminated within 24 or 48 hours of its incidence. Following on these I managed to obtain photographs of three peculiar cases, two natives and one European, the former being cases of bilateral parotid enlargement, an intumescence of the thyroid gland and the tissues of the neck, the pharynx and tonsils being deeply injected, and aphonia, *tinnitus aurium*, and occasional flashes of light before the eyes being complained of; the maximum temperature in the Muhammadan case was 104·8, whilst the Hindu showed 105-F; both recovered.

19,135. I want to know first about the cases which terminated fatally in two days. First of all what evidence have you got to show that they were cases of plague?—From the rapid course, and, to say the least, the unique and peculiar clinical features of these cases, I was led to diagnose them as *typhus siderans*. No previous cases had been reported, and as it was very obscure at the time I put these down as *typhus siderans*.

19,136. What evidence have you got to show that these were cases of plague?—The rapid course, the high fever, and the glandular enlargements. My subsequent experience of plague proved beyond doubt that they must have been cases of plague.

19,137. Why?—Because you get, even in the present day, cases that commence with very high fever. The nervous system seems completely to be shattered by the virulence of the poison, and in fact sufficient time does not remain for the development of glandular enlargements.

19,138. But do not you get similar symptoms from other microbes, for instance in septicæmia from post-mortem wounds?—In such cases there is always the history of pre-existing wound infection.

19,139. Did you look for an infection wound?—Yes. It was said here by some medical men that the glandular cases were generally the result of infection.

19,140. I am not speaking of the glandular cases; I am speaking of the other cases?—I have not been able to trace any infection through external wounds or abrasions.

19,141. The only evidence you have got that these cases were plague was the presence of profound intoxication?—Yes, and that they died quickly.

19,142. You made no bacteriological examination of the rapid cases?—No, not of rapid cases. When I saw them coming on I made bacteriological examinations, I made an agar culture, and I then found the plague bacillus.

19,143. What month was that?—It was September 1896, or the latter part of August. The cases were not so numerous.

19,144. You did not make any bacteriological examination of these rapid cases in July or August?—No.

19,145. When was the first case in which you made a bacteriological examination?—I cannot rely on it, but I believe at the latter end of August.

19,146. There you found the plague bacillus?—Yes.

19,147. Did you recognise it at the time?—Yes.

19,148. Did you notify it to the authorities?—Having no voice in the councils of the city, I sought the Health Officer, but on each occasion missed both him and his Assistant, in consequence of their multifarious duties demanding their presence elsewhere, and it was left to Dr. Viegas to bring the matter before the Standing Committee of the Municipal Corporation.

19,149. Have you seen similar cases since?—Very many.

19,150. Now you are able to diagnose them as plague cases?—With certainty.

19,151. Are these acute plague cases which you observe now similar to the cases which you saw in July, or do they differ in any way?—They seem very similar and present the same acute septicæmic intoxication.

19,152. Can you give us an account of the acute symptoms noticed by you in July?—I was called to see these patients when they were suffering from high fever. Many of them were in a comatose condition, some of them with a low muttering delirium: others could be roused when loudly called to, relapsing again into this apathetic, or semi-conscious state; the fever ran high; there were no glands at the time, and there seemed to be no pulmonary, cardiac, or any other complication as far as could be made out. Some of them had bronchitic complications, but nothing much to speak of.

19,153. Did you examine the eyes?—Their eyes were injected.

19,154. What was the tongue like?—Coated and dry.

19,155. You held no *post-mortem* examination?—No, it was impossible, as a private practitioner, to do so.

19,156. Can you tell me where these cases occurred; in a certain district, or scattered through the town?—In a certain district—in Mandvi.

Dr. C. H. Freeman Underwood.

18 Feb. 1899.

19,157. At that time, had you already found dead rats at Mandvi?—It was I who first drew attention to the rat mortality.

19,158. When did you first draw attention to the mortality among rats?—In 1896.

19,159. What month?—I believe in the month of September. Previous to that rats died here and there, but in September, when the plague increased in virulence, rats died in very large numbers.

19,160. In all bubonic cases you observed in July or August, in what part of the body were the buboes?—The larger percentage was in the right inguinal.

19,161. The photographs you have shown us are mostly cases of cervical enlargements?—Yes, but those were seen by me also about the early part of the epidemic of 1896.

19,162. When did you observe these cases of enlargements in the neck?—I believe in August, I am not quite sure.

19,163. When did you see the cases with enlargements in the groin?—In the latter part of August and September.

19,164. How are you certain that these cases were plague and not enlargement of the glands from other causes?—From the rapid incidence of the disease, the high temperature and the absence of any syphilitic or other contamination.

19,165. Anything else?—The dirty and filthy condition of the houses that they lived in.

19,166. Did these cases terminate fatally, or did they not?—Not all.

19,167. What was the proportion?—In 1896 I was fairly successful.

19,168. About how many cases did you see in August?—Between 10 and 15.

19,169. How many died?—Most of them died.

19,170. Did you notice any cases of pneumonia at that time?—I did. I was the first who drew attention to that in Bombay.

19,171. In August?—No, in September.

19,172. Did you consider these cases of pneumonia at that time as plague, or as ordinary pneumonia?—I had my suspicion that it was not the ordinary pneumonia on account of the very exaggerated symptoms and the rapid development of hæmorrhagic expectoration.

19,173. In the cases of pneumonia did you find bubonic cases in the same house?—I cannot say that I did.

19,174. Did you ever see several cases of pneumonia occur in the same house at that time?—I have noticed as many as two, not more.

19,175. Were these cases in the worst part of the town?—At Mandvi. There is very little to choose between the worst parts.

19,176. They are all bad?—Yes.

19,177. (*The President.*) Was it in the worst part of Bombay?—Yes, Mandvi is a very bad part. It was built on the former sweepings of the town.

19,178. (*Dr. Ruffer.*) How do you think the disease got into Bombay? Have you any facts bearing on that?—Yes, I believe that the disease has been hanging about Bombay, on and off, for some centuries.

19,179. What facts have you observed to make you think that?—I quote from authorities.

19,180. I do not want quotations, I want facts. Did you ever, before July, 1895, see a case of plague, or a suspicious case of plague?—I could not say that.

19,181. Do you know any medical man who has seen a case of plague, or anything like plague during that time?—I do not think so. There is a medical man in Bombay, who, I believe, saw cases; on my asking him to give his evidence here, he replied that he "did not care to waste his time—his time was too valuable."

19,182. Then you have practically no evidence on that point. Have you any other reasons for thinking that plague was present in Bombay?—Not recently, not within any short period before its development in 1896.

19,183. Say within the last two years before 1896?—I have evidence of it being here in 1804 and 1805, when it ruined the city completely.

19,184. Within the last 10 years?—No, not within the last 10 years.

19,185. Do you think the disease was imported into Bombay?—No, I do not.

19,186. Why do you think that it was not imported?—Because there is a history of it having been about Thana Daman and Bombay before, extending over a period of two centuries.

19,187. I mean within the last 10 years?—Not within the last 10 years. The last I heard of it was in 1836 and 1837, in the Jodhpur State and at Pali.

19,188. Have you any evidence to show that plague was present in Bombay or parts round Bombay between 1836 and 1896?—I have not, but what I would wish to suggest is this: that the microbe has been in the soil.

19,189. Have you any facts to show that the microbe was in the soil?—The rat mortality points to that.

19,190. The rat mortality broke out after you had seen suspicious cases of plague. Have you any other facts to show that the plague bacillus was present in the soil in India between 1836 and 1896?—No, I have not. The rat mortality was coincident with the appearance of plague.

19,191. Can you give us some information as to the course of the disease?—The disease was spread by human agency chiefly. Mandvi is a business centre, and many people from various parts of the town find employment there during the day. It being at that time an infected spot, it is possible that they may carry away the poison in their systems to the other localities of the city, and there, after the period of incubation had been completed, the disease developed itself. It spread first in a westerly, then in a southerly, and lastly in a northerly direction.

19,192. How do you know that?—The spread was slow, and I traced it on to Bhuleshwar and Girgaum, and other parts of the town.

19,193. How do you know that there were not other cases in other parts of the town? All you know is that there were certain cases in that direction, but when you say it spread in one direction you mean that it spread in that direction alone?—We get the mortality tables from Dr. Weir.

19,194. We have had the tables from Dr. Weir. You have no other facts?—No.

19,195. In your précis, you say you think there were "influences, meteorological and telluric, which acted as "determining factors on the disease"?—We had a water-logged soil which was consequent upon the heavy monsoons that we had, and an obstruction at the outfall of the sewage system, which led to a damming up of the whole of the sewers and overflow of the sewers on to the low lying districts of the town. Add to this, the retention in the soil of the balance of 10 million gallons, the daily water supply of the city, and the water-logged condition is accounted for.

19,196. What evidence have you got to show that these conditions would spread plague, or would influence plague in any way?—The soil pollution and dampness would influence the development of the plague bacillus.

19,197. Why?—Because an organically polluted soil is a very favourable medium on which to grow any sort of bacterial entity whatever.

19,198. Have you any other reason to believe that the sewage or damp contaminated soil would spread the plague?—The exhalations from these polluted areas of course would vitiate the atmosphere and be determining influences, especially where the air was bad in stagnated localities—from aërial stagnation.

19,199. You think overcrowding would act in the same way?—Yes.

19,200. Do you think it would act in any other way?—It would lead to a vitiation of air, and the air would be re-breathed. It would have a devitalising influence on the human economy, and render it prone to the inception of any disease whether zymotic, or other.

19,201. Could you give us any evidence as to the pneumonic form spreading plague? Have you noticed that the pneumonic form is more contagious than any other?—I have.

19,202. Could you give us any facts, for instance, instances where there has been several pneumonic

cases in the same house or in the same room?—In the same room, yes; but I have not got the facts.

19,203. You have seen that?—I have seen two cases in the same room develop one after the other, first the son and then the mother was attacked.

19,204. That is one case; can you give us the others?—I cannot isolate them now.

19,205. Have you seen pneumonic or bubonic cases occurring in the same house?—Yes.

19,206. Could you give us examples of that?—In the same room in the same house? I could give you numerous examples. Had I known before, I could have given you the numbers of the houses in Mandvi that have developed and redeveloped plague in each epidemic.

19,207. That is not what I mean. Have you ever seen it in one family; at one and the same time, one person with plague pneumonia, and one or two or more persons with glandular disease? Can you show, for instance, that a person got bubonic plague from a pneumonic patient?—I could not trace the connection.

19,208. Can you trace the connection where a person got pneumonic plague from a bubonic patient?—I cannot.

19,209. Have you any example showing that a bubonic patient got bubonic plague from a bubonic patient?—Yes.

19,210. Can you give us some examples of that?—There is a case down at Abd-ul-Rahman Street. A boy, aged 14, was attacked with bubonic plague. He had four buboes, two on the right side and two on the left, in the groin, out of which the one on the left groin suppurated, and the entire gland was discharged. On account of the acuteness of the inflammation it was thrown out. Subsequent to that the mother got attacked, and then the aunt got attacked.

19,211. How long after the first attack?—I should say about a fortnight or three weeks.

19,212. She might have infected herself from someone else?—She was in attendance on the boy while he was ill. I do not believe she left the house; and in that very house there were eight or ten cases.

19,213. Did the boy die?—No; he is alive now. He had a temperature of 108½°.

19,214. Might she not have infected herself from the eight or ten cases?—They were subsequent to the mother.

19,215. In that house did they all have the bubonic form?—All bubonic; not a single pneumonic case.

19,216. Did any of the cases die?—Yes, several of them.

19,217. (*The President.*) Did this house consist of one or several chambers?—Several chambers.

19,218. (*Dr. Ruffer.*) What do you consider is the most infective form of plague?—The pneumonic.

19,219. Why do you think the pneumonic form is the most contagious?—For the simple reason that I have seen this one particular case occur, and I believe that it was owing to infection hanging over the patient. Then there is the case of Dr. Manser; he got the disease from a pneumonic case.

19,220. In all these cases the pneumonic form always produced another pneumonia case?—Yes, as far as I know.

19,221. The bubonic form must be infectious too?—Yes, but not to the same degree as the pneumonic form.

19,222. Why do you think the bubonic is not infectious? You have only given us two examples?—There is the case of the English nurse in Poona, who was attending a case.

19,223. We have had that case. Have you any others under your own observation?—No, I cannot mention any.

19,224. Do you think rats have much to do with the spread of plague?—I do.

19,225. Could you give us any facts bearing on that?—Rats, being dirty feeders on organic débris of every description, especially in damp localities with organic pollution, where conditions are favourable for the development of the lower grades of organic life, are from their peculiar proclivities prone to bacterial and other infection. In the recognition of a rat mortality as a criterion of an infected or plague area, the fact of their tenacity for life and well-being must not be overlooked, and a sudden exodus to other localities has followed.

19,226. How do you know that?—I have seen them.

19,227. Have you seen an army of rats walking about from place to place?—People have told me. At one period of the plague there were no rats at Kolaba.

19,228. Who told you?—Mrs. Guidera, who got the plague.

19,229. Did you observe these facts yourself or is it only hearsay evidence?—Some I have observed, and others I have been told by my patients.

19,230. How do you know there were no rats in the place?—She said there were no rats, and she was surprised to see rats in the garden. Subsequently to that dead rats were found in her house and she got plague.

19,231. That does not show that there was an exodus. It simply shows that dead rats were found in the garden. You say they migrate from place to place. What facts have you got to show that?—People themselves have told me. They say the moment plague occurs in a house every rat leaves the place; they were found on the opposite side of the street where they were not before.

19,232. How do you know they are the same rats?—It would be very difficult to say.

19,233. How do you know, for instance, that the rats who lived on the left side of the street went over to the right side of the street?—Generally the sides that are infected are deserted by rats.

19,234. That simply shows that the rats have died?—Not necessarily.

19,235. That is one explanation?—No; they carried the infection from here to Bandra.

19,236. You say that you know rats migrate from the side of the street because people told you on the other side of the street that the rats were there, and none were seen on this side of the street. That does not show that the rats on this side of the street went to the other—at least it does not in my opinion?—It is very difficult to observe each individual rat.

19,237. I quite agree with you. I want to know how you can say there was an exodus of rats, and that the rats migrate from place to place?—Because I have seen them travelling over the causeways. I heard that they were migrating and I went to verify the fact.

19,238. Have you seen them travelling along the streets?—Yes, I have seen them running along the causeways.

19,239. Have not you seen them before the plague occurred?—I cannot say I ever went to see them then.

19,240. Your attention was drawn to it, and then you observed them going across the street. Have you any evidence that more rats travelled across the street during the epidemic than before?—It is impossible for me to know that.

19,241. What other evidence have you got to show that rats migrate from place to place?—They were found in localities in which they did not exist previously.

19,242. How do you know that?—Because people have told me.

19,243. But is it not the fact that when rats are dying of plague they, in a dazed condition, leave their holes, so that more would be seen than in ordinary times?—I was the first that pointed that out. They were in a state of plague intoxication and they did not care where they went; and they did not seem to notice human beings if they came near them or even kicked them.

19,244. Would not that account for the fact of their being seen in places where they never have been seen before? Take Watson's Annexe, for instance? I have never seen a rat there; but supposing rats got plague in Watson's Annexe, I should probably see them, because they would come out of their holes. You, yourself, have observed it. Would not that account for the fact?—They seem to die so rapidly that a few hours finishes them off.

19,245. Does not this simply show that the disease is very contagious? Does the fact of a rat being seen where it never was seen before show that it comes from another place?—Not necessarily,

19,246. Have you any other facts to show that rats migrate from place to place?—I have noticed them, as

Dr. C. H. Freeman Underwood.

18 Feb. 1899.

I said, travelling across the causeways during the still hours of the night, when traffic was suspended. They have, in some instances of the occurrence of plague on the lower floors, escaped to the higher ones, and even across the streets to other, and, to them safer, localities.

19,247. I will put it in another way to you. Do rats get on board ship?—They do in the usual course, but since 1896 they have been practically exterminated in the locality of the docks.

19,248. Are not you losing a good many rats now in Mandvi?—Occasionally in the town, but not about the granaries, as formerly.

19,249. There are no rats there?—Very few.

19,250. If rats carried the disease, how do you account for people on board ships not getting the disease? Are not rats continually going from ships ashore, and from the shore on to the ships?—The docks are kept particularly clean, no organic débris lying about, and no filth, of any description.

19,251. What was the causeway where you saw the rats?—The Mahim Causeway and the Sion Causeway.

19,252. Is that near the harbour?—No; on the other side of the city altogether.

19,253. Have you any other facts to show that rats spread the disease?—The disease has invariably occurred where rats have been found dead—within, at least, 60 to 80 per cent. of cases.

19,254. Anything else?—Under favourable conditions I have noticed that the bacillus has steadily increased; and if you keep the rat at a warm temperature, you find that the bacillus increases for the first 24 hours in the body of the rat: afterwards there is no increase.

19,255. It multiplies?—Yes.

19,256. Anything else?—No.

19,257. Can you give us any facts showing that plague is carried by air?—People from different parts of the city have always worked at Mandvi during the greater part of the day, it being an important business centre, and used to have their meals at their homes. They used to be at Mandvi during certain hours of the day, and only those hours. After that they used to go home, and it was not possible that otherwise than through the air they imbibed the disease; because many of them had no wounds, and to all intents and purposes were in perfect health, and perhaps within two or three hours after their return home they developed plague.

19,258. Have you any other facts besides that?—There was the case of the very first European that got plague, Mr. Orford Sherman. He had been photographing the cases at Mandvi, and subsequent to that he developed plague, and died of it.

19,259. How does that show that he got it through air?—He was otherwise perfectly healthy; a man at his business.

19,260. You have no other facts?—No.

19,261. I believe you have done a good deal of inoculation work?—Rather more than 2,000 cases.

19,262. Did you take the temperature of these cases?—Previous to inoculation, yes.

19,263. After inoculation?—I had no opportunity.

19,264. Did you ever see any evil effects from inoculation?—I cannot say that I have seen any evil effects.

19,265. Have you ever seen any abscesses?—Not as a result of my inoculation, but from neglect of due asepsis.

19,266. Have you ever seen very high temperature after inoculation?—Yes; 105°.

19,267. You said just now that you took no temperatures after inoculation?—The patients told me.

19,268. Did they take their temperatures themselves? Yes.

19,269. Have you any other evidence as to the rise of temperature?—The majority of them came round, and told me it was about 102, 103, and so on.

19,270. How did they know?—The Parsees are an educated class.

19,271. You refer specially to the Parsees?—Yes.

19,272. How did you standardise the dose you used?—I judged the dose according to the individual I had to deal with, rejecting those in whom I found an increased temperature.

19,273. You said you took no temperatures?—Previously to inoculation I did.

19,274. Previous to inoculation; but we have been told that one way of standardising the prophylactic fluid is to take the temperature of a certain number of people after the fluid has been injected. I understand you did not do that?—It was not possible.

19,275. How did you judge the dose you were to use? For instance, supposing the Plague Commission came to you to be inoculated, how would you judge what dose you were to give each Commissioner?—It would be the case of the eminent French physician, who judged according to the exigencies of the hour, and the individual susceptibilities of his patient.

19,276. But you could not possibly know the individual susceptibility of the 2,000 persons who came to be inoculated?—It is impossible to judge idiosyncracies.

19,277. Supposing 100 people presented themselves, how would you judge the dose you inoculated into each one of them: did you inject all with the same dose?—No.

12,278. What guided you in the choice of the injection?—First, their individual physical condition.

19,279. What points did you attend to in their physical condition?—Whether they were well nourished, whether they were frail, whether they had recently recovered from illness, whether they were by nature weakly, whether there was any physical tendency; and generally, whether there were any other militating conditions, such as the existence of old disease, scrofula, or anything else.

19,280. Then you reduced or increased the dose according to these conditions?—According to the individual condition of each man.

19,281. You must have started with a standard dose; how did you ascertain this standard dose? Did you simply take what was on the bottle?—I did not. The doses written on the bottles vary, and at that time I took it tentatively. I graduated my doses. I started with the dose marked down as the standard, which was 5 c.c., in all these cases. I did not believe in initial and only inoculation: I believe in a succession of doses rapidly increased from the minimum dose.

19,282. Did you inoculate these people several times?—Yes, twice and three times.

19,283. With gradually increasing doses?—Yes.

19,284. What guided you in the number of times you inoculated the people, why did you inoculate one person once, and another person three times?—I inoculated as many as I could three times.

19,285. At what interval?—At intervals of a week or ten days.

19,286. What dose did you inoculate each time?—According to the individual I had to deal with I would give him two c.c., then three, and afterwards, five.

19,287. Why did you adopt this method in preference to M. Haffkine's method?—I adopted this method thinking of obtaining a gradual, but permanent, immunization; that was my idea.

19,288. But have you any facts to show that you can produce a gradual and permanent immunisation against plague by repeated doses?—I should have said, as perfect an immunization as possible.

19,289. What facts have you got to show that you do get a permanent immunization by this method?—Because "a perfect immunization" is a scientific fraud. In some cases—I will not say all—I found the initial dose produced a re-active fever, in the second inoculation the reaction was less.

19,290. What height of fever?—102 perhaps.

19,291. Is not that the very thing that you want to get?—Yes, for the development of an anti-toxine in the blood.

19,292. We have no evidence as to the development of the anti-toxine. Professor Haffkine told us he wanted a temperature of 102. You got that temperature, and then you inoculated people again. What facts have you got to show that three inoculations are better than one?—Because, as far as I am able to judge from the experience of others, those that were inoculated three times seemed to have a greater resistent power against plague than those who were inoculated only once.

19,293. But who else has inoculated people three times? We have not had it in evidence yet, and I should like to know who the people are who inoculated three times. It is an interesting point. Can you tell me anyone else in Bombay who has inoculated three times?—I believe Professor Haffkine has inoculated twice.

19,294. Yes, but you said three times?—There were so many inoculating in Bombay at the time, that it is difficult for me to get facts.

19,295. How can you know that three inoculations are better than one if you have no facts?—People used to come and get inoculated, and we lost sight of them after that, and there was no time to get complete results.

19,296. Why do you think it is better?—Because instead of one, you get three re-actions.

19,297. What evidence have you got to show that three reactions are better than one?—Out of all these people who were infected, I believe a small percentage of those were inoculated three times were infected within a period of two or three months.

19,298. Can you give us any statistics as to that?—It is impossible for me to give you statistics.

19,299. How many of the 2,000 people did you see again after inoculation?—With regard to the three inoculations, my object in these cases originally was to get, if possible, a view of these people again after they had been inoculated, to bring them back and get the results from them.

19,300. How many of the 2,000 people have you seen since, as a matter of fact?—I have seen numbers; I could not approximately say.

19,301. Do you know how many of them died of plague?—I could not say, off-hand, not knowing the localities where they lived in, but very few of them died as far as I could ascertain.

19,302. How many of them died of other causes besides plague?—I could not say. You could not control the population as they came and went.

19,303. I take it that you saw no evil effects from Haffkine's inoculations, and that you do not know what became of the majority of the 2,000 people you inoculated. Have you observed any after-effects from the inoculation?—Among the sequelæ of its reactive developments, idiosyncratic and other, may be mentioned neurasthenia, dizziness, and, in females, hysteria, and an asthmatic condition, varying in degree.

19,304. How long after inoculation?—A month afterwards, one particular woman tells me.

19,305. Only one woman?—No, two women. One told me she had asthma occasionally up to the age of five. After that she had never had any asthma till the age of 40. She is 40 now, and she was inoculated and got asthma and she gets asthma now. The other was a young woman of 24 years of age. There was a history of asthma in that case up to about eight years ago. She has been free from asthma for eight years, but subsequent to inoculation she developed this asthma, which continued for about four months. She was treated by several physicians, not by me alone, but by other people, and the asthma has practically passed away, but she suffers from occasional attacks of mastitis, swelling in the breasts. I cannot understand the thing myself, but there it stands. I do not put it down to that at all, I cannot trace and will not trace the connection.

19,306. Have you noticed anything else?—Aphonia, with occasional exaggeration of hysterical conditions, recurrent attacks of mastitis, articular pains, and the development of rashes, erythematous, urticarial, and one case of petechial rash.

19,307. How long after the inoculation?—Varying times; the erythematous and the urticarial within a few days of inoculation.

19,308. Were they painful?—Yes, but they passed off; it was only a matter of 24 or 48 hours.

19,309. Anything else?—And a lichenoid rash which came later on, about a week after.

19,310. Did these rashes spread from the point of inoculation?—No.

19,311. They appeared anywhere?—Anywhere.

19,312. Have you any evidence to show that these people did not suffer from these rashes before? You know well enough that when children are vaccinated every rash the child gets afterwards is put down to vaccination. Do not you think this might be a similar case? Have you any evidence to show that these rashes were due to inoculation?—They were attributed to the inoculation.

19,313. Are you satisfied yourself that they were due to inoculation?—I have seen erythema and an erysipaloid condition after inoculation, but that I put down to want of careful asepsis.

19,314. Have you seen anything else?—Isolated cases of leucoderma and leprosy have been reported I have two cases, but they are not my cases.

19,315. Then you had better not mention them. You have not observed them yourself?—No.

19,316. Anything else?—I cannot say anything else. Practically I do not believe that these results are consequent upon inoculation, or in any way influenced by inoculation.

19,317. (*The President.*) All of them; the skin eruptions and so on?—The skin eruptions may be determined.

19,318. Were the last two—leprosy and leucoderma?—No, I could not say they were.

19,319. (*Dr. Ruffer.*) You say in your précis that Haffkine's fluid is prone to putrefication: have you any facts fearing on that point?—If it stands in a bottle, it is liable to putrefaction.

19,320. It contains half per cent. of carbolic acid?—I cannot say; I am speaking of some months ago.

19,321. It putrified easily?—Yes it putrified easily. There is another curious thing in connection with this Haffkine's prophylactic fluid. We all know that perchloride of mercury is a powerful germicide, but it has no action on the toxine itself. I had used a serum bottle, and half was left. I took a strong solution of perchloride of mercury and poured it into this bottle and put this bottle inside a cage with rats, securing the bottle so that they could not by any chance drink the contents of the bottle, and over that I put a deal-wood box, and some of the rats were dead the next morning, but not with plague.

19,322. Did they drink it?—They could not drink it.

19,323. How could they get plague from the prophylactic fluid?—I did not say it was plague; it might have been toxinal poisoning.

19,324. How could they—are there any volatile substances—have you ever smelt one of Haffkine's bottles? I have frequently, but never found any smell?—I have frequently smelt them myself.

19,325. (*The President.*) What do you suggest,—carbolic acid poisoning?—No, I do not think so. Volatile toxine, I think.

19,326. (*Mr. Hewett.*) You say you were the first person to discover the mortality among rats in September 1896?—I drew the attention of the authorities to it.

19,327. Whose attention?—I mentioned the matter to Dr. Weir. He may have seen the rats himself, as he was continually down there.

19,328. Did you report it in writing to Dr. Weir?—No, I saw him personally.

19,329. (*Mr. Cumine.*) Perhaps the Commission did not understand the full significance of what you said about rats crossing the causeway. When you said that they crossed the causeway, you did not mean, I fancy, that they went from one side of the roadway to the other side, but that they ran along from one end of the causeway to the other end. Is that so?—Yes.

19,330. Are those causeways the causeways that cross the creek north of Bombay Island?—Yes.

19,331. What would be the length of the Bandra causeway?—I could not say,—some hundreds of yards.

19,332. You say you went there at night, and stopped to see if rats were passing?—I casually passed by.

19,333. You did not go specially?—I was told about it, and I casually went there.

19,334. What did you see?—I saw some rats running along.

19,335. Which way?—Towards the Bandra side.

19,336. Which way were you going?—I stood towards the Mahim side.

Dr. C. H. Freeman Underwood.

18 Feb. 1899.

19,337. Where did you stand in the roadway?—On the side of the roadway. I was in a carriage on the side of the road, not in the centre of the road.

19,338. How long did you remain there?—About three quarters of an hour.

19,339. How many rats passed?—I did not count them; several passed.

19,340. Did you follow them up to see if they went over to Bandra or were they only playing about on the causeway and did they return again to the Mahim side?—I did not follow them up, but I was told that, subsequently to this, other people had noticed the rat migration.

19,341. I want your rats please. When you had observed them for three quarters of an hour, did you go on to Bandra, or come back again?—I came back again.

19,342. You do not know whether they went right across the causeway?—I could not say.

19,343. Was there plague in Bandra at that time?—Yes, there was.

19,344. You cannot say whether these rats took plague across, or not?—I was told that they did. There was no plague up to the time of the rats going across.

19,345. Your rats?—Not my rats, but rats noticed by others.

19,346. I want to know about your rats?—Plague had been already over there.

19,347. Do you know whether rats go across every year, when there is plague and when there is no plague?—I could not tell you that. My attention was drawn to it, and I simply went there out of curiosity.

19,348. (*Dr. Ruffer.*) Did you ever see plague twice in the same person?—Yes.

19,349. Can you give us the details of the case or cases?—Yes. There is one case of a man who died in the Modikhana Hospital after three attacks.

19,350. Can you give us evidence of that case?—He was the grandson of Dr. Byramjee. He got over two attacks and succumbed to the third.

19,351. Did you see him after the two attacks?—No, I was told about it.

19,352. Who told you?—I asked Dr. Byramjee himself.

19,353. You yourself did not observe the case?—No.

19,354. Dr. Byramjee would be able to give us the details?—Yes.

19,355. Have you any other cases?—There was another case of a man by the name of Ghella, a Hindu. First of all he had axillary plague, and then four or five months afterwards he got parotid plague.

19,356. How do you know it was parotid plague?—By the symptoms, and he had high fever.

19,357. How do you know it was not mumps?—It was not mumps.

19,358. Did the man die?—No, he is alive now.

19,359. Can you find him and bring him here?—Yes, I will try and bring him here, unless he has run away to his country.

19,360. Have you any other cases?—I could not think of any just now. Some people have run away from Bombay, and the average native is very loth to come and appear before any Commission. They will tell you a good many things, but if you ask them to come and give evidence, they will not.

19,361. In the case in which you inoculated a person three times, did you find that the second inoculation produced more or less reaction?—It varied; there is no hard and fast rule.

19,362. Sometimes more and sometimes less?—Yes.

19,363. And the third inoculation?—The result was the same there, sometimes more and sometimes less.

19,364. You never inoculated a person more than three times?—Not more than three times, although some came and asked for a fourth inoculation, but I refused.

19,365. (*The President.*) I did not understand why you inoculated three times. I have no doubt you had some satisfactory reason. What was your object?—The object was this, that many of the people I inoculated complained that they were not able to rest in their houses during the period of this reaction, and they wanted a smaller dose, so that the reaction would ensue, but not so very pronounced a reaction.

19,366. Your object was to introduce by several small doses, each insufficient to produce inconvenience, a total quantity sufficient to cause immunity?—Yes, that is so.

19,367. In regard to the cases which you thought were plague cases, and where there was no glandular enlargement, had you any evidence of infection from one case of that kind to another?—No, not at that time.

19,368. Have you had any instance of infection from one person to another in the cases of glandular enlargement that you refer to?—From one to another I have.

19,369. Have you had cases where you had evidence that a patient suffering from plague with glandular enlargements conveyed that form to another patient?—I could not say definitely that it was directly from that man to another man, because people go in and out. The native customs are very peculiar. About 10 or 12 come and huddle up together in a room to see one man, and remain some hours, and then go away again to their houses.

19,370. So far, you have only had evidence that a man who has been infected in that way has had an opportunity of contracting the disease from another person similarly infected?—Yes, I have seen some cases like that in the latter years of the plague, but not in the initial cases.

19,371. In the early years that you refer to what prevalent diseases were there; were there any parexic diseases prevalent? Was tonsilitis common?—Yes, tonsilitis was present, but not to any great extent.

19,372. Did you satisfy yourself that these were not cases of acute tonsilitis? What I heard you say does not make it clear to me that they might not have been cases of acute tonsilitis?—The symptoms were so exaggerated. You do not get such exaggerated symptoms with tonsilitis.

19,373. You get a very high temperature, and prostration?—Intense prostration follows in those cases.

19,374. I do not see anything in what you have mentioned which would not be consistent with tonsilitis?—There was the general intumescence of the tissues extending right down to the clavicles.

19,375. That is the point, is it?—Yes.

19,376. You gave evidence about telluric conditions and you thought moisture of the soil might be an inducing, or an adding cause, at any rate?—A determining cause.

19,377. Is it within your knowledge that the plague bacillus thrives better in a moist surrounding than in a dry one? That is what you probably mean to say?—That is so.

19,378. What do you think is the manner in which rats infect human beings?—Rats die in a house, and perhaps, it is the exhalations from their bodies, like the exhalations from any corpse which has died of zymotic disease, and which is always prone to carry disease to others—small-pox, for instance.

19,379. By exhalation do you mean the volatile material that proceeds from a corpse?—Yes.

19,380. What volatile material proceeding from a corpse, whether that of a human being or an animal, would in itself produce plague?—If it is in a close atmosphere the possibilities are that there are exhalations from the body.

19,381. What volatile material do you refer to? Is it something different from the bacillus?—It is.

19,382. Is it possible that any other substance, excepting the plague bacillus, would cause plague?—No, it is not possible.

19,383. Then what is it you mean?—You might get intoxication.

19,384. You do not mean to say that anything but the plague bacillus, which is not volatile, would cause plague?—I do not.

19,385. With regard to Haffkine's prophylactic fluid, do you think that it is the want of "scientific potential value" which is the objection?—No, it is not an objection. It has not been determined, and I do not

advance that as an objection against the prophylactic at all.

19,386. It is a question to be investigated?—Yes.

19,387. Could you determine the potential value of an unit of this fluid?—Yes, by injecting, according to body-weight, a certain amount of the toxine or anti-toxine.

19,388. What would you do in this case? What would you test each against, and how?—By injecting rabbits or guinea pigs, and seeing the amount of resistance they may aquire, according to body-weight, against the virulent bacillus itself.

19,389. (*Dr. Ruffer.*) What do you mean by the potential value?—The resisting value in units to body-weight.

19,390. In units of what?—According to body-weight.

19,391. Body-weight of what?—For instance, you take a guinea pig and you give it a certain dose of anti-toxine. *Dr. C. H. Freeman Underwood.* 18 Feb. 1899.

19,392. Is there any anti-toxine to Haffkine's fluid?—No. I am not talking about that; I am talking about anti-toxine in general.

19,393. You say anti-toxine. I want to know whether there is an anti-toxine to Haffkine's fluid. I have not heard of it?—I have not heard of it either. The amount of resistance or immunity conferred was not determined.

19,394. On animals?—Yes; it has not been determined. That is what I meant to infer. The other matter associating anti-toxines with Haffkine's fluid was far away from my ideas altogether, knowing, as I do, that it is a solution of plague toxine in neutral mutton broth.

(Witness withdrew.)

Mr. N. Futehally called and examined. *Mr. N. Futehally.*

19,395. (*The President.*) You reside in Bandra?—Yes.

19,396. Are you a medical man?—No.

19,397. What occupation do you follow?—A merchant.

19,398. I believe you are Vice-President of the Bandra Municipality?—Yes, I was so until March last.

19,399. (*Mr. Hewett.*) Were you in charge of plague operations at Bandra at any time?—Yes.

19,400. From what date to what date were you in charge?—From October 1897 to April 1898.

19,401. During that period was plague continuously in Bandra?—There was plague in certain districts only—in two districts.

19,402. You mean to say in the villages round Bandra?—Yes, the villages included within the Municipal limits of Bandra.

19,403. When did it exist in those villages?—I first heard of a case in December.

19,404. What village was that?—In Khari village.

19,405. Did you have an outbreak in Khari then?—Yes.

19,406. How long did it last?—It lasted for 2½ months, I believe.

19,407. Did you evacuate the village?—Yes.

19,408. Did the plague spread from Khari to Bandra itself?—No, it did not.

19,409. What other village caught infection?—A village called Naupada.

19,410. How long did plague exist there?—About two months.

19,411. Did you evacuate that village?—No.

19,412. Did plague spread from Naupada to Bandra?—No.

19,413. When did you get your first case of plague in Bandra during the time you were in charge?—We had no case in Bandra then.

19,414. When was the first case in Bandra?—During the time I was in charge, there was no case in any other place except Khari and Naupada.

19,415. When did you actually give over charge?—On the 31st of March. I believe there were one or two cases in the middle of March.

19,416. Were there no cases in February?—No, not in any other part of Bandra, except the two villages of Khari and Naupada.

19,417. When did the first sporadic case take place, in March?—The first case in Bandra was in about the third week in March. There were three cases.

19,418. Do you know anything of the measures then taken in Bandra?—Yes, the measures were all taken by myself.

19,419. What measures were taken?—There were two sorts of measures, One sort had reference to the whole of Bandra generally, and the other had reference only to plague-stricken districts. With regard to Bandra town, including the plague districts, we did take some measures; that is to say, we had house-to-house visitation, examination at the station, and we issued notices that all new arrivals should report their arrival to the Municipal Officers, and we called upon the house-owners to give intimation to the Municipality of all new arrivals in their houses. Those were the general measures in all Bandra.

19,420. Whether as a result of those measures or not, plague did not touch Bandra while you were in charge?—That is so.

19,421. Since then it has broken out there?—Yes.

19,422. And has existed continuously?—Yes, it has existed continuously. Sometimes there have been great numbers, and sometimes there have only been a few attacks.

19,423. It is still there now?—Yes; it is rather bad.

19,424. Is Bandra subject to constant infection from Bombay?—Yes, it is subject to that.

19,425. When plague is bad in Bombay, are people in the habit of going to Bandra?—Yes, many people come to reside there and go daily to Bombay for business, and so are the Bandra people in the habit of going to Bombay for business.

19,426. Then the Bandra people are constantly liable to infection while doing their work in Bombay?—Yes.

19,427. Do you think that Bandra got infected by the residents of Bandra coming to Bombay and catching plague in Bombay?—The first case that occurred in Bandra was that of a woman who was resident in Bombay. She came to Bandra and brought plague with her. That was at the very first outbreak, not in my time.

19,428. I am now asking you what your opinion is as to how the place got infected after you gave over charge of operations?—I think the examination was not sufficiently strict.

19,429. The examination of what?—The examination of the people. We disbanded several of our Municipal Inspectors. The examination at the station was also discontinued, and so was the house-to-house visitation. As I have said in my précis, I believe it was through slackness of measures.

19,430. During your time were the people who went from Bandra to do their business in Bombay inspected?—Yes.

19,431. Was every individual regularly inspected?—Yes. We used to issue passes to the permanent inhabitants of Bandra who had business in Bombay. Every man had a pass, and before the pass was given to him he was examined. If he was found to be all right a pass was given to him. The pass would enable him to return to Bandra and it would say that he was a permament resident. Passes were also given to distinguished people who were not permanent residents at Bandra.

19,432. You contend that it was the abandonment of this system which led to plague getting into Bandra?—Yes.

19,433. Is that all you wish to say?—Yes.

(Witness withdrew.)

Prof. O. V. Muller.

18 Feb. 1899.

Prof. O. V. Muller called and examined.

19,434. (*The President.*) Please to inform us what you are a Professor of?—History and Political Economy at the Elphinstone College, Bombay, the Government College.

19,435. (*Mr. Cumine.*) You are a volunteer witness, are you not?—Yes, I have been a volunteer all through.

19,436. When did your experience of plague begin?—I was present as a member of the Standing Committee the day Dr. A. Yiegas announced to us that there was plague in Mandvi. As soon as the meeting was over I got on my horse and rode down to Mandvi. I have been looking on and taking part in almost every sort of operation ever since,—taking notes and photographs from the very beginning. Having a historical knowledge of plague, I tried hard to discover how the plague spread, and how it could be stopped. I studied every possible detail.

19,437. How do you think it did spread from house to house in Bombay?—When I came down to Mandvi I found the plague was existing in some six or seven houses. I noticed that the houses where the plague was were very good houses, and very often in breezy situations, and facing the docks. Many of the rooms were very excellent. I should have had no objection to living in some of the rooms myself, especially the one where the plague was so bad in the beginning—No. 45, Argyle Road. Inspector Hallams and myself disinfected that house over and over again according to the methods then in vogue, with a fire engine and phenyle and water. We cleaned it from top to bottom and whitewashed it twice. As long as there were any people left in it the plague continued to attack them. Various theories were started. The natives said it was due to the European drains that had been put down in the town. I inquired into this matter, and found that although the drains were being cleaned in Mandvi in the infected district, and the silt taken out, not a single coolie suffered from any disease whatever, although they were handing the filth supposed to contain the plague. One person started the idea that plague was due to the grain stored in godowns under each of the houses where plague occurred. I volunteered to clear out one godown at the bottom of Argyle Road, No. 45; and I was given thirty coolies to do it. I saw these coolies for many days afterwards and not one was taken ill nor was I, although at the time I was looked upon as very foolhardy. I was one of the people who showed the public that a healthy European who took reasonable care was immune. My friends in Bombay treated me as if I were a leper, and society practically cut me as it was known I was on plague duty. I noticed immediately I came down that the plague was confined to a very small district on the east of the railway, and bounded at the two ends by two railway bridges. For some days it remained there, and then it gradually spread to the other side of the railway. In every godown we opened in the morning we would find twenty or thirty dead rats. To give you an example of the abundance of dead rats, when Mr. Hankin arrived he drove down to Mandvi, and asked me for some dead rats. In five minutes I got him twenty in and around the houses in Dongri Street. He said he wanted some freshly-killed rats. I went into a house and turned over some bales. Rats ran out in all directions, and I pursued and killed some with my riding whip. They were all sick. I noticed rats on the Masjid Bunder Bridge running about as if they were drunk. You could see them lying about the streets in quantities. I have never in any other part of the town seen sick, dead, and dying rats in such quantities. Mandvi being the centre of the grain godowns, there are, perhaps, more rats than anywhere else. On hearing that this district (which contained good houses, and streets laid out at right angles) was attacked, and that rats were sick with plague, I went down to inquire from P. and O. Officers whether there was any possibility of rats coming from Hong Kong, and I was told that at Hong Kong the ships go up against the quay, so rats can both leave and go on to ships. The same applied to Bombay, but to no intervening port. From this I came to the conclusion (which I have always held, and always pointed out to foreign scientists) that plague was brought here by sea by sick rats from Hong Kong. Plague spread a week or two afterwards to Karachi—before it did to Thana or Poona. I thought my theory was confirmed by the fact, that it went by sea to Karachi much quicker than it moved by land to even neighbouring towns. Mr. Vincent, the Commissioner, has told me that he held the theory that the Sadhus from the Himalayas brought it, but personally I have always been convinced of the opinion that it came from Hong Kong in ships by sick rats. Every sailor will tell you that at every port where ships go up against the quay, rats will go on board, and also leave the ships. I should like to mention a fact which I think helped to spread plague in the beginning. Plague practically began in two houses, 45, Argyle Road, and 22, Clive Road, containing respectively 400 and 600 people; and the people fled all over the town. At first we could not get them to move. They did not care; they looked out of the windows when disinfection was going on, but afterwards they fled, and those two houses became quite empty. Then I noticed another thing. Down in the Masjid Bunder Siding Road several rich men subscribed three or four thousand rupees, and gave a huge caste dinner four days after plague broke out on the 28th of September. People were invited from all parts of the town, and were feasted in an infected house to propitiate the Deity. I urged the men rather to spend the money in white-washing these houses. The people however went and feasted there, and kept it up nearly the whole night, and then went back. Whether these people carried infection or not I was unable to ascertain.

19,438. Did you try any experiments to see whether the theory that grain spreads the plague was correct or not?—When Dr. Waters pointed out that certain grain godowns were "obviously (?)" causing plague, I got sterilised bottles; I used soda-water bottles; I went to each godown he had specially pointed out; I opened the bottles, poured the soda-water out, and took grain from where it would be most infected; I sealed the bottles, and disinfected my hands between each operation. I took the bottles to Mr. Hankin; he inoculated rats with the contents, but he failed to discover any trace of plague whatever.

19,439. Did any bad results occur to the coolies you got to assist in removing grain from the godowns?—No. I undertook to empty the godown he pointed out as particularly bad. I had 30 coolies given to me for the work; I took a careful note of them, and none of them got ill at all.

19,440. (*The President.*) How were these coolies dressed?—They were almost naked.

19,441. Were their feet covered?—No. It was very hot work. They took off what little clothes they had, all except a band.

19,442. (*Mr. Cumine.*) Will you kindly tell us whether there is any point which came to your notice, and which, so far as you know, has not been mentioned by any other witness?—I did notice that several people whose names I took down who fled from Mandvi afterwards caught the plague in other parts of the town. I know of seven people whose names I took down who left infected houses, and who afterwards died of or developed plague. With regard to rats dying before cases of plague occurred in a house I may mention I noticed that whenever dead rats were found in servants' quarters, and ladies told me of this at the Yacht Club, 10 days or a fortnight afterwards (almost with the regularity of clock work) their servants would arrive at my Servants' Plague Hospital. I have noticed too that cases have been very frequent in low-lying huts and houses, especially in houses with earthen floors; while houses with pukka floors, *i.e.*, tiles, cement, or the like remain immune. I have known fairly good houses with earthen floors which were not as immune as those with cement or stone-floors. I have also noticed that when plague comes into the neighbourhood of a village, if the whole village leave their houses and remain out until the rains there were no cases among them.

19,443. (*The President.*) It stopped plague?—Yes.

19,444. Can you mention any villages?—There is the village of Ghowari.

19,445. What is the population, large or small?—Not very large, some thousands.

19,446. Any other village?—I cannot speak with exactness except with regard to Ghowari. That I am quite certain of, because I was in charge of it. Then there is another point. I noticed that the Christian section of the village of Vadala did not suffer as much as the Hindus. They said, "We do not get plague

because we sleep on beds." I took a note of that, and I found that almost every Christian villager had a bed, whereas almost all the Hindus slept on the ground.

19,447. Why do you think that healthy Europeans are relatively immune?—I think because we wear boots and sleep on beds. Our houses are lighter, and more airy, and we keep our neighbourhoods clean.

19,448. You do not, I suppose, mean that the immunity is specially racial; if a Hindu lived under the same circumstances, he might also be relatively immune?—To a large extent. I believe it takes more plague virus to give a European plague than a native. Speaking personally, I have been scratched by plague patients and treated in various ways, I should think, that would have given a native plague.

Prof. O. V. Muller.

18 Feb. 1899.

19,449. Were any of these rats that you have referred to bacteriologically examined?—Yes, I frequently took them to the laboratories. My friends took to sending them to me in biscuit tins to have them examined, a practice I soon stopped.

19,450. I am referring to the rats at the commencement of the outbreak: were they bacteriologcally examined?—Yes, by Mr. Hankin and others.

19,451. Those for example, which seemed to you to have been the immediate cause of the importation of plague, were they examined?—Yes, rats were examined, which came from Nenaz Kairaz's house in Dongri street in Mandvi, where there had been cases, and where I killed rats for Mr. Hankin. He showed me afterwards a section of the spleen of one of the rats with a colony of microbes in it.

(Witness withdrew.)

Mr. J. K. N. Kabraji, I. C. S., called and examined.

Mr. J. K. N. Kabraji, I.C.S.

19,452. (*The President.*) You are Acting Collector at Kaira?—Yes.

19,453. You have seen plague in a large number of villages, I think?—Yes.

19,454. With regard to the first village mentioned in your précis of evidence, Igatpuri, the importation, I understand, was from Bombay?—Yes; we had five cases in January 1897, five in February, one in March, and three in April, and then, after the middle of July suspicious cases began to occur in a line of houses on the Agra Road, and the presence of plague was recognised. The infection was believed to be introduced by a Muhammadan who came from Bombay about the middle of July and died soon after.

19,455. What were the measures taken when plague showed itself there?—In the first place the sick were taken to the hospital, but the other inmates of the infected houses could not be removed easily on account of the heavy rainfall. They were just taken out for a few days while their houses were disinfected, and then they were allowed to go in again.

19,456. None of the neighbours were removed, I suppose?—No.

19,457. What was done to the houses?—The houses were disinfected and lime-washed.

19,458. Therefore you had a very imperfect evacuation, but I suppose there was complete disinfection?—Yes, there was complete disinfection.

19,459. What is the result?—The result was that there was no improvement, that is, plague had its course for two or three months and then subsided.

19,460. The result was that the plague went on increasing?—Yes.

19,461. You thought you would anticipate plague by disinfecting the houses which had not been infected?—Exactly.

19,462. What is the result of that?—The result was that plague went there just the same.

19,463. You did not succeed in your object of preventing the extension of the plague?—No.

19,464. What was the disinfection you employed?—Perchloride of mercury only.

19,465. Was that done thoroughly?—I believe it was; there were men specially looking after it.

19,466. Was it under your observation?—Major Anderson was looking after the whole arrangements.

19,467. It was not under your observation?—No; there were special men told off.

19,468. What did you afterwards do there?—At Igatpuri nothing more was done except that we got a lot of waggons from the Railway Company. That was about the time when only railway employés were living in the place with their families, all the others having gone away. A number of waggons were obtained and the people were put in them, and then all the houses were vacated.

19,469. What was the further history of the plague?—After that the plague subsided about the end of October.

19,470. By that time, therefore, there had been a comple evacuation effected, following the incomplete one?—Yes.

19,471. And the result was that plague ceased?—Yes.

19,472. Have you had any experience in Bijapur?—Yes.

19,473. The measures you employed there were of a similar nature, were they not?—In the first place there was a small outbreak at Kaladgi in February 1898. There the measures were of a similar nature, but there was complete evacuation at the same time; that was in the dry season.

19,474. The great difference is that in this instance you were able to get complete evacuation carried out, as contrasted with the former village?—Yes.

19,475. How does the history of plague here contrast with the history of plague in the former village?—In Kaladgi, after evacuation, the plague disappeared in almost no time—in two weeks. We did not disinfect every house in this case, but only the infected houses and those in the neighbourhood. The other houses in the town were cleaned out and lime-washed.

19,476. Had you experience in any other villages?—After that the real epidemic began in August last year at Ilkal. There, again, it was in the rainy season, so in the first place the people were taken to the hospitals, but after a time, I think two or three weeks after it commenced, the whole town was evacuated, and people were made to go into their fields. There was not much rainfall, so we were able to do it.

19,477. What occurred with regard to the plague?—There, too, plague subsided.

19,478. And entirely stopped?—Yes, the last case being on 15th November, 1898.

19,479. Had you any satisfactory measures for discovering cases of plague?—I employed a lot of men in the surrounding villages, in fact, in the whole taluka. It was their business simply to go round and visit two or three villages a day, and inspect new arrivals, and every house where deaths had taken place. In that way we were able to detect a number of infected villages at the very beginning.

19,480. Do you think that very important?—I think so, because it happened in some of the cases that we detected the first or the second case of plague and the village was turned out, and after that the mortality was very little.

19,481. You have had other instances in which complete evacuation had been effected, I think?—Yes.

19,482. Was the result in them the same?—We have always noticed that plague went down after evacuation.

19,483. Where the evacuation was only partial it did not go down?—No.

19,484. What was the result when you adopted disinfection only?—I cannot say that disinfection did any harm, but I consider it was simply thrown away—all the money was thrown away on disinfection. We got just the same result without disinfection. I simply compare Igatpuri with Ilkal. At Igatpuri we disinfected every house, and in some cases we disinfected streets in advance of plague before they got infected. All the same, plague went there.

Mr. J. K. N. Kabraji, I.C.S.

18 Feb. 1899.

19,485. Into these very houses?—Yes. At Ilkal we did not do any such thing.

19,486. How soon after disinfection were the houses re-occupied at Igatpuri?—They were allowed to go in within three or four days. It sometimes took three or four days and sometimes a week. At Ilkal the people were turned out but only the infected houses were disinfected, and then the people were allowed to go in again, and the results have been the same with very little cost.

19,487. Can you tell me the result?—At Ilkal plague subsided two months after, practically, and it did so also at Igatpuri. In spite of disinfection it took two months before plague was got under there. At Igatpuri the people were allowed to go in after that time and also at Ilkal, and there has been nothing since at Ilkal.

19,488. In both cases it stopped?—Yes.

19,489. Can you contrast disinfection with complete evacuation?—There was no evacuation at Igatpuri for some time, but at Ilkal we started evacuation within a month of plague appearing there.

19,490. How soon after evacuation did plague disappear?—At Ilkal plague disappeared in three weeks after evacuation; at Igatpuri it went on for a long time in spite of disinfection.

19,491. Will you tell us what you mean by a "long time"; was it months or weeks only?—At Igatpuri we had the first recognised case on the 2nd August, and the last case on the 2nd November.

19,492. It went on for three months?—Yes.

19,493. Have you the details?—I have a statement for Ilkal also which shows that at Ilkal it subsided in somewhat less time. I put in those statements.

19,494. How soon after complete evacuation did it subside at Ilkal?—Evacuation at Ilkal commenced in the beginning of October and was completed about the 3rd week of October. By about the 20th of October the whole town was out, and completely evacuated. The last case occurred on the 15th November.

19,495. When did the majority of cases occur after evacuation?—The highest mortality was just about the middle of October.

19,496. How many days after evacuation is that?—I should think evacuation was just near finishing by that time.

19,497. How many cases were there after complete evacuation?—After that cases went down from 15 to eight, four, five, and so on, and on the 5th and 6th November there were no cases.

19,498. What do you think is the reason that complete evacuation is so efficacious?—I consider the chief reason is that people go into the fields, where they get plenty of light and air.

19,499. Why do you think so?—Because that is the only difference that I can see between huts in the field and the houses in the town.

19,500. Generally speaking, the houses with which you have been dealing were defective in those respects?—Native houses are always badly ventilated.

19,501. And always badly lit, do I understand?—Yes.

19,502. Were they overcrowded?—In many cases they were overcrowded.

19,503. Generally speaking, or not?—Yes, generally speaking, they were overcrowded for villages of that stamp, but not to the same extent as in Bombay.

19,504. Had you any experience of preventive inoculation?—I have not had much experience of preventive inoculation. At Ilkal we inoculated people after the town had been evacuated, and before they were allowed to go into their houses. A few families were allowed to stay in the town after being inoculated; they were not turned out.

19,505. Did any harm result?—No. There were a few cases. I think 12 deaths occurred among the inoculated people, but they occurred two or three days after inoculation, so that they were, perhaps, already infected.

19,506. These 12 cases might have carried on the infection in the village which they were allowe to remain in?—Yes, they might.

19,507. There is a certain amount of danger there?—Yes.

19,508. You have formed some opinion as to the time which elapses between the first importation of a plague case and the actual occurrence of an outbreak?—Yes.

19,509. Will you give us the facts?—The first time it attracted my notice was at Igatpuri, where I ascertained that some Muhammadans came from Bombay in the middle of July. The first death among them was on the 21st July. Then it was nearly 12 days before any further deaths took place in that locality.

19,510. You always received early information? Your machinery was adequate?—Yes; but we did not receive information about these arrivals from Bombay, because we had stopped medical inspection just about that time.

19,511. You found that out afterwards?—Yes.

19,512. Have you any other case?—I observed it more closely at Ilkal, where a man, who was suspected to have brought the infection, died on the 31st of July, and the first death which took place in that house afterwards was on the 20th August. On the 31st July a Marwari Banniah came from Hubli, and died at Ilkal. That death passed unnoticed. Then the man he had been living with died on the 20th August, and his wife on the next day. That started the plague at Ilkal.

19,513. That was the second case?—Yes. After that I have had some other instances. As one illustration I may say that in this way I detected what, I believe, was the first indigenous case of plague ot Bobleshwar, a large village in the Bijápur táluka. It is situate between two infected villages. I told the people they were in imminent danger, and advised them to live in their fields as a precautionary measure. They emphatically said they had had no communication with either of the infected villages. They, however, assented to my suggestion to thoroughly ventilate their houses. This they set to do, but while I was inspecting the progress made and also visiting the houses where deaths had taken place within the preceding four weeks, I came upon a house where that very morning (17th December) a man had died in a certain house and I was informed that his wife had died in the same house on 23rd November. After a deal of cross-examination it was brought out that the woman had been to a funeral at Kakhindki, one of the infected villages in question. Two days after her return she had died. Regarding this, therefore, as an imported case, and allowing three weeks for full incubation, I came to the conclusion that the husband must have died of plague. I also ascertained that three days before his death he had been seen going about. I therefore segregated that family as also those of the brother and the sister of the deceased—occupying adjoining houses. In another house, at the back of the first one, the wife of the occupant was absent, and was said "to be living at her father's house for some time." She was visited there and found to be feverish. She, as well as her parents, were segregated. On the third day following she died, apparently of pneumonic plague. Two of the sons of the first case, as well as his brother, also developed plague (as pronounced by a Hospital Assistant) in quick succession. By this time all the people of the village voluntarily cleared out in two days. After this there was no fresh case or death for whole week; and there had been only five cases and three deaths up to that time. Unfortunately, it so happened that I had allowed a woman, who was very near confinement, to stay in her house with her husband and children, as I thought there was no immediate risk of that locality being infected. Almost all the members of that family, however, got plague after a few days, and were the means of spreading the disease among others living in the fields. Barring this mishap, I consider that Bobleshwar is a notable instance of the success attending immediate evacuation if the first case of plague is spotted. It also shows that it is not enough to evacuate the portion of the village which is immediately infected, as other localities eventually get infected. This happened, although I had caused the roofs of all the houses in the infected block to be completely removed within three days. I understand, also, that dead rats were subsequently found in different localities, even after the people had quitted the houses.

19,514. Is the interval, elapsing between the first imported case and the first local case, the same in dry weather as it is in damp weather?—I think it is shorter in damp weather. I have given some instances and can give others to show that nearly three to four weeks elapse before an imported case, if left alone, causes indigenous plague in a hitherto uninfected locality. This fact helps to detect the first signs of plague. The period may be shorter in damp weather. This interval of time should be always borne in mind in calculating the effect of the admission of people from infected areas into another place, and raises important considerations as to the safety of the present surveillance and detention system. I have further observed that cases of plague are sometimes developed in the fields 10 to 20 days after evacuation, although the people have not mingled with infected persons.

19,515. What do you say with regard to disinfection?—Except at Ilkal, disinfection with perchoride of mercury was abandoned, and the infected houses were only ventilated, generally by removing the roofs altogether. This is easy to do, as in that part of the country the houses are only one-storeyed with flat mud roofs, which it costs little to renew. The very poor persons can be compensated. From my experience I think disinfection, considering its cost and other drawbacks, has not been proved to achieve the purpose for which it is undertaken. It is not proved that immediately a house is disinfected after an infected family is removed from it, another healthy family can safely go and live in it, much less the original family. Disinfection in advance, too, has failed, as I have said above. On the other hand, the very fact that a properly made Plague Hospital does not require to be disinfected every time a case dies, and that the medical and other attendants can safely live in it, shows that disinfection must be a superfluity in other infected houses, provided other conditions are the same, and I fail to see what they can be but the ventilation—the free admission of daylight and fresh air. With this view we insist that when people evacuate a village and go into the fields they should not create the same unhealthy conditions again by making air-tight and badly-lighted huts as they are prone to do, but should leave plenty of passage for light and air. If disinfection is authoritatively given up or condemned, it will not only result in a saving of nearly half of the cost of operations in rural areas, but will remove a highly fruitful source of irritation to the people, so that still another inducement to conceal will be taken away. It has been observed that by far the largest majority of plague cases, if not all, occur when the sleeping-rooms are badly or insufficiently ventilated or lighted. Even if there are windows or ventilators, the people are in the habit of closing them at night. This may sufficiently account for the occurrence of plague among the well-to-do classes. On the other hand, people living in open spaces, even in filthy surroundings, escape infection. I think ventilation should have precedence even over the cleaning up of houses and streets. It is advisable not to stir up the refuse of ages until some time had elapsed after the evacuation of a house or locality. This would also minimise the occasions for people to re-enter evacuated villages. Ventilation should immediately follow evacuation, but the cleaning may stand over for a month or so, and be carried out a few days before it is proposed to let the people in again.

19,516. (*Mr. Cumine.*) Have you had experience of two epidemics in one district?—No, not actual experience. I only know that at Igatpuri there has been a recrudescence lately.

19,517. From what place did the case come which infected the Bijapur district?—There were practically two epidemics in the Bijapur district, one at Kaladgi, which was stopped, and then, after some months, it broke out at Ilkal.

19,518. From what places did the two cases come which set up these two epidemics?—At Kaladgi, it was supposed that some people had come from Sholapur, which was badly infected at that time, and at Ilkal it was thought the man had come directly from Hubli, but they said he had also come from Bombay with a pass some days before. He came first from Bombay to Hubli and stayed there, and then came on to Ilkal and died there. Hubli was badly infected then.

19,519. Did you have instances of people coming from Bombay and developing plague in villages in the Bijapur district and not infecting the villages?—I have not come across any.

(Witness withdrew.)

(Adjourned till Monday next.)

At The Secretariat, Bombay.

FIFTY-FIRST DAY.

Monday, 20th February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.
Prof. A. E. WRIGHT, M.D. | Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. B. N. Darabsett.

20 Feb. 1899.

Mr. BARAMJEE NAOROSJI DARABSETT called and examined.

9,520. (*The President.*) I believe you are a practitioner of medicine in Bombay?—Yes.

9,521. What are your medical qualifications?—I am a graduate of the Grant Medical College, and I have practised here for the last 39 years.

9,522. We chiefly want to have some information in regard to one special case which I believe you have had under your care, a man who we are told has had three attacks of plague. Would you be good enough to give us a narrative of the case of this man?—Yes. The notes I have here have been put down from memory. Munchershaw was a young Parsee, aged 26, residing in Modi Street.

9,523. In what district is that?—In the Fort. He was of fair complexion and sanguine temperament, strong, healthy, and hale. He was of fair stature. The first attack he had was in Poona. He had been there for a change for about 10 days. About the 10th of February he had shivering and an attack of fever, followed by swelling in the right inguinal gland. He was then treated with brandy, quinine, diaphoretics, and belladona plaster, the ordinary treatment for fever. He got well in about 15 days.

9,524. Had he been inoculated?—No.

9,525. That was the first attack?—Yes. He got over that. The second attack occurred about the middle of April 1897. The attack came on with shivering and high fever. After a time there was a rusty-coloured sputum, with crepitations in the lungs. He was treated similarly internally, and was frequently sponged with carbolic acid lotion.

9,526. On which side did the enlarged glands occur?—On the left side. He had an enlargement on the left side in the second attack. In the first attack it was on the right side. The inguinal glands on the left-hand side were enlarged, and he was treated with an inhalation of carbolic acid with steam, and frequent external spongings with carbolic lotion. This time he recovered in 20 days. On neither occasion was there any suppuration of the inguinal gland. The third attack was on the 25th of January 1898. It commenced with high fever and shivering, followed by hæmorrhage from the nose and lungs. No glands in the groin were enlarged, but enlargement of the gland in the neck and chest appeared the day previous to death. No inguinal glands were affected on the third occasion, but he again had pneumonia and hæmoptysis.

9,527. Were the glands within the thorax affected, the mediastinal glands?—Yes.

9,528. How did you find that out?—He complained of a very severe pain in the chest. We were obliged to inject morphia hypodermically.

9,529. How do you know that the glands within the chest were enlarged?—Because of the chain of glands extending down into the mediastinum.

9,530. Part of the neck was enlarged?—Probably the glands could not be felt at first. The man died on the 1st of February after an illness of about six or seven days.

9,531. Was there any *post mortem* examination?—Certainly not; he was a Parsee.

9,532. What was the man's occupation?—He was employed as a clerk in a photographic office.

9,533. Can you tell us to what extent he was exposed to plague before any of these attacks?—He was exposed to plague; he was living in a plague house.

9,534. On which of these occasions?—On all three occasions he was in the same house.

9,535. He came from Poona, did he not?—The first time he was in Poona. The very next day after the attack he returned to Bombay, to Bazar Gate Street, and he was treated in Modi Street for the last two attacks.

9,536. With regard to the first attack, he was at Poona and came to Bombay. Did he become ill in Poona or in Bombay?—The fever commenced in Poona.

9,537. With regard to that attack, what was the exposure to plague—the first time?—The first time, I should think, he exposed himself in Poona.

9,538. What was the exposure in the second attack. How was he exposed to your knowledge?—Plague cases occurred in the house he lived in.

9,539. And the third attack?—The same. Previous to his dying there had been two deaths from plague in the same house.

9,540. Had not the house been disinfected before he became ill?—Very perfunctorily—just whitewashing with lime. At that time strong disinfectants were not used. Latterly, however, they have been used more freely.

(Witness withdrew.)

Mr. Champaklal Thakurdas.

Mr. CHAMPAKLAL THAKURDAS called and examined.

9,541. (*The President.*) What is your occupation?—I am in Government service. I am an Inspector in the Bombay Custom House.

9,542. (*Dr. Ruffer.*) When did you first have plague?—On the 11th of October 1896.

9,543. Can you describe the symptoms you had at that time?—That day, being Sunday, in the evening I went to visit a friend of mine. At that time I was living in Kandawdi near Girgaum. My relative was living near Kalbadevi. On reaching half way I got some pain in the left groin. I did not care for the pain, and I at once proceeded to the house of my relative. I sat there for half-an-hour, but in the meantime I began to shiver from the effects of cold. I informed my relative about it, and he predicted that this would be followed by high fever.

19,544. Did a swelling appear in the groin?—It appeared afterwards.

19,545. When?—An hour or so after I got the fever.

19,546. How long did the swelling last?—It lasted for four days.

19,547. Did it suppurate, did matter come out of the bubo?—It was not operated upon. It subsided by the mere outward application of a plaster.

19,548. What was the highest fever you had?—My temperature went up to 105°.

19,549. Had you ever had an attack like that before?—No, not before that.

19,550. Are you a married man?—Yes.

19,551. Did you have any pain anywhere else at that time?—Only in the left groin.

19,552. You had no pain in the testicle?—No.

19,553. Or anywhere else in that region?—Nowhere else.

19,554. Did you have any pain in the abdomen?—At that time I had no pain anywhere else.

19,555. The swelling went down in five days?—Yes.

19,556. How long did the fever last?—Five days. For two days my temperature was 102°, and on the third day it was 102°. Then it began to subside, and on the fifth day I was all right.

19,557. Was your appetite good?—I did not take food all the time.

19,558. Did you want to eat, or not?—On the first day I did not want to eat, but on the second day I thought I was feeling hungry.

19,559. What was your tongue like, do you know?—I was very thirsty.

19,560. Do you know whether your eyes were red?—My eyes were red.

19,561. How do you know?—They told me so.

19,562. You got quite well of that?—Completely.

19,563. When was the second attack?—On the 29th of March 1897.

19,564. Where?—That day I attended office, and while going home in the evening I felt rather uneasy, and on the road I felt pain in the very same part.

19,565. Had the gland remained enlarged between the first and the second attack? Was the swelling you had the first time still to be felt when you had the second attack?—Although there was no pain there was a small gland inside the skin which could be felt, but it did not cause any pain.

19,566. How long did the second attack last?—Very nearly three months.

19,567. How did it begin, with fever?—First of all I felt some pain in the same place. That pain afterwards subsided when I got fever.

19,568. How long did the swelling last in the groin?—In the second attack it was cut open.

19,569. When was it cut open?—After 15 days.

19,570. Why was it cut open?—Because it was ripe.

19,571. There was matter in it?—Yes, there was matter in it.

19,572. Did you have a swelling anywhere else?—When the suppuration was going on I felt some electrical current passing from that part to the middle of my thigh, where I have another cut. On the next day there was another swelling.

19,573. What was that other cut in the middle of the thigh; why did you have another cut there?—They operated upon it in the hospital.

19,574. Afterwards?—Yes. On the next day there appeared some swelling on that part. That was also poulticed. After eight days that was also operated upon.

19,575. And pus came out?—Yes, and pus came out.

19,576. Did you have any swellings anywhere else?—The same swelling appeared in the groin.

19,577. When was that?—That was some 10 or 12 days after the operation.

19,578. How long did that swelling last?—That swelling lasted until I recovered.

19,579. How long was that?—I think some portion of it remains now.

19,580. How long after the first, second, and third swellings had been opened did they remain open?—The first healed in 15 days, and the second also took 15 days.

19,581. What about the third?—The third was not opened.

19,582. It healed up without being opened?—Yes.

19,583. Did you have headache the first time you had plague?—The first time I had no headache.

19,584. Did you have headache the second time?—No.

19,585. Did you have any delirium the first time?—No, I had no delirium the first time, but the second time I had.

19,586. How long did it last?—It lasted for nearly two days.

19,587. Were you seen by a medical man each time?—On both times I was seen by a medical man.

19,588. Who was the medical men who saw you the first time?—Mr. V. S. Divan.

19,589. Did he think you had plague?—Afterwards he took it to be a plague case.

19,590. He did not at first take it to be a plague case?—No.

19,591. The second time he had no doubt about its being a plague case?—No. He removed me to the Plague Hospital.

19,592. Did any of your relatives get plague either on the first or second occasion?—No.

19,593. Was there any plague where you lived?—No.

19,594. Did you feel very weak after the second illness?—Yes, I was very weak.

19,595. How long did the weakness last?—For three months.

19,596. Were your eyes injected—red—the second time?—I do not remember.

Mr. Champaklal Thakurdas.

20 Feb. 1899.

(Witness withdrew.)

Mr. NARAYAN MULJEE called and examined.

Mr. Narayan Muljee.

(*Dr. Godinho acted as interpreter.*)

19,597. (*The President.*) What was the date of your first attack of plague?—September 1896.

19,598. What glands were then affected?—The glands in the right groin.

19,599. How long did that attack last?—A month and a quarter.

19,600. By whom were you treated?—I was treated by Dr. Ismail Jan Mahomed.

19,601. Where?—I first went to him, and then he called upon me.

19,602. Where is your house?—Nos. 2, 4, and 6, Falkand Road, C. Ward, opposite Dr. Ismail Jan Mahomed's dispensary.

19,603. When was the second attack?—A month and a half after I recovered from the first attack I got the second attack.

19,604. That would be about November?—Yes.

19,605. Which glands were then affected?—The cervical gland on the left side.

19,606. How long were you ill?—About a fortnight.

19,607. Were you treated in the same house?—I did not take any medicine from the doctor; I was treated at home.

19,608. When was the third attack?—In the month of August 1897. First my brother was attacked and then my father was attacked.

19,609. What glands were affected?—The glands in the right axilla. I was operated upon for that.

19,610. How long did the third attack last?—A month and a half, six weeks.

19,611. On which occasion were the glands opened?—Only once; on the third occasion.

Mr. Narayan Muljee.

20 Feb. 1899.

19,612. Do you know if you had been specially exposed to plague infection?—I cannot give any cause for the first infection. I took the second infection from my tenants.

19,613. What tenants? How long had they been ill before you became ill?—I do not remember how long before.

19,614. Was it before you were ill?—They were ill before I was ill.

19,615. Was it a week or a month before?—Within 15 days.

19,616. Were you living in the same house?—Yes.

19,617. How did you get the third attack?—First, my brother was attacked. He died. Next, my father was attacked, and he died. Then I was attacked; and after me four others were attacked.

(*Dr. Godinho.*) I remember about those four cases.

19,618. (*The President.*) Had you been inoculated?—No.

19,619. I suppose there was no bacteriological examination?—(*Dr. Godinho.*) Nothing was done in 1896.

19,620. (*Dr. Ruffer.*) Did you have other symptoms besides enlarged glands, did you have headache?—First I had severe pains in the head, and next, I had nausea and vomiting.

19,621. Did you have fever?—Yes. Those symptoms were immediately followed by fever.

19,622. How long did the fever last on the first occasion?—About 16 or 17 days.

19,623. (*The President.*) How do you know that?—I was unconscious for seven days, and afterwards I became all right.

19,624. You said the fever lasted 16 or 17 days; how do you know?—I did not move from home, that is how I know it.

19,625. (*Dr. Ruffer.*) Did you have any fever on the second occasion?—The second attack of fever was mild.

19,626. Did you have headache then?—I had a chill.

19,627. Any vomiting?—No.

19,628. Did you have fever on the third occasion?—I went to the funeral ceremony of my brother, and afterwards I went to the tank and had a bath. I felt chilly there and I came home.

(*Dr. Ruffer.*) Is there anything to see under your axilla? Have you still got the scar? (*The Commissioner here examined the axilla of the witness.*) I see the scar is about half-an-inch long on the outer border of the *pectoralis major* muscle: it is not in the axilla.

(Witness withdrew.)

Mr. G. Monteath, I.C.S.

Mr. G. Monteath, I.C.S., called and examined.

19,629. (*The President.*) You are in the Indian Civil Service, and are Assistant Collector at Thana?—Yes.

19,630. (*Mr. Cumine.*) In what districts have you had experience of plague, and for what periods in each?—In Satara for six or seven months, and in Thana since June last.

19,631. In your précis of evidence you mentioned the town of Tasgaon. At first, was your evacuation confined to the infected houses, and those immediately surrounding them?—Yes, it was.

19,632. Did you find that that stopped the spread of plague in the town?—Not at once.

19,633. What did you go on to evacuate?—The whole of the infected quarters, by pets and blocks.

19,634. Did that stop the spread of plague in the town?—It did, in a little less than three months.

19,635. Why did you have finally to resort to complete evacuation of the whole town?—The town was never completely evacuated.

19,636. When there were fewest people in the town, about how many were there left?—Under 1,000.

19,637. As regards the infected villages, did you have some instances where, having got the first one or two cases, partial evacuation was successful in preventing the spread of plague in the village?—Yes, I remember two cases.

19,638. But in the majority of cases did it fail?—In the majority of cases the plague was not found out immediately on the first case occurring, and so partial evacuation failed.

19,639. In order to make evacuation produce the maximum of good, with what other measures must it be supplemented?—First, I think you must separate the sick, and also the inhabitants of the same houses, from the healthy population.

19,640. That would be one measure; what is the other?—And disinfect the houses themselves.

19,641. And prevent communication with the infected houses?—Yes, as far as possible.

19,642. If in a district there are a large number of villages infected, is it practicable for the Collector and his staff to effectively carry out, in the case of each village, the measure of evacuation with the two or three complementary measures that you have mentioned?—I do not think so, judging from the Satara district, unless all the village officers are to be depended on.

19,643. Have you anything to tell us, in connection with monkeys, as to the way in which the poison hangs about evacuated houses?—I give the instance for what it is worth. When the village was evacuated, large numbers of monkeys used to enter the houses by the gaps made in the roofs, seeking what they could steal I noticed, on riding into the village on one occasion, a monkey drop dead from a tree above the chavdi. On inquiry I learned that 10 or 12 had died similarly—some in the houses. Coming again to the village a few days later, I was told that five or six more had died.

19,644. Did you have any of them bacteriologically examined?—No.

19,645. You mention, in your précis of evidence, Parli Fort as a good instance of the way in which rats helped to spread the disease. Do you mean spread the disease from house to house within a village?—Yes, from house to house.

19,646. How do you know it was rats that were spreading it from house to house?—I went up there and found out for myself.

19,647. How did you satisfy yourself that it was rats?—I saw one or two, and all the people agreed that rats were dying in nearly every house in the Fort. It is a very confined place, of course.

19,648. I ask how you knew it was rats that were carrying it from house to house?—I think it was by rats, but I did not prove it.

19,649. Have you any notes to show how long after the arrival of an imported case, which infects the village, the first indigenous attack occurs?—I have no notes; but I remember that, in Vasadage, it seemed to take about 14 days.

19,650. Have you noticed whether rats are, or are not, always attacked between the imported case and the first indigenous case?—Yes, I think that is almost always so, according to what I have seen.

19,651. Would the imported case appear to infect the local person directly, or would it appear to infect the rats first, and then the rats infect the local person?—It seemed to me that it infected the rats indirectly, and then they spread the disease from house to house. I do not know, but that is what it seemed to me.

19,652. Do you think you quite understand my point? We have been told by one witness that there always appear to be attacks amongst rats between the imported case and the first indigenous case, as though the imported case were unable to infect the local people directly, but had to do it through the medium of rats. Have you noticed that at all?—I have noticed it, yes.

19,653. That rats always died between the imported case and the first local case? Can you say confidently that you have noticed that?—I have noticed that they almost always so die.

19,654. Would you read us what you say in your précis about Wasind?—Wasind, taluka Shahapur, was infected about August 20th, 1898. Fortunately the village was

discovered to be infected before the first indigenous case occurred, from the fact that rats had begun to die in several houses. A good many persons left the village of their own accord, and on the occurrence of the first case the whole of the inhabitants of the infected area (the bazar) were made to go and live in the fields. Two or three cases occurred among the railway hands, whose families lived in the bazar. The disease died out almost at once. In November a solitary case, apparently of plague, occurred at Wasind; the same measures were put in force, and there were no more cases. One case was reported on December 9th, but I do not believe it was plague, since it was neither preceded nor followed by other cases, nor by the discovery of dead rats.

19,655. Who said that the case on December the 9th was plague?—It was reported to me by the Mamlatdar as plague.

19,656. Since one case in November, and one case in December, appear to have occurred, would you say that the outbreak of August the 20th had died out, or that it appeared to be smouldering?—I think it had died out, there have been no more cases since.

19,657. Is there any plague in Wasind now?—No.

19,658. Has the death rate of Wasind been abnormally high lately?—No.

19,659. Is there any plague in Kalyan at present?—Yes, there is.

19,660. Has the segregation of contacts been abandoned in Kalyan?—Yes.

19,661. What has been the effect of that?—What happened immediately afterwards was that the number of cases a day were nearly doubled.

19,662. And then?—And then in about a fortnight they decreased again.

19,663. Do you leave any of the patients in their houses in Kalyan, if so, which?—Cases occurring among persons who pay Rs. 20 and more income tax are allowed to be segregated in their own houses, one or two members of the family remaining to attend the sick person, and the rest being directed to remove either to another house or out of the town.

19,664. Do you disinfect daily these rooms in which the patients are?—No.

19,665. You find that bad results have arisen from leaving the patients in their houses?—Directly or indirectly, altogether. The rest of the people want to follow their example, and it is rather difficult to deal with them.

19,666. Do you find that many other people have been infected by these patients?—No, I cannot say so.

19,667. Do you find that the people left to nurse them get plague a good deal from them?—I do not think so, anymore than they would if they were turned out.

19,668. Have you had any experience of inoculation?—No, none at all.

19,669. Has any instance come to your notice of plague having appeared in a village which was infected last year, and which has had, so far as you can make out, no fresh infection this year? Has, in fact, any instance of a real recrudescence, from the original germ, come to your notice?—Which was not re-infected this year?

19,670. Quite so?—I do not remember any.

Mr. G. Monteath, I.C.S.

20 Feb. 1899.

19,671. Did you allow these patients in Kalyan that you left in their rooms to be put on a bed, or did you allow them to lie on the floor?—They mostly had beds.

19,672. If they have not, do you put them on a bed?—No.

19,673. (*Mr. Hewett.*) Have you tried the kiln system of disinfection at all?—Dr. Dadima has tried it in Kalyan.

19,674. Is it expensive?—No, not as it is done.

19,675. Do you think, supposing that disinfection with perchloride of mercury is equally effective, that it is preferable to the kiln systems that are substituted for it?—I do not know, but I have seen no results from the kiln system.

19,676. Supposing they were equally effective, which would you prefer?—I think the kiln system would be better and cheaper probably.

19,677. You think it would be cheaper. Do you think that it would involve less interference with the people than disinfection by means of perchloride of mercury?—No, I do not think it would.

19,678. Do you think that it would interfere more with them?—Yes, I do, somewhat more.

19,679. You tried burning down huts once or twice, did you not?—Yes, I did twice.

19,680. Were they isolated huts?—They were.

19,681. People would not like that to be done on a large scale?—They would not.

19,682. Did you find it effective in thec ases where you burnt them down?—I did in those two instances.

19,683. Had you a single case in each hut?—Yes, a single case.

19,684. (*The President.*) What do you think, in your experience, is the most effective method of dealing with an epidemic of plague?—The most effective seems to be to turn all the people out, or as many of them as possible, into the fields.

19,685. Evacuation?—Yes.

19,686. What is the largest town or village in which you carried out that method?—Kalyan, I suppose; it is practically evacuated.

19,687. What is its population?—The normal population would be about 13,000.

19,688. Within what time did you effect the evacuation of the town, how long did it take?—It took about three months, gradually.

19,689. You did not try to do it all at once?—No.

19,690. What is the kind of house in the district you are now talking about?—In the villages most of them live in very poor huts—chappars.

19,691. How many chambers in each hut?—Sometimes two, sometimes three; they are only separated by chappar.

19,692. What outside openings have they got besides the door—have they any windows?—No, no windows.

19,693. Only a door?—Yes, only a door, or doors.

(Witness withdrew.)

Lieut.-Colonel A. W. F. Street, I.M.S., called and examined.

Lt.-Col. A.W.F. Street, I.M.S.

19,694. (*The President.*) You are in the Indian Medical Service and Sanitary Commissioner for the Presidency of Bombay and Sind?—Yes.

19,695. What are your medical qualifications?—M.R.C.S.E., and L.R.C.P.Lond.

19,696. (*Mr. Hewett.*) Can you give us the total mortality from plague, and the rate per mille per annum, first in Bombay, and secondly, in other parts of the Bombay Presidency and Sind, from 1896 to the present time, also the mortality from all causes at the same time and the rate per mille; also the mortality from cholera and the rate per mille; and also the mortality in all diseases classified as fever?—I put in a statement which gives the figures asked for.*

19,697. Have you any Assistant Surgeons employed under you in the Sanitary Department in the Bombay Presidency?—There is only one Assistant Surgeon in the Department, but he has no sanitary duties.

19,698. How many Deputy Sanitary Commissioners have you got?—Five.

19,699. Does a Civil Surgeon in the Bombay Presidency and Sind have any authority as regards sanitary matters?—Not any real authority; in his own town he interests himself to a certain extent.

19,700. Has he any responsibilty as regards th sanitation of the Municipalities in his district?—No, do not think so, except in places where there are dispensaries, and in his headquarter station.

19,701. Nor as regards the sanitation of rural areas in his district?—No, none.

* *See* App. No. LVII. in this Volume.

Lt.-Col. A.W.F. Street, I.M.S.

20 Feb. 1899.

19,702. The whole responsibility as regards the rural areas at all events rests with the peripatetic officers; the Deputy Sanitary Commissioners, and you?—Yes.

19,703. Are you Inspector-General of Vaccination, as well as Sanitary Commissioner?—Yes, vaccination is one of the duties of the Sanitary Commissioners.

19,704. Have you any establishment as Sanitary Commissioner, distinct from the establishment which you have as Inspector-General of Vaccination?—Only clerks.

19,705. What is your vaccination establishment?—Inspectors and vaccinators. The Inspectors of Vaccination are Inspectors of Sanitation as well.

19,706. What is the number of vaccinators employed under you?—388.

19,707. And of Inspectors of Vaccination?—One Superintendent of Vaccination, Bombay, one Superintendent of Vaccination, Karachi, one Assistant Superintendent, Bombay, 31 Inspectors of Sanitation and Vaccination.

19,708. You say these Inspectors are employed on sanitary matters?—To a certain extent.

19,709. Have they any sanitary qualifications?—No, no qualifications; no pass qualifications. They pick up a certain amount of knowledge when with the Deputies on tour.

19,710. They have not been trained in hygiene?—No.

19,711. What is the rate of their pay?—Rs. 55, 75, 100, and including travelling allowances Rs. 75, 100, 130.

19,712. Are any of them Assistant Surgeons?—No, except the one in Bombay, who has no sanitary duties, and he gets Rs. 380 pay and allowance.

19,713. Would it in your opinion be a good plan to substitute for your present Inspectors of Vaccination, Assistant Surgeons who have been trained in hygiene?—Do you mean in order to benefit vaccination?

19,714. I mean in order to benefit sanitation?—Yes, of course, but I do not know whether vaccination would be benefited.

19,715. Why do you think vaccination would not benefit?—Because I like the men who have gone through the mill and risen from vaccinators.

19,716. On what ground?—Because they know all the ins and outs of the work.

19,717. Do you think that an Assistant Surgeon could learn the ins and outs of vaccination?—I do not think he could as well, not unless he went through the mill himself.

19,718. Has the Inspector been through the mill?—Yes.

19,719. Could not the Assistant Surgeon acquire the necessary knowledge?—Yes. I do not doubt, if you got very good men, he might.

19,720. Can you suggest any means by which you can obtain earlier notification of cases of plague other than the improvement of the class of your subordinates?—Of course we have the village officers.

19,721. Do you think that the responsibility of the village officers is one which can ever be properly enforced? Can they know what is plague and what is not?—That is so.

19,722. Can you suggest any other means of improving the system of notification?—You cannot supervise every village with a fully qualified man in that way.

19,723. My idea was that a qualified Assistant Surgeon might, while on inspection work, be able to help you to some extent if he had to look round and inspect the village and examine its condition from a sanitary point of view; might he not assist you as regards the recognition of plague?—He might, but the villages are very numerous, and he would have a large number of villages. My vaccinators have done a little in that way. They have always been told, if they come across anything of that kind, to report it.

19,724. Is their utility in this respect not rather affected by the fact that they could not tell a case of plague?—Yes; but if the village officers knew that plague was in the village, and the vaccinator went there, they would not let him work, and would tell him that there was plague, and, therefore, he could not work, and then if plague was being concealed, its existence would come out.

19,725. You think that you could, under present arrangements, find out the existence of plague in places where it exists to a considerable extent?—Yes.

19,726. I was thinking more of trying to find the first cases?—That would be a very big business owing to the extent of the country and the number of villages.

19,727. I do not quite understand why an Assistant Surgeon, who had been properly trained, should not be able to check the ordinary vaccinators in their work?—I do not see why he should not, if we got good men; but I prefer a man who has gone through it all from being a vaccinator.

19,728. Have you any authority as Sanitary Commissioner over the city of Bombay?—No, except as regards vaccination, and to a certain extent, over the Health Officers of the Port.

19,729. (*Dr. Ruffer.*) Who appoints the Deputy Sanitary Commissioners?—Government appoints them, but there are generally candidates for the post, and the Sanitary Commissioner would choose and recommend a man to the Government.

19,730. Are they chosen from men who have got special qualifications in sanitary affairs?—I do not know. I suppose a man would be preferred if he had.

19,731. As a rule they are not?—I cannot say absolutely.

19,732. Have you got a voice in their choice?—Yes, I think so. If I knew a man I wanted, I should ask for him; and if a man wanted an appointment he would write to me and say he wanted to come to the Sanitary Department, and I would pick out the best man, and ask for him if there is a vacancy.

19,733. You have five Deputy Sanitary Commissioners?—Yes.

19,734. How many of the Deputy Sanitary Commissioners have any qualification in Sanitary Science?—I know one has; I do not think any of the others have.

19,735. What qualification has he got?—D.P.H.

19,736. Of Cambridge?—I think so; I am not sure.

19,737. Have you any authority over Civil Surgeons?—No, none.

19,738. How large is the District the Deputy Sanitary Commissioner has to visit?—I have only just taken up the office of Sanitary Commissioner. I have been a Deputy for years.

19,739. How large is your district?—It is as big as Scotland.

19,740. How often do you visit each village?—I could not visit each village.

19,741. You have never visited each village?—No. I have got five Collectorates, and they are divided into talukas, and it is as much as I can do to visit half my talukas in one year. I ought to have only half the district, if I had to visit each taluka. The average number of villages in one taluka is 154; the numbers range from 49 to 394.

19,742. The large majority of the villages are not visited from year to year by a Sanitary Commissioner, or a Deputy Sanitary Commissioner, or anyone holding a Sanitary qualification?—A very very small proportion. Of course the Inspectors visit a fair amount.

19,743. I believe there is a Provincial Sanitary Board?—Yes.

19,744. How often does that meet?—I cannot say; I have just taken over the duties.

19,745. How long have you been Sanitary Commissioner?—About a month.

19,746. Has it met during that time?—No.

19,747. Can you tell me how many formal meetings they have had in the last three years, and whether minutes were taken?—During the monsoon, once a week, or oftener if there is anything urgent. During the fair season, perhaps, once a month. No minutes are kept as the Board has no initiative, and is, therefore, only a consultative body to consider plans and proposals transmitted to it by Government and others.

19,748. Have you any disinfecting apparatus in Bombay apart from the plague work?—No.

19,749. None whatever?—No, not that I know of.

19,750. Have you any disinfecting arrangements at all for other diseases besides plague?—No, I do not think so. When the plague began, I do not think there was

a single disinfecting machine in Bombay, so far as I remember.

19,751. What are the number of villages the vaccinator goes through in the course of the year?—I generally like to give them about 80.

19,752. How often does he get into these 80 villages, once or twice?—Every one once, and the big ones twice, as many as he can of the big ones.

19,753. (*Mr. Cumine.*) Did you tell us how many Sanitary Inspectors you had? Take the district of Ahmednagar; how many are there in that district?—One to each Collectorate; I have got two in Satara.

19,754. In one Collectorate, how many hundred villages would there be?—A very very large number, 403 to 2,824.

19,755. (*Prof. Wright.*) How many members are there on the Sanitary Board?—Two members; the Sanitary Commissioner and the Sanitary Engineer.

19,756. Have you any other work beyond inspecting vaccination?—Sanitary work and vaccination.

19,757. What does the Sanitary work consist of, reporting on accumulations of dirt?—Inspecting the Municipal towns. The Sanitary Commissioner confines himself to the Municipal towns. The Deputies go everywhere.

19,758. What does the Sanitary Commissioner do?—You inspect a town and see what they have and what they want, what can be improved; and then you put it on paper in the form of a report.

19,759. Supposing there is an epidemic of cholera, do you take any practical measures, or do you simply write a report?—In most large towns, where you do anything, there would be a Municipality most likely, and they are put into motion. There would be a Civil Surgeon most likely.

19,760. Has the Sanitary Department anything to do with fighting cholera in a cholera epidemic, for instance?—It does what it can. You cannot do much except in the large towns. For the country we try to improve sanitary matters by a better water supply and that sort of thing. That is the only way to get over cholera in the districts.

19,761. There is a good deal of inspecting; but is there any practical action taken?—It is difficult to get any action taken. It is generally through want of funds.

19,762. Do you think the inspection does any good, short of taking practical steps as the result of that inspection?—Yes, it does a certain amount of good. It keeps Municipalities up to their work, and you may get some improvements even if there is no money to do it with, and then when the time comes you have got it down on record what is to be done. You can advise the Municipality what they ought to do, and when they get money they may spend a certain amount in the necessary improvements; and when they get more they may turn their hands to the other things.

19,763. I see the expenditure of the State upon the Sanitary Department: I do not see the return that accrues to the State, except in the case of vaccination?—If they give us money we are prepared to do more.

19,764. (*The President.*) What are the chief duties of the Deputy Sanitary Commissioner?—Vaccination and sanitation.

19,765. How much of the time is occupied in vaccination work?—The seven months that he can get out he travels in the districts and inspects. He does vaccination and sanitation work at the same time.

19,766. The chief work is vaccination?—Yes, we have money for it and we do it.

19,767. It is a sort of incident to his work that he does sanitary work?—There are certain sanitary duties to do when he is on tour. Every village I go to I see the water supply and that kind of thing; and in every Municipality I make a thorough inspection,

19,768. Do you go into the houses to see what the actual conditions in the houses are, or take any cognisance of overcrowding or ventilation?—No; not, as a rule, in the country, but we do in the towns, when necessary. We know what the conditions are.

19,769. Any cognisance into the conditions of milk supply?—I am speaking of the country now.

19,770. Any part of your district—country or town?—In the towns we do, but to a very limited extent, and only, as a rule, in the case of European supplies.

19,771. I thought you said the amount of vaccination work was so large that it practically occupies the whole time?—You have to go a certain number of miles to a village, and when you are there you can do both. If I had to go 20 miles in one direction to see sanitation, then 20 miles in another to see vaccination, it would take a lot of time, but I can do both in the same village.

19,772. What do you mean by both? You mean with regard to large questions like those of water supply?—Yes, water supply, the surface cleanliness, and surface drainage. Those are the things we chiefly want in villages, good water supplies and good wells.

19,773. I did not quite gather how long it took you, when you were Deputy, to go round your own district?—Two years. I could hardly do it in two years.

19,774. Did you visit every village of a fair size in two years?—No.

19,775. How long would that take you?—I could not do it.

19,776. Ten or 20 years?—Yes.

19,777. With regard to the Inspectors, who have smaller areas to deal with, what are they termed—what is their official title?—Inspectors of Sanitation and Vaccination.

19,778. Do they merely inspect the vaccination, or do they themselves vaccinate?—They inspect.

19,779. In regard to the work of vaccination, how often can they go through and inspect the district which they have to deal with?—They go through every part of it once a year or more.

19,780. It requires very nearly a year to inspect the vaccination of that area?—Yes.

19,781. Then there cannot be very much time left for examining the details of the sanitary conditions, I presume?—No; except, as I say, you can combine the work. I mean if you are in one place, your vaccination does not take you the whole day. You can do your vaccination work, and then you can do your sanitation work in the village. The distances are so great that the work must be combined.

19,782. (*Mr. Hewett.*) You have not mentioned anything with regard to vital statistics. Is it not a part of the duties of the Sanitary Commissioner and Deputy Sanitary Commissioner to supervise the collection of vital statistics?—We register all the births and deaths.

19,783. Do not you go round and check the correctness of the registers?—Yes.

19,784. Is not that one of the most important duties of your inspecting staff?—Yes, it is one.

19,785. Then you are not entirely occupied in vaccination?—Oh no, that is another part of it. They do that in the villages they go to: they examine, in fact, all the registers, the sanitary registers, the vaccination registers, and the cholera registers.

19,786. (*Mr. Cumine.*) You were asked by Professor Wright what share the Sanitary Department take in fighting an epidemic. Do they take any share at all in the actual fighting of it when it breaks out?—It depends; if it is a big Municipality they do.

(Witness withdrew.)

Lieutenant H. P. Keelan, I.S.C., called and examined.

19,787. (*The President.*) I believe you are a member of the Indian Staff Corps?—Yes.

19,788. And you were engaged in plague work in Hubli?—Yes.

19,789. (*Mr. Hewett.*) Could you state the dates between which you were employed at Hubli?—From the 25th of December 1897 to the 10th of October 1898. From the 10th of October 1898 to the 11th of November 1898 I was in Dharwar, a few miles from Hubli.

19,790. What is the normal population of Hubli?—About 55,000.

19,791. At the time you went there in December was there any plague?—There had been some cases in the railway chawls before we arrived there; and for about,

Lieut. H. P. Keelan, I.S.C.

20 Feb. 1899.

I think, 25 days at a time, we used to find one solitary case now and again. There was not plague really for the first month after I arrived there.

19,792. What duties were you employed on first?—I was first employed in the railway station, disinfecting passengers.

19,793. When did plague actually begin to attract your attention in the town of Hubli?—About April, I think.

19,794. What measures did you take when it broke out in the town in April?—We had the ward system going on the whole time before that.

19,795. That is a system by which you hoped to discover cases, is it not?—Yes.

19,796. Please describe the system?—The city was divided into ten sub-divisions, and each sub-division was divided into wards. Each ward had a certain number of Ward Supervisors, and there were Ward Superintendents over the Ward Supervisors.

19,797. How many houses had each Ward Supervisor to look after?—From about 90 to 120.

19,798. How many Supervisors had the Ward Superintendents to look after?—About 10. They were not aequal. There were 10 in some, and 11 in others, and so on.

19,799. Did this arrangement give accurate and immediate reports of all cases of sickness?—As far as we could make out it did at the beginning, when the cases were few.

19,800. You think that you found the first case that occurred in Hubli?—I was not there when the first case occurred.

19,801. Do you think you found the first case that occurred when plague began for the second time in April?—That I cannot tell. I am doubtful about that myself.

19,802. When did the system cease to work satisfactorily?—When the panic set in.

19,803. When did the panic take place?—About May, when the cases began to increase. During the rains, generally, it went up. In May, June, and July the panic kept on increasing.

19,804. When you heard of a case of plague, did you remove the sick person out of his house?—Yes.

19,805. What did you do with the healthy persons residing in the house?—We segregated them.

19,806. How many camps had you?—Two camps.

19,807. How many people were in these camps at any one time?—We have had as many as 2,500. It was a bad time of the year.

19,808. What was the maximum you had in your camps at any one time?—Over 2,000. I was not running it myself.

19,809. Who was running it?—Dr. Leumann.

19,810. Did many of the people leave the town?—Yes.

19,811. In what months did they leave the town?—I think it was in July and August.

19,812. Had you a system of issuing passes before they left the town?—Yes.

19,813. When was that introduced?—From the time of my arrival there they had a system of passes.

19,814. Did you give passes to people who went by road as well as by rail?—Yes; but there was no check upon that at all.

19,815. Would any individual who came to you and asked for a pass be entitled to get it?—At first he was, if we knew if he lived in a fairly healthy locality where there had been no plague.

19,816. When did the system change?—The system was changed when inoculation came in.

19,817. Do you remember when that was?—I could not tell you exactly when that was.

19,818. After inoculation came in you only gave the certificates to persons who had been inoculated?—Yes.

19,819. Was it necessary that they should have been inoculated more than once in order to obtain a certificate?—As a rule the people were twice inoculated.

19,820. Were you then responsible for giving the certificates to the twice inoculated who went away by road?—Yes.

19,821. Do you think that the people continued to leave by road after this rule was introduced with regard to inoculation?—Yes.

19,822. Do you consider that as many of the inoculated left as of the uninoculated persons?—No. We found that out by asking our Ward Supervisors to send in lists of the number of persons inoculated, and the number of persons uninoculated every week.

19,823. Then you think that more uninoculated persons left than inoculated?—Yes.

19,824. In spite of the fact of your system of passes?—Yes.

19,825. Then the system of passes was practically useless?—Yes, as far as the road was concerned.

19,826. Were there persons who had been twice inoculated, and who were allowed to remain in their houses when plague occurred in them?—Yes.

19,827. What did you do to the houses in those cases?—We had them disinfected and put back those people who were taken out for the time being.

19,828. Leaving the patient in the house?—No; the patient was taken away to hospital.

19,829. Did you collect any figures to show that in these cases the inhabitants of the houses were not attacked by plague?—I collected particulars of about 200 cases where the uninoculated were attacked, and the inoculated were left in the town and got off.

19,830. Were the figures which were attached to Captain Leumann's Report,*—the 69 cases in the appendix—collected by you?—Yes, the majority of them; more than that, I collected about 200 cases.

19,831. Did you personally verify in each instance the names of the persons said to be inoculated?—Yes.

19,832. And the names of the persons said to have died from plague?—Yes. I went to the houses and asked them all to show their passes.

19,833. What I mean to say is this: supposing you went to house No. 744, did you test whether the five individuals who were said to have been inoculated and to have escaped plague were then present, and whether they had been actually inoculated?—Yes. I took away all the passes, and asked them their names separately.

19,834. Did the deaths from plague come to your notice in the ordinary business of plague administration?—Yes.

19,835. Then are you responsible for the accuracy of the Appendix of Captain Leumann's Report?—Some of the cases were got by him, but the majority were got by me; I do not know whether he has got mine or his.

19,836. Did you find that cases of plague were notified mainly before or after death?—Mainly after death.

19,837. When you had a case notified to you after death, how did you determine whether it was the body of an inoculated or uninoculated person?—We went to the house and simply asked if the person had been inoculated.

19,838. Supposing the residents said that he had not been inoculated, did you accept the statement?—The person's name was sent in, and Dr. Leumann proved whether the person had been inoculated or not in his records.

19,839. Did the records contain the the place of residence of each person inoculated as well as his name?—Yes.

19,840. Was Dr. Cardoz employed in the identification of bodies?—No.

19,841. Did you take the original census of Hubli?—No.

19,842. By whom was it taken?—It was taken before my time.

19,843. Were you responsible for ascertaining through the Superintendents how many persons arrived in Hubli and departed from Hubli each week?—Yes.

19,844. Did you then deduct from your assumed population the number of deaths and the number of persons who had departed, and add to it the number of persons who were reported to have arrived?—Yes.

* *Vide* App. No. XV, in the first Volume of the Commission's Proceedings.

They were not exactly accurate always. There was generally a discrepancy of one or two in each ward.

19,845. Do you think that the result was approximately accurate?—Yes.

19,846. Assuming that the original census figure was right?—Yes.

19,847. Do you rember any date from which a difference was made in recording the number of deaths of plague among the once inoculated?—No. I always put down whether they had been once inoculated or not. The people in the houses generally told me.

19,848. Do you think that cases of deaths from plague among the inoculated were actually recorded as having occurred amongst the uninoculated?—Yes, I think so; there may have been a few left out. I know for certain that some had gone away and died, because they were brought in sometimes, and we got accounts. But the inoculated almost all stopped in Hubli.

19,849. The assumed population of Hubli at the beginning was 58,000, and by the 13th September 1898 it had fallen to 38,408. Of that 38,408 what number do you think had been inoculted?—I should have said by the figures I had then that there were about 3,000 or 4,000 who had not been inoculated.

19,850. Do you continue to hold that opinion?—Yes.

19,851. You do not think there were more than that?—No.

19,852. When you were at Dharwar what privileges were given to the inoculated?—They were given passes. They were allowed to stay in the houses, just the same as in Hubli.

19,853. Notwithstanding permission to stay in their houses, did not a large proportion of the population of Dharwar run away?—They evacuated their houses and lived outside.

19,854. Do you mean that they left the town of Dharwar and that you did not know where they had gone to?—They would be in big camps round Dharwar.

19,855. About how many people were there in those big camps?—I should think in one of the camps there were 400 or 500 people.

19,856. Could you estimate the total population which you think might have been in those camps?—There were huts and camps all over the place, all round Dharwar.

19,857. Do you think there were 10,000 altogether?—Quite.

19,858. Do you think there were more?—I could not tell you that, but I should think there were quite 10,000 people.

19,859. How many were there left in Dharwar town?—I do not remember. I know that a great many went away by train when the first case or two occurred; they went through Hubli by train when there were no restrictions whatever on Dharwar.

19,860. Did a considerable number of inoculated people leave Dharwar?—Yes, they did.

19,861. Did more uninoculated people leave Dharwar than inoculated?—We never tested that.

19,862. You did not test it as you did in Hubli?—No.

19,863. Do you think that more uninoculated people went?—I think about an equal proportion of each. They simply went out into their huts outside, and used to come in from there to be inoculated.

19,864. Do you know how the uninoculated people got back into their houses in Dharwar?—I think they had huts outside and used to come in and sleep at night.

19,865. But when they went away you used to lock their houses up, did not you?—No, we did not.

19,866. You were not there when the houses were locked?—I was there in October and November.

19,867. The houses were locked when we were there?—They locked the houses themselves. There was a rule that the people must be twice inoculated before they were allowed to return to their houses.

19,868. How could you prevent them going back if they themselves had locked their houses?—The Ward Supervisor would go round every morning, and if he learned that a family had come back who were uninoculated, those people would either have to go to the health camp or else be turned out again.

19,869. How long was that rule in force?—From the beginning of plague there.

19,870. (*Dr. Ruffer.*) I do not quite understand how your census was taken. Did the Ward Supervisor go round all the houses each week and ascertain the number of people?—Yes; every Sunday morning he went round. That is the day we thought most people would be in because all the cotton mills and workshops were closed. A lot of people in the railway workshops lived in the town.

19,871. How did you ascertain the number of people? Did you get all the people out in the street and see them?—That was the order given.

19,872. Did the Supervisor do it?—I cannot say that, but it has been done in some cases. I used to go round some of the wards during the week.

19,873. Did you find that the previous statements of the Ward Supervisor were correct when you yourself went with him, or did you find any marked discrepancy?—There was never any marked discrepancy.

19,874. Supposing an inoculated person died, was the house treated in the same manner as when a non-inoculated person had died?—So far as disinfection was concerned it was treated in the same way, but otherwise the people were taken out of the houses and put back again.

19,875. The inoculated people?—Yes.

19,876. What was done with the uninoculated people in the same house?—They were taken to the segregation camp.

19,877. (*Mr. Cumine.*) Does this Appendix* take in all the houses in which inoculated and uninoculated people lived together, and in which plague cases occurred?—No, there are only 69 cases there, I think.

19,878. On what principle were those particular houses selected?—I was told to get good cases, houses where several had been inoculated, and one or two had not been inoculated. There were a lot of houses where perhaps one person had not been inoculated and the others had, and those I should call good cases, where only one of the uninoculated got the disease. I could not go round to see every case when they got heavy.

19,879. I want to know why you went to these particular houses?—Because they came in my beat. I used to take a division one day, and in other cases I would ask the Superintendant to report to me, and I would go and verify it.

19,880. Did you ever see the register kept of inoculated persons?—No, it was kept in the Plague Hospital.

19,881. You do not know whether the names and addresses of each individual were got down fully?—The Pet was put down.

19,882. Have you ever seen the inoculation process going on at the busiest time?—Yes.

19,883. How many people were done in one minute?—I should think about 2.

19,884. When you were making inquiries from house to house as to attacks among the inoculated and the uninoculated, and certain people came forward with inoculation certificates, saying that they were inoculated people who had escaped, did you make any endeavour to make certain as regards each person producing such a certificate that he was really the person named in the certificate?—My method was to take all passes away from the people. A certain number of people showed me their passes, and I asked each one what his or her name was. Then if the name given corresponded with the name on the certificate I gave it back.

19,885. Did you make any endeavour to find out whether the person was giving the correct name or a false name?—I do not see how they could find out what names were on the passes.

19,886. But did you make any endeavour?—No, the inoculation certificates were all written in English.

19,887. Supposing a person has a certificate and dies, and his brother annexes the pass, would he not know that his brother's name was on the pass?—Yes, he would. There is no way of ascertaining that.

19,888. (*Prof. Wright.*) What were the inducements offered to people to get inoculated?—The inducements were, that in case of plague occurring in the house, the inoculated persons would not be segregated or sent

* Vide App. No. XV. in the first volume.

Lieut. H. P. Keelan, I.S.C.
20 Feb. 1899.

to the health camp. Also, in case of an area being turned out, inoculated persons would not be sent to either of those camps. They could also travel anywhere in the district with a pass, whereas people who were uninoculated would not be given a pass.

19,889. Do you think that the people felt that there was any pressure being applied?—At first they did.

19,890. Do you think, therefore, that uninoculated people would have tried to escape observation? For instance, would they have gone out by the back door when the census was taken and try to hide themselves?—Yes, they did.

19,891. How do you explain the enormous mortality of 65 per cent. there was in certain weeks among the uninoculated? Do you think that represents the actual mortality among them, or do you think there were more uninoculated people than was stated in the returns?—There may have been a few more uninoculated, but I do not think there were many more. I think that this census which was sent in was really correct for each division to within 50 or 100.

19,892. You think there was actually that enormous mortality among the uninoculated in those particular weeks?—Yes.

19,893. I undertand that the total mortality among the uninoculated was 14 per cent., while some weeks it rose to 65 per cent.?—Yes.

19,894. Can you account for that in any way?—No, I cannot. The only thing is, that plague got into a bad quarter where the people were not inoculated. It got into the Muhammadan quarter and carried them off right and left. The plague seemed to go from north to south, it started near the railway workshops, and went straight down to the south of the town. When it got to the congested quarters it took off more people.

19,895. You think the excessive mortality during those particular weeks may be accounted for by the fact that plague had spread into the densely populated and uninoculated quarters?—Yes, I think so. I cannot put any other construction upon it.

19,896. Do you know, as a matter of fact, of the existence of any such uninoculated areas in Hubli?—Yes, there were one or two uninoculated areas where people were most loth to come up for inoculation, but they gradually came up afterwards. I do not know what time the plague was there.

19,897. Can you suggest any means of finding out whether an excess of mortality occurred in those particular areas in those particular weeks?—The returns would show. I suppose they have got the returns in Hubli showing the number of deaths in each of those wards.

19,898. (*Dr. Ruffer.*) Did I understand you to say that the population of Hubli was 55,000?—When I arrived there I think the population, according to the last census, was 52,000, and I estimated there were about 3,000 more people since the census had been taken.

19,899. (*Mr. Cumine.*) With regard to the principle on which you selected those 69 houses, you said you took them because they were good cases?—Yes.

19,900. Do you mean good cases as showing the protective power of inoculation?—Yes. If I went to a house and saw that none of the people had been inoculated, and a person had died, I would not call that a good case. I had lots of cases where there was one person inoculated and four or five uninoculated in the same house, and an uninoculated person died there. I did not think so much of that case as I did where 10 persons were inoculated and the 11th was uninoculated, and the uninoculated person died.

19,901. Did you enter in this statement any cases where, there being both inoculated and uninoculated in a house, it was an inoculated person who was attacked, and all the uninoculated persons escaped?—All the time I was there I got three cases where every person in the house had been inoculated and one of them got the plague.

19,902. That is not my question. Have you got in this statement any house in which, there being both inoculated and uninoculated people, all the uninoculated escaped, and one or more of the inoculated people were attacked?—No.

19,903. Can you say that no such houses existed?—None came to my notice.

19,904. It is not the case that you rejected such cases and entered only those favourable to inoculation?—No.

19,905. When you had prepared this statement, who compared the names in it with the names in the inoculated register in the possession of the Inoculating Officer?—Dr. Leumann, I presume.

19,906. You did not?—I did not. Is imply sent in the cases with the number of the pass and the date on which the man was inoculated. They were sent to Dr. Leumann, and he selected them out of about 200 cases which I sent.

19,907. When a man did not produce a pass, did you assume he was uninoculated?—Yes.

19,908. Did you ever find cases where it was declared that a man had been inoculated, but where he had no pass to produce?—Very seldom. The people looked after the passes far too well.

19,909. When you did find such a case, did you return it as inoculated or uninoculated?—Uninoculated, if I did not see any pass. If they did not show me a pass I presumed they had not been inoculated, and I sent them either to the health camp or the segregation camp.

19,910. You had no extract from the inoculation register which is in the possession of the Inoculating Officer?—No.

19,911. You cannot tell us whether the entry in the inoculation register was so full as to enable you to identify the person entered?—No.

19,912. You cannot tell us whether it was a full entry or not, whether it gave the man's name and stated that he lived in such and such a house in such and such a street?—I cannot tell you that.

(Witness withdrew.)

Dr. W. Venis.

Dr. W. Venis called and examined.

19,913. (*The President.*) You are Divisional Health Officer of Bombay?—Yes.

19,914. Of what division?—No. 3.

19,915. What wards?—Byculla, Mazagaon, Tarwadi, Tardeo, Kamatipura, and 1st and 2nd Nagpada Sections.

19,916. (*Prof. Wright.*) You have had experience of corpse inspection in Poona?—Yes.

19,917. Is corpse inspection done in the houses after death?—Yes.

19,918. Was it never done at the cemeteries or burning ghats?—No.

19,919. Do you think it is better to do it in the house than at the cemetery?—Yes, because if it turns out to be a case of plague you know where the case occurred, as a rule.

19,920. Do the people object more to your doing it in the houses?—No, they do not object much in Poona.

19,921. Supposing the body was already dressed and prepared for burial when you arrived, was there any objection to allowing you to examine it?—In my own experience there were only objections on two, or, perhaps, three occasions.

19,922. Were you able to detect any other cases of plague besides the bubonic form by means of this corpse inspection?—In some cases we had a suspicion of pneumonic plague, but, of course, we could not be absolutely certain.

19,923. Do you think the system of discovering plague by corpse inspection is the best which can be adopted?—I think it is the best practicable means. It would be better if you could have all the cases notified and see them during life, but that is quite impossible.

19,924. Do you think that system would be applicable to a town like Bombay?—I should think probably not from what I have seen of Bombay.

19,925. What difference is there?—They are a different class of people; they are not so likely to be amenable to argument.

19,926. What do your duties consist of at present? Do you find out plague cases?—I have nothing to do with plague.

19,927. You are employed in the Health Department?—Yes.

19,928. Your only experience of plague is at Poona?—Yes.

19,929. Does your evidence bear upon anything else but evacuation and corpse inspection?—Simply corpse inspection and notification of illness. I was in charge of two of the camps at one time.

19,930. (*Dr. Ruffer.*) Were you ever able to examine the sick at Poona before they were removed from the house?—Yes.

19,931. How did you induce the people to let you see them?—There was no inducement required; they used to come and report the sick and the medical men used to report them.

19,932. Had they any objection to your seeing women?—No.

19,933. Did the Musalmans object at all?—Very rarely.

19,934. In Poona, did you always examine corpses in the houses or sometimes in the cemetery?—Never at the cemetery. The body could not be removed from the house until we saw it.

19,935. Do you think they removed the body from one house to another?—I think they did occasionally from one room to another, but we used to disinfect the whole house, and it did not matter.

19,936. Did you disinfect the people?—They were sent to the segregation camp and detained there for ten days. On arrival in camp they were given a bath, and their clothes were disinfected. This routine was observed while plague prevailed in epidemic form. Later on close segregation was abolished and the people simply slept in the camp at night and went about their work during the day, but the disinfection of the persons and clothing of contacts continued as before.

19,937. Did they have mercurial baths?—Yes, perchloride of mercury. I forget the exact strength.

19,938. Did you ever get a case of mercurial poisoning?—Never.

19,939. Did you ever see a case of mercurial poisoning among the disinfectors?—Never.

(Witness withdrew.)

Major T. E. Dyson, I.M.S., called and examined.

19,940. (*The President.*) Where did you acquire your experience of plague?—I was first of all in Bulsar in the early months of 1897; afterwards, at the latter end of the year and the early part of 1898 I was in Surat.

19,941. What do you think is the manner in which plague is spread?—I think it is spread by human agency from place to place. In Bulsar plague was undoubtedly introduced from Bombay, and I think in Surat also, but I cannot speak positively about that. There are many people in Bulsar who have dealings in Bombay, and have houses in Bombay; they fled from Bombay in thousands, and the first cases occurred among them.

19,942. Having been imported, how did it spread, do you think?—I think it spread by human agency again and by rats into different parts of the town.

19,943. Have you any distinct evidence of its being spread by rats?—I have no distinct evidence that the rats died of plague; they were never examined, but there was an epidemic among rats as there was among human beings. There is a village close to Bulsar, where the first evidence of the existence of plague, preliminary to the outbreak among the people, was the death of rats in a particular quarter, while the people were not affected until afterwards. They promptly turned out of their houses and went into the fields to live, and developed plague a week afterwards among themselves.

19,944. Could they not have acquired plague by being infected by persons suffering plague?—They might have got it from Bulsar itself.

19,945. From human subjects?—Yes.

19,946. You have no more distinct evidence of the conveyance by rats?—No, not of the actual conveyance, but simply that in Bulsar itself large numbers of dead rats were found in quarters before plague appeared among the people, and also concurrently with cases among human beings.

19,947. When you got an imported case what steps did you take?—Unfortunately no steps were taken at all. The imported cases ran through their course to death or recovery before they were found out in the first instance. When they were detected they were removed to hospital, and at that time nothing was done to the rest of the inhabitants of the place.

19,948. Have you any opinion as to the length of time which elapses between the entrance of infection and the outbreak of an epidemic?—As far as I can judge in Bulsar it must have been six weeks, it may have been eight weeks. Of course, it is very difficult to know exactly. We have to take the time from the time when the cases were detected, or at any rate when there was an appreciable increase in the mortality. That occurred in Bulsar about the end of January.

19,949. But in the meantime, of course, plague cases may have been occurring?—Yes.

19,950. With regard to the treatment of an infected area, what did you find was the most successful measure?—I tried in Bulsar first of all cleaning and disinfection with lime. Afterwards, through want of labour, we tried the perchloride of mercury solution as being simpler and easier of application. In the two areas I have quoted it seemed to have distinctly good effects.

19,951. I believe you did something more than mere disinfection?—Yes, that was later. One particular quarter of the town was evacuated.

19,952. What measure do you regard as successful in dealing with an infected area?—I think evacuation and disinfection.

19,953. Have you had any experience of evacuation without disinfection by chemical disinfectants?—Without any disinfection at all? In some of the villages there was very little done more than opening up the houses, removing the tiles, and letting a free percolation of air through them.

19,954. And after evacuation?—I do not know any instance in which the people were allowed to enter their houses again within a month, very often two or three months, and after the plague had ceased among them out in their sheds.

19,955. What followed from their return?—They had no more plague.

19,956. That is to say without chemical disinfection, and simply by opening up the houses you found those houses did not again infect people when they returned?—That is so, after a lengthened stay away from the houses.

19,957. Have you any experience of disinfection after very brief evacuation—say a week or a few days?—In Bulsar, in two of the quarters there, I allowed the people to re-occupy their houses within a fortnight, I think.

19,958. No briefer period?—No.

19,959. That was in the case of houses which had been disinfected by chemical agency, I suppose?—Yes.

19,960. What was the result?—They had no more plague after the fortnight.

19,961. What is your opinion as to the infectiveness of plague in its different forms?—The most common form—the bubonic form—does not seem to be very infectious. We had numerous instances of Hospital Assistants, and particularly children having to be taken in with their sick mothers, and they never were affected by plague afterwards.

19,962. What is your experience with regard to corpse bearers?—From some statistics I collected in Surat

Major T. E. Dyson, I.M.S.

20 Feb. 1899.

there does not seem to be any special danger attached to corpse bearing.

19,963. How many people were you dealing with?—I was dealing with nearly 400. In only two or three instances was there any suspicion that the plague might have been contracted in that way.

9,964. You think that the bubonic form is not very infectious?—Yes.

19,965. How do you account for the occurrence of a considerable number of cases of bubonic plague in one house?—I should say they contract the infection from the original source. The house is infected and the germs enter through the abrasions of the skin.

19,966. What is your experience with regard to the infectiveness of pneumonic plague?—I have had no experience at all of the pneumonic form.

19,967. You saw no cases?—I could not say whether the cases I have seen were primary pneumonia or secondary pneumonia following on plague.

19,968. You have no clear cases?—I have no clear evidence at all.

19,969. Have you any experience of curative sera?—None whatever.

19,970. Have you any experience of Haffkine's prophylactic fluid?—Yes, I had some experience, but it was not entirely my own. All the figures I have obtained were got from the Assistant-Surgeon in Bulsar.

19,971. They are not your own?—No, they are obtained from him.

19,972. Can you give us those figures?—Yes. In an isolated corner of the town there were 1,018 people inoculated, and I have the figures of a portion of those people, some Muhammadans who had plague very badly. There were 539 of these Muhammadan weavers, of whom 490 were inoculated, and of the remaining 49, 20 were not inoculated because they had had plague in the previous year, three were not inoculated because they were sick with plague at the time, and 17 were not inoculated because they were children under two years of age; nine persons escaped inoculation of whom we have no record. After the inoculation of these 490 persons 64 cases of plague occurred with 23 deaths.

19,973. Do you know the intervals which elapsed between inoculation and the occurrence of plague?—I can only give the weeks and the number of cases.

19,974. Do you know how many deaths occurred among them?—No, I do not.

During	1st	week	after	inoculation	there were	12 cases.
,,	2nd	,,	,,	,,	12	,,
,,	3rd	,,	,,	,,	15	,,
,,	4th	,,	,,	,,	11	,,
,,	5th	,,	,,	,,	8	,,
,,	6th	,,	,,	,,	3	,,
,,	7th	,,	,,	,,	3	,,
					64	

19,975. Were these inoculated persons left in the village or town?—They were left in their houses with their sick.

19,976. Previously to inoculation, had many cases of plague occurred there?—In an adjoining quarter there were some fishermen living, and there were about 20 or 30 cases among them.

19,977. Not in this actual quarter?—Not in this actual quarter.

19,978. Was any measure taken in the adjoining quarter?—The whole of the fisher people were inoculated as well as these Muhammadans, and some Muhammadans in the adjoining quarter, but I only have reliable figures about these particular Muhammadans which I have mentioned. Among the Muhammadans inoculated in the adjoining quarter who had not plague at the time no epidemic ever broke out.

19,979. (*Dr. Ruffer.*) How many times did you inoculate the Muhammadans?—Only once.

19,980. Did they all re-act?—I do not think they did. I did not do it, and I did not actually see it done.

19,981. Do you know the actual number of plague cases which occurred among those who had had plague before?—I know of one instance. A boy who had had plague the previous year got plague again the second year.

19,982. Then you stated you had 17 children under two years of age; do you know whether any of them got plague?—I am afraid I cannot say among whom the cases in the people left out occurred, whether they occurred among the people who had had plague the year before or among the children or those who escaped inoculation.

19,983. But you know of one case of a boy getting plague twice?—Yes.

19,984. (*Prof. Wright.*) Did you see any of these cases which occurred among the inoculated?—Yes.

19,985. You thought they were much milder than the cases among the others, did you not?—The mortality was considerably different. Some of the cases were very severe, but I think, on the whole, the epidemic was milder; the mortality was only half what it had been the previous year.

19,986. You state, in your précis, that other people refused to be inoculated?—In the rest of the town.

19,987. Because there was still plague?—Yes, among those who had been inoculated.

19,988. Were the symptoms in the inoculated persons so severe as to frighten the people?—No; I think the simple reason was that the inoculated people still continued to have plague among them, although they had been inoculated, and the other people did not see at the time there was any benefit to be derived from inoculation.

19,989. Do you think the inoculated were the same class of people as in the other quarters of the town?—There is another quarter containing exactly the same class of people, and they had plague afterwards. Their mortality was very much the same as in the previous year, over 70 per cent. They were exactly the same class, Muhammadan weavers, only they lived in a different part of the town.

19,990. 70 per cent. was the percentage of mortality among those attacked?—Yes.

19,991. Do you know what the percentage of attacks was among them?—Their numbers were altogether 492, and they had 65 cases with 47 deaths.

19,992. (*Dr. Ruffer.*) Are the two quarters about the same?—Very much the same. In one quarter there were 151 houses, and in the other 141 houses.

19,993. (*The President.*) Were they similar houses?—Yes, exactly similar, and a similar class of people. The population would be almost exactly the same.

19,994. (*Prof. Wright.*) It works out that there is about the same percentage of attacks among the uninoculated persons, but a greater mortality than among the inoculated?—Yes; the number of attacks among the uninoculated was about the same, but the mortality was greater.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

FIFTY-SECOND DAY.

Tuesday, 21st February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Major M. A. T. COLLIE, I.M.S., called and examined.

Major M. A. T. Collie, I.M.S.

21 Feb. 1899.

19,995. (*The President.*) You are in the Indian Medical Service?—Yes.

19,996. And Superintendent of Matheran?—Yes. I have control of the station there, and complete control of plague matters.

19,997. (*Dr Ruffer.*) Will you tell us what has been your experience of plague?—My first experience in the first epidemic was chiefly administrative, for the Ratnagiri Collectorate. We simply tried to protect the district as far as possible from the introduction of plague by having passengers examined at the chief ports of call.

19,998. Where is that district?—It extends along the coast from Bankote Creek down to Vingorla.

19,999. How large is the district?—I forget how many miles it is.

20,000. Is that all the experience you have had?—No, after that I came up from Bombay, and I was placed in charge of the D. and E. wards in Byculla, in addition to my other work; and during that time I was Medical Officer of the Umarkhadi Jail.

20,001. I believe you say that there is difficulty in diagnosing certain cases of plague. Could you tell us what is the difficulty in diagnosis?—At first we were led to believe that the most stereotyped thing was simply an enlarged gland, and from that that there was no difficulty in diagnosing any case of plague. At first, however, I found extreme difficulty in diagnosing any case of plague at all. Even where we made *post mortem* examination of cases of enlarged gland, we could find none of the local signs of plague, even microscopically. If a case of sudden death was reported, or even if we saw people 48 hours before death, there was great difficulty in the diagnosis.

20,002. What was the chief difficulty in the diagnosis?—They appeared to be only suffering with fever.

20,003. Had the majority of cases an enlarged gland?—Not unless I saw them during life.

20,004. You saw a certain number of cases of fever without enlarged glands, which you diagnosed as plague?—Yes, after death.

20,005. Why did you diagnose them as plague?—Simply from the microscopical appearance.

20,006. Did you make a bacteriological examination?—I could not carry out the bacteriological examination, but I made a microscopical examination of every case I could.

20,007. In how many of the cases in your district did you diagnose the case after death?—In Hubli every case was diagnosed after death. I did not see more than three or four cases before death.

20,008. Were you in active service there, looking for plague cases?—Yes.

20,009. You think at the beginning most of the cases in Hubli were non-bubonic cases?—I cannot say that, for I did not see them till after death, except in about four cases.

20,010. Were most of the cases which you saw after death non-bubonic cases?—I could not find any bubo. When we came to look for the swollen glands that I saw during life, at the *post mortem* examination, I could not find them.

20,011. They had disappeared?—Yes.

20,012. Is that frequently the case?—I have not had sufficiently large experience to say.

20,013. How many *post mortems* did you make altogether?—During the time I was at Hubli I had 14 deaths, and I *post mortemed* every one.

20,014. How many had buboes?—I cannot give you that information. There was one case, for example, of a child who had several enlarged glands over the body, and I only found the ordinary *post mortem* plague appearances in one small gland of the neck, although the child had enlarged glands in the groin and the axilla, and there was none of that effusion of blood round the glands as we usually find, except in the cervical gland.

20,015. Was that a rapid case?—Yes, as far as we could gather.

20,016. Did you see any other cases like that?—I saw one woman which I had diagnosed as plague beforehand. She had an enlarged gland round the angle of the jaw, and she died within a few hours, but I could not find the glands after death.

20,017. It is your opinion that if you find a dead body in the street, unless you make a microscopical or a bacteriological examination, you cannot diagnose plague with certainty?—Certainly not.

20,018. In cases of plague pneumonia, did you find anything special after death?—No.

20,019. Did you see any cases of plague pneumonia at Hubli?—I got three cases there which showed *post mortem* signs, with ordinary complications.

20,020. Primary plague pneumonia?—I did not see them in life. In the obstetric hospital where I have been in charge for several months, I have seen cases come in there just moribund. They were brought in in a moribund condition, and as far as I could gather they had symptoms of plague.

20,021. Did you ever notice œdema of the front wall of the chest in cases of plague pneumonia?—No.

20,022. In the cases of plague without buboes, did you examine the other organs of the body for plague bacilli?—Always in the spleen or liver.

20,023. Did you find them?—If I did not find the glands, I found them in the spleen or liver before I gave my diagnosis.

20,024. Do you think there is much difficulty in diagnosing plague during life?—I think so.

20,025. Why?—It is very difficult to diagnose in many cases.

20,026. Why do you say in many cases?—I would not be prepared to swear to any case that I saw.

20,027. Unless you saw enlarged glands?—Or even then.

20,028. Why not?—Take the case which came up to Matheran, which is a small hill station four hours

Major M. A. T. Collie, I.M.S.

21 Feb. 1899.

from Bombay. He is the son of a Parsee gentleman. He travels first class. He was seized with rigors, and his temperature rose to 105. He gives me a history of chronic eczema of six years' standing. He had an enlargement of the femoral and inguinal glands in both groins, one was especially large, but he is convalescent now.

20,029. Is that a case of plague?—I cannot say, but I believe it to be, because he came from a house where dead rats were found and because another person was taken from that house to the Parsee Plague Hospital and died. I telegraphed down, as soon as the case came in, for pipettes and culture tubes, &c., but before they arrived he was convalescent, and Dr. Galeotti had injected 15 c.c. of Lustig's serum.

20,030. I suppose the diagnosis is difficult also in septicæmic cases?—Yes.

20,031. Do you think it is possible to diagnose a septicæmic case of plague in many cases, unless a bacteriological or a microscopical examination is made?—I think not.

20,032. Do you think the ordinary person who is in charge of a plague ward, who is not a medical man, would be able to diagnose a case of septicæmic or pnuemonic plague either during life or after death?—The first few cases I sent down from the Umarkhadi prison, I was very doubtful about. They were the first cases that occurred, and I think the first man had been 56 days in prison. I got Dr. Leon, who was working in my district, to come and take a little serum from the gland, and we sent the case down as one of plague. I sent the man to the Plague Hospital, and went round the next morning, and was told that he had had the glands for several years, and that it was not a case of plague at all, and I assumed that the patient was better. I asked how he was, but he was dead. This was the Arthur Road Hospital. We got our culture tubes there, we got characteristic cultures, and had microscopical examination in life, and yet it was pronounced by one of the staff of the Plague Hospital not to be plague.

20,033. Have you had recently any hospital experience of plague?—Not recently.

20,034. You have been to Plague Hospitals?—Yes.

20,035. Have you got any data to show that other patients besides plague are admitted in Plague Hospitals?—Certainly.

20,036. Could you give us examples?—When I had charged of the Narelwadi segration camp, people came down from Cutch. It was in October or November. One man had an enlarged gland which, on careful enquiry, I found had existed probably since childhood. After satisfying myself that it was not plague, but simply intermittent fever he was suffering from, I discharged him from the segregation camp after keeping him five days under observation. Within three hours one of the spies, or whatever they were, who were employed by the Plague Commission, seized this man while he was eating his food, and sent him to the Plague Hospital.

20,037. Had he fever at the time?—No.

20,038. The diagnosis was based simply on the enlarged gland?—Yes. I traced him to the Plague Hospital and turned up the case. He was treated entirely as a case of *pestis ambulans*. The man went to work within a day or so after his discharge from the hospital, after being there for only four days. He had no plague.

20,039. Have you seen cases of relapsing fever in Plague Hospitals?—I have seen cases of relapsing fever, but not in hospitals.

20,040. Have you seen any cases of malarious enlargements of glands admitted as plague patients?—Only that one that I mentioned just now, but not any others to my knowledge.

20,041. Have you ever seen cases of syphilitic glands or gonorrheal glands admitted as plague?—I have not seen them; I have heard of them. I have no personal experience.

20,042. I believe you are a strong advocate of "the "importance of quarantine versus surveillance and "inspection as examplified in the occurrence of plague "throughout the Ratnagiri Collectorate in the first "year's epidemic." Can you give us any evidence as to why you prefer quarantine to surveillance and inspection?—It is based entirely on the fact that unless you can observe a person for 10 or 12 days you do not know whether he is in the incubation stage or not. He passes up-country, and in the Ratnagiri Collectorate there were 300 odd cases of plague and nearly half of them were indigenous.

20,043. How could you establish a perfect system of quarantine in the Ratnagiri Collectorate, for instance?—Only by allowing the people to land at certain ports.

20,044. Could you prevent them landing in other places?—If the authorities in Bombay Harbour only give clearances to specified ports. I think it is one of the districts that could be most easily managed. It is entirely a coastal service, and people get down by steamer or by native craft, and there are very few roads from the other side of the Ghats.

20,045. Cannot they go down by land?—It is very inaccessible; all travel by sea.

20,046. Supposing they knew that the sea route was closed, would not they come by land?—The journey is so long that they would not do it. It practically embraces quarantine. The nearest station by land is Kolhapur, which is 40 miles from Ratnagiri frontier.

20,047. That is a day's journey?—You will not do it in a day.

20,048. Say two days?—They have to go up and down the Ghats.

20,049. I want to know how you can protect a large tract of country like a Collectorate. How many men would you want to protect a Collectorate by quarantine?—The proposal was that native craft should only get clearing papers for certain ports.

20,050. What prevents them from going into other ports?—The Customs authorities along the coast.

20,051. I suppose there is a certain amount of smuggling there like everything else. Why could they not smuggle plague cases?—They might do it. They might land them on the shore.

20,052. Supposing you had quarantine, do you think the people would try to avoid the quarantine measures?—I think they probably would.

20,053. You say you have seen "the occurrence of cases in quarantine camps up to eight days, and in one case 12 days"?—Yes.

20,054. Were the people disinfected before they entered quarantine camp?—Yes.

20,055. Were there any other cases of plague in the quarantine camp at the time?—One was in what you might call an "observation camp" where the people had been taken from an infected area. The other case of 12 days was a case that came up from Goa and was put into a quarantine camp because we did not know the condition of Goa at the time.

20,056. Did you disinfect the clothing?—Yes.

20,057. Did you disinfect every person's clothing?—Every person's clothing was disinfected by the steam steriliser.

20,058. There have been no cases of plague in the camp?—No.

20,059. You advocate "early removal of people from "infected areas with liberty to carry on their daily "avocations out of the health camps"?—Yes.

20,060. You also say there are "difficulties in pronouncing when an area or town may be declared free, as exemplified in the case of Hubli"?—Yes. There was a very careful census taken there, and a very careful system of inspection of houses &c., and as far as we could find out no cases occurred except at intervals. First there was the 9th and 10th of January, then you pass on to the 18th, which is a doubtful case. It is put in as a case, but it was not recognised as occurring until the 30th, that is 20 days.

20,061. May not that case have got plague somewhere else and not in Hubli?—No, we are certain about that.

20,062. Why?—Because he was not out of Hubli.

20,063. Supposing a case of plague had come to Hubli and died, could you exclude any possibility of Hubli being infected?—He was known by the census; he was in the roll-call every morning.

20,064. But supposing a man had come from outside to Hubli, and died from septicæmic plague, which is difficult to recognise, could you exclude that possibility?—Except that all the roads were controlled. Of course, it is impossible to say that they did not get there; you cannot exclude it.

20,065. Can you give us any examples of plague being introduced into a community by means of clothing?—Yes.

20,066. Would you give us the details?—The first case that came to my notice was at a village of Ladghar, which is about eight miles from Hurnai in the Ratnagiri collectorate. A Bhandari, one of the fisher class, had lost his wife, and he came to Bombay and took down her jewels and her clothing. Within a few days after his arrival in the village dead rats were first observed, and then the first person to suffer was an aunt who lived in the same house, and then a nephew, and then the son, and finally the Bhandari himself who had brought the infected clothing. He died, and altogether in that village we had 47 attacks and 39 deaths.

20,067. How long after the clothing was brought down was this first attack?—I had to inquire from a Hospital Assistant, who was on duty there, and he says in an indefinite way that dead rats were first observed two or three days after the man came down from Bombay.

20,068. Is there no possibility of plague having been introduced into that village in some other way?—They are all people who live by fishing and toddy drawing and no one had left the place except this man.

20,069. Can you tell me what the total mortality of that village had been in the preceding weeks?—I cannot.

20,070. Was the total mortality of the village raised?—There was no report of it. Inquiries were made in all these cases, and there was no unusual mortality.

20,071. Rats were found two or three days afterwards?—Yes.

20,072. The clothing must have infected an enormous number of rats very quickly?—I cannot tell you that.

20,073. I can understand a great many rats being found dead a week afterwards, but it is difficult to believe it was found within three days?—You know what a native's statement is; it is possible that plague had existed for some time before we had intimation of it. A native is always very indefinite with regard to his time statements.

20,074. Have you any other evidence of plague being carried by clothing?—At a village called Guhagar, down the coast, a boy who had recovered from plague was brought down by his friends, and stayed at an aunt's house. They had a feast of some kind there, and it was said that he brought down the clothing with which he was discharged from the hospital. Ten days afterwards his aunt sickened with plague and died and then one of her children.

20,075. There was no plague in that village?—No.

20,076. Did not any rats die?—No. There was another case at Hubli. The whole of the infected area had been cleared out, and this man had been 20 days up in the health camp. The whole of this area was under the charge of the police. He had heard that I wanted to destroy his house, which was next to the first infected house in that area, and he went back to his hut to remove some clothing from there, and within 11 days from that occurrence he sickened from plague in the health camp and died. He had been 20 days altogether (supposed to be) in the health camp.

20,077. There was no other case of plague in that health camp?—No, the whole of that had been cleared out.

20,078. Were the health camps under the observation of medical men?—Yes.

20,079. Every day?—I went up every day; there was a roll-call every evening and morning.

20,080. Had the clothing of the people going into that health camp been disinfected?—Yes, all through the steam steriliser, as far as I could say.

20,081. Are you certain of that?—Officers were appointed to see that it was done.

20,082. Who are the officers?—Lieutenant Keelan had charge of the disinfection, and there was a Hospital Assistant who would not allow things into the camp unless a chit was given stating that the things were disinfected.

20,083. Have you any other examples of plague being communicated by clothing?—No.

20,084. You say you have "examples of plague being "introduced into a community by means of clothing, "and of a man contracting plague by surreptitiously "revisiting a cleared area"?—Yes. This man, as far as I could gather from his wife, had removed a pagri from that place, and whether it was from the pagri or not I cannot say.

20,085. You think it is important that railway authorities should look after their own employés?—Certainly.

20,086. So as to prevent the spread of plague from one district to another, because they travel through large tracts of country?—Yes. As an example, I may say that a railway guard was found at Hubli station travelling from Belgaum to Bezwada. His father and his brother and his sister-in-law had all died of plague, which was not diagnosed as plague, at Belgaum. At the railway station at Hubli he removed his wife and his mother and they died of plague in a few hours. This man travelled down from Belgaum with a pass to Bezwada.

20,087. Did he himself suffer from plague?—No, and the children did not suffer.

20,088. How did the disease reach his mother and wife?—His mother and wife died in the railway quarters.

20,089. You believe in "the importance and necessity "for the medical officer being alone the organiser and "director of all plague measures." Can you tell us what you base that on?—The whole training of the medical officer is to deal with disease. He knows the disease and he knows how best to deal with it, and he knows the people. At the time I was working here in Bombay I was constantly interfered with; for example, I got a hard and fast rule laid down to me that if persons had a temperature of 102 degrees in the segregation camp, I was to send them to the Plague Hospital, whether I thought they had plague or not. I do not think that is an order that should be issued to a qualified person.

20,090. You think that was a mischievous rule?—Most certainly. In many cases, if I had acted upon it, I should have sent malarial fever there; but I never did act upon it.

20,091. Can you tell us any other rules that you consider unnecessary?—When they first introduced the order as to clearing out persons from areas in which dead rats were found, I regarded it as a most rational thing to clear the whole of that area out. I cleared out from one chawl near Bombay about 80 people, and I got an order the next morning that I was not to do these things in such a wholesale manner; that I should simply take the room in which the dead rats were found, and the two neighbouring rooms.

20,092. Where were the two neighbouring rooms?—One on each side of the room on which the dead rats were found.

20,093. Do you know the reasons why they said the two neighbouring rooms?—I cannot give you the reason.

20,094. Can you give us any other instances?—I think the medical officer should be allowed to control all these things himself.

20,095. And you think, probably, that the difficulty of diagnosing cases of plague is also in favour of your contention that the medical officer should be in charge?—Certainly.

20,096. (*Mr. Hewett.*) Were you at Hubli when the census was taken there?—No.

20,097. Who took it?—Dr. Meyer.

20,098. You refer to a case in January 1898, which took place 23 days after the one immediately before it. Do you attribute the infection in this instance to the man having got infected in a house which contained the poison?—After careful inquiry, I found that he went back there with his wife.

20,099. Is not that the man that went back from the segregation camp?—Yes, the same man.

20,100. Is that how you think he got infected?—I believe he stayed there all that night. The evidence is that he was drunk that night, and he must have slept there.

20,101. Raga Appaji is the man?—Yes.

Major M A. T. Collie, I.M.S.

21 Feb. 1899.

20,102. (*Mr. Cumine.*) You spoke of a Bhandari boy. Are they fisher people, or toddy tappers?—I think they do both.

20,103. What was the interval that elapsed between the arrival of the boy and your hearing of the death of the woman?—We heard of the death of the woman about a week after her death. We had a system of weekly reports.

20,104. Who brought the boy down from Bombay? Did some friends come with him, and deposit him and go away again?—Some Bhandaris came with him, and they went up the coast, and came back again. They were owners of a native craft, and they brought him down from Bombay and deposited him at his aunt's house, and went away.

20,105. Can you exclude the possibility of their having plague in their bodies when they deposited him and went away?—No, I cannot exclude that.

20,106. Is not there an observation ward for doubtful cases attached to each of the public hospitals in Bombay?—I cannot say.

20,107. As regards the man whom you released from the Narelwadi camp, and who was sent to the hospital, can you say for certain whether he was put into the plague ward, or into the observation ward?—I was told that he was put into the plague ward, and that he was treated as a case of *pestis ambulans*. I went to the hospital and saw the charts and notes of how he was treated.

20,108. What did you think it was at first?—I had no doubt about it being malaria, and I kept him in the Narelwadi observation camp. He had fever one day, and then an intermission, and then he had another attack of fever. I discharged him as soon as I was satisfied that it was malaria.

20,109. When a district is very heavily infected like Satara, with many infected villages, how could a medical officer manage everything there himself?—He must be the organiser; he cannot be everywhere himself. He must be the administrator in all these things, and, as far as possible, he should have skilled Hospital Assistants—the same as in cholera; you cannot be in every village when cholera breaks out.

20,110. I think you said that medical men are not invariably able to diagnose a case as to whether it is plague or not?—I think it is very difficult.

20,111. What are the other respects in which you think they are superior to, say the Revenue Officers or the Police Superintendents?—Their whole medical training is to deal with disease; they are not likely to act rashly, like a person belonging to the laity, who is not accustomed to deal with it.

20,112. I think you said there was a man from Goa who developed plague in the quarantine camp after 12 days?—Yes.

20,113. Were there any plague cases then in Goa?—We could not find out. I do not know whether anybody knows yet.

20,114. Has plague ever been officially declared in Goa?—No. I heard there was a great deal of sickness and large mortality. The Goanese told me that themselves.

20,115. (*Prof. Wright.*) Were you in charge of the Umarkhadi Jail when the inoculations were done in January last year?—Yes.

20,116. How long did you continue in charge of the jail?—I gave up the appointment on the 4th January, but I had been in charge of it for three months.

20,117. The inoculations were done about the 1st?—Yes.

20,118. You have no personal knowledge of what happened afterwards?—No.

20,119. Did you supervise the selection of the candidates for inoculation?—I was present there. A bell was rung, and the prisoners marched in. They were mustered in a row, and there was no selection made.

20,120. Were all the prisoners allowed to be inoculated if they so desired?—They were told they were going to be inoculated, and that if any prisoner objected very strongly he would not be inoculated.

20,121. Was every second man inoculated?—Every second man, unless they had fever, or were very old and debilitated, or objected. I think there were not two objectors in the whole lot.

20,122. I understand that some of the prisoners worked at outdoor, and some at indoor occupations?—No, not in Umarkhadi.

20,123. Were they all engaged on indoor occupations?—All indoor.

20,124. Were they all employed in the same occupations?—Not all the same. I had not charge of the employment of prisoners, but I know that some do grinding, some do the teasing of oakum, some treadmill, and some the making of mats, and such like.

20,125. Were the occupations of the inoculated different to the occupations of the uninoculated?—No. There was no distinction; the occupations are changed very frequently, so as not to allow them to mingle too much together.

20,126. Did you see the febrile reactions that followed upon the inoculation?—I took the temperature in every case.

20,127. Did you find any very high temperatures after inoculation?—I think the average temperature was 101 and 102; some went up to 104.

20,128. Are there any records of these temperatures?—Yes, there must be on the files in the hospital.

20,129. Did you take the temperature of every person inoculated?—Every temperature.

20,130. Did you find much difference in the reactions?—Yes, some had very little reaction, and some very strong reaction.

20,131. Where are these records to be got?—They should be on the files of the hospital. I told the Hospital Assistant to keep them, but he is changed now, and I do not know whether they would be accessible now.

20,132. (*Dr. Ruffer.*) Do you think plague is a more easily diagnosed disease than any other acute infectious disease?—Do you mean small-pox or measles?

20,133. Yes, or any other?—I consider it is far more difficult to diagnose plague.

20,134. (*The President.*) If it be more difficult to diagnose, is it not your opinion that the work of diagnosing should be done by trained diagnosers, such as medical men?—Yes.

20,135. (*Dr. Ruffer.*) You think most men now negaged in plague work are absolutely incapable of diagnosing a case of septicæmic plague?—I think so.

(Witness withdrew.)

Capt. C. H. L Meyer, I.M.S.

Captain C. H. L. Meyer, I.M.S., called and examined.

20,136. (*The President.*) You are a Doctor of Medicine, I believe?—Yes.

20,137. I think you can give us some information with regard to the first outbreak of plague at Hubli?—Yes.

20,138. (*Mr. Hewett.*) I believe you were only employed during the first epidemic at Hubli?—Yes.

20,139. That was a very small one?—Yes.

20,140. Was the first case in a railway chawl?—Yes.

20,141. Did you trace how the infection came there? As far as we could trace it, it seems to have been brought from Poona by railway employés. Some railway employés had gone on leave to Poona, and they brought the infection with them on their return.

20,142. When we were there a short time ago it seemed to be possible that the first infection was due to the arrival of a family from Sholapur: do you think that that is likely?—I investigated that. I did not put any reliance upon it.

20,143. You think, then, that railway employés brought it from Poona?—Yes.

20,144. Was the railway chawl at that time in an insanitary condition?—Only, or chiefly, as regards ventilation. The ventilation was extremely bad. The chawls were placed together, and the windows were small. The weather was cold, and the houses were

shut in by verandahs. The ventilation, both external and internal, was very bad; it was very deficient indeed. The other sanitary conditions were fairly good.

20,145. How many cases occurred in the railway chawls?—35 altogether.

20,146. How long after the detection of the first case did you evacuate the chawl?—The first case occurred about October the 10th; I did not arrive there until the 27th, and we commenced to evacuate about October three or four days later.

20,147. How long did it take to complete the evacuation?—Four or five days.

20,148. At what time was the cordon placed around the railway chawl?—On the 23rd of October.

20,149. Did you find the cordon efficient?—We had a large force of police. They were native police, however, and we could not thoroughly trust them.

20,150. Do you remember how many police you had?—I think we had about 60 on duty constantly.

20,151. Notwithstanding that, people came into the chawls and got out of the chawls, did they not?—The way plague was once carried into Hubli, was this. A friend of a policeman came to see him. This policeman was on the cordon, and his visitor slept a night in the cordon—I really believe in one of the empty chawls. The police were in the habit of going into these empty buildings and sleeping in the verandahs of the chawls: it was very cold. This visitor got infection there, and carried it into the town.

20,152. Did any people escape from the chawls to the town and get infection?—No.

20,153. Did not a Goanese do so?—No; the only case we could trace was the one I have mentioned.

20,154. Did you find that the moving of the inhabitants outside their houses had the effect of stopping the epidemic in the chawls?—Yes.

20,155. How long did it take to do that?—The epidemic in the chawls was practically over by December the 13th.

20,156. That was six weeks after you had taken the people out?—About a month or five weeks after they had all been taken out.

20,157. What was the number you had taken out of the chawls?—About 1,200 people.

20,158. You think it is very important to prevent people from returning to infected houses after evacuation?—Yes; I was on plague duty for a short time at Lanauli, and then also at Hubli, and I found that if you disinfect houses ever so thoroughly, and let people go back again into the houses after a week or a fortnight, they frequently got plague again, as the houses are still dangerous.

20,159. Could you exclude all possibility of infection from outside in this case?—I could not, certainly.

20,160. How long would you keep the people out of their houses?—Until the epidemic was over.

20,161. Have you anything to say as to the various methods of disinfection?—I do not believe very much in the disinfection by solutions; I think it is quite impossible to reach every crevice in a house and thoroughly disinfect it in that way; I would rather trust to taking off the roofs of the houses and letting in the sun and the air. The burning out of the houses is better still.

20,162. What do you mean by burning out the houses?—In the railway chawls at Hubli, I unroofed the houses, and put into each separate chawl a quantity of combustible bamboo material and grass and set that alight. The interior of the chawls was so hot after this treatment that you could not go into them for two or three hours after the fire had burnt out. That method, I think, must be efficient.

20,163. When a disinfecting solution is used, do you think it is necessary that the whole of the roof should be disinfected?—I always thought so.

20,164. You think there is a possibility of infection from the roof?—Yes, rats run about in the roofs.

20,165. There was a scheme started in Hubli, I believe, for detecting plague cases?—Yes. The town was divided up into a number of wards. There were about 12,000 houses in Hubli and we divided the town into 120 parts. And over each lot of 100 houses we put a Supervisor. This man took the census of the houses and he visited them every day. He made reports of any new arrivals at these houses, and also in cases of death and of sickness.

20,166. During your time were many cases of sickness reported by the Supervisor?—Yes.

20,167. Lieut. Keelan who followed you, told us yesterday that the majority of cases in Hubli were reported after death; that would rather show that this system of supervision is not very effective?—It was effective in discovering the plague cases after death, not very effective in discovering them before death.

20,168. Do you know how the town of Hubli became infected in the second epidemic?—No; I could not tell you. I only know after I gave up charge at Hubli on January 9th, there were no further cases of plague until January the 30th. After that there were dropping cases all through February, March, and April, and then the cases gradually increased and the second epidemic was at its height in July.

20,169. Were you in Hubli at the time the Mahratta Gali was burnt?—No; before I left we evacuated the Mahratta Gali, and the houses all around the quarter which we supposed might be infected.

20,170. So far as we could ascertain when we were at Hubli the outbreak seemed to have stopped with the Mahratta Gali, and the second outbreak seemed to have been due to fresh infection; do you think it is likely to be possible?—Yes; fresh infection would be very probable, because infected Belgaum was not very far away, and there were other places not very far away where there was plague. The people were travelling about a great deal, and there was constant danger of infection being imported from these places, especially from the Belgaum district.

20,171. You know nothing about inoculation at Hubli?—No, it was after my time.

20,172. While you were there was the census of the inhabitants taken?—Yes.

20,173. In what month?—In December.

20,174. Was Capt. Leumann there at the time?—No.

20,175. Under whose direction was it taken?—Under the directions of the Collector.

20,176. Was any European employed in connection with the taking of it?—No, I do not think so.

20,177. During your time there, did anything come to your knowledge to make it appear that people had left the town?—No; they did not leave the town much in my time; there was no scare then.

20,178. Were people coming into the town from outside?—They were leaving the town and coming into the town in the usual way. There was no scare or panic—nothing to frighten them.

20,179. Do you think that at the time the census was taken the population would be normal?—Yes, I think it was found to be so by the figures. The normal population would be something like 48,000 or 52,000, I cannot remember which.

20,180. You had nothing to do with taking the census?—No.

20,181. The Supervisors took it themselves?—Yes.

20,182. How many houses was each Supervisor responsible for?—One hundred.

20,183. Do you know whether for the purpose of tabulating the census returns, the Supervisor visited each of these 100 houses on one particular day?—I cannot say that he took his census on one day; it was probably done within a week.

20,184. (*Dr. Ruffer.*) When you speak of efficient disinfection not being sufficient to stop plague in a house, you mean disinfection by heat?—I mean particularly disinfection by solutions. I had an experience of that at Lanauli; I carried it out under my own supervision very thoroughly; in fact, I worked the pumps myself. I found that when I let the people into the houses they got plague.

20,185. What solution did you use?—Perchloride of mercury.

20,186. Acid?—No; I dissolved it with sodium chloride; I used a strength of about 1 in 800.

20,187. Did you use it in pumps?—Yes.

20,188. Did you make the solution yourself?—Yes, so as to make sure it was correct.

Capt. C. H. L. Meyer, I.M.S.

21 Feb. 1899.

20,189. Did you find that the sublimate dissolved easily?—I made it over night, and left it to stand about 24 hours.

20,190. Did you find that it had dissolved by the next morning?—Yes.

20,191. What temperature did you get in the chawls by lighting the fire and burning the bamboo material?—It was a very high temperature. It was so high that you could not possibly go into the interior of the chawls

20,192. I want to know what you mean by a very high temperature. If the temperature was up to 60 or 70 you could not go into the room?—You could not face the heat. If you went to the door while the fire was still glowing, or even an hour after it had gone out, you could not enter the room.

20,193. Have you any idea what the temperature actually was?—No.

20,194. Do you know what degree of dry heat is necessary to kill the plague bacillus?—I do not know.

20,195. (*Prof. Wright.*) Was perchloride of mercury the only antiseptic you used?—Yes.

20,196. You did not try carbolic acid?—No.

20,197. Can you instance any particular cases which led you to doubt the efficacy of the disinfection?—I could not specify particular cases, but I know from my experience at Lanauli, as I told you just now, that when I had thoroughly disinfected houses there, and let the people return to those houses, after a week, they got plague in those disinfected houses.

20,198. Were all things turned out of the houses when they were disinfected?—Yes.

20,199. Were clothes disinfected?—Yes, everything.

20,200. Did you put the clothes in the solution of perchloride of mercury too?—Yes, and the furniture was all disinfected. Others have had similar experience in Bombay, and it was found that disinfection in that way was not efficient.

20,201. You took every precaution you could think of and disinfected clothes, floors, and roofs?—Yes, the the disinfection was very thorough; we tried to cover every spot. I attended to the disinfection of the houses and the clothing myself.

20,202. Have you any theory by which you can account for the want of success which attended your disinfecting operations?—Except that I think it is impossible when disinfecting the houses, to reach every crevice and corner in the woodwork and the stone work in the houses with disinfectants like that.

20,203. (*The President.*) When you disinfected by sunlight and fresh air and then allowed the people to re-enter, did you have any cases of plague in houses so disinfected?—The people never re-entered; the roofs were taken off and the houses made uninhabitable.

20,204. For what period of time?—In the case of chawls at Hubli they remained so until I left; I do not know whether those chawls have been re-entered or not.

20,205. You have no instances in which, after this method of disinfection, the houses were re-occupied? I do not know any instance.

20,206. You can hardly say whether it is efficacious; you cannot compare it with chemical disinfection?—I think it very important to keep the people out of the houses. After we had disinfected in that way, the doors were screwed up, so that the inhabitants could not possibly enter.

20,207. You have expressed an opinion that certain insanitary conditions were very favourable to the development and spread of plague?—What I meant was bad ventilation; especially want of sufficient air. The houses in Hubli and in the railway chawls were rather remarkable in that way. They were so very dark, even for an Indian city. The windows were very small and usually sealed up. There were a great many verandahs to the houses which prevented the circulation of air. The internal ventilation of the houses was extremely defective. In other respects the sanitary conditions of the houses in Hubli were excellent for an Indian city.

20,208. Were the dwelling-rooms clean?—Yes.

20,209. Was there any overcrowding?—Not greater than in other Indian cities; they are all overcrowded.

20,210. Overcrowding would tend to do what you say was so injurious—tend to vitiate the atmosphere, would it not?—Yes.

20,211. (*Prof. Wright.*) Did you lime-wash the houses after you disinfected them?—Yes, with solutions.

20,212. Do you not think that the application of lime is calculated to counteract the goods effects of the perchloride of mercury?—I did not think so at the time, but I do think so now.

20,213. Are the walls of the houses at Hubli made of mud, or of a mixture of mud and lime?—There is usually a mixture of lime in the walls, in these railway quarters, certainly.

20,214. Do you think that your ill-success in disinfecting might have been accounted for by that fact?—I had no bad success in disinfecting Hubli. At Lanauli I had to deal with mud walls. In Hubli itself, I carried out that disinfection, but I disinfected also by fire. In addition to that, I kept the people out of their houses.

20,215. Then it was your experience at Lanauli, which led you to doubt the efficacy of your disinfecting operations?—Yes.

20,216. What did your disinfecting operation consist of?—I used solution only, and did not disinfect by fire; I also limewashed the places, and I came to the conclusion from the experience I had of it in Bombay, that such a method was not reliable.

20,217. Do you think that the giving off of ammonia from cow-dung floors is a circumstance which might vitiate your disinfecting operations?—That would be an element.

20,218. Were any steps taken to neutralise the ammonia?—No.

20,219. (*The President.*) Were the floors cow-dung floors?—Yes, in almost all instances.

20,220. Supposing the materials of the floors consisted of a large quantity of albumenoid substances that would oppose the penetration, as it were, of the mercuric chloride, would it not?—Yes, it would.

20,221. (*Mr. Cumine.*) When you found that one application of perchloride of mercury did not appear to be sufficient to make the houses safe, did you try and repeat the application day after day?—No.

(Witness withdrew.)

Mr. W. T. Morison, I.C.S.

Mr. W. T. Morison, I.C.S., called and examined.

20,222. (*The President.*) You are in the Indian Civil Service?—Yes.

20,223. What is your position?—Collector of Land Revenue, Customs, and Opium, Bombay.

20,224. (*Mr. Cumine.*) You were Collector of Sholapur in 1897?—Yes, till January 1898, from January 1897, one year.

20,225. You can tell us then about the severe visitation of plague which took place in Sholapur city. What month did it begin in?—It began outside the town in September, and it spread to the town itself in October.

20,226. How long did it last?—It was practically extinct from the town of Sholapur by the end of January 1898, but in the meantime it had spread outside. I am merely speaking of the town itself.

20,227. Is it known where the infection came from?—It is believed to have been brought from Poona.

20,228. By sick persons, or by clothing, or what?—As far as we could ascertain it was brought by a Goanese servant, who came to an officer's house in the cantonment. How it was brought by him we do not know, but his was actually the first case that occurred. He had been to Poona.

20,229. Please give us a short description of the epidemic in Sholapur?—Plague first broke out towards the end of September 1897 in the Sadr Bazar, an isolated, compact suburb about half a mile from the town proper, but within Municipal limits. The suburb could have been easily evacuated at once, as the inhabitants were most of them of the lower and poorer classes, and subsequent experience showed that this would have been far the wisest step to take at first. But we were new to plague operations, and thought that wholesale evacuation was too drastic a measure, besides being likely to spread the disease elsewhere. So we decided to try and confine the plague to the Sadr Bazar by drawing a cordon of police round it. The place was well suited for this, it was compact, with open ground on all but one side, and we had what seemed a sufficient number of police.

20,230. Was the attempt to keep the people in by a cordon of police successful?—It was a complete failure. The people began to melt away like mist, and we found that we were only guarding a gradually emptying suburb. In the first place, we had to let most of the healthy adults go every morning to their work. We issued daily passes to them, but refused to let their women folk and children go, hoping that this would bring the men back every evening. But the attraction was not strong enough, and most of the men remained away and were soon followed by their families, who arranged somehow or other to get through the cordon, by procuring passes under false excuses, evading the posts by night, or bribing the sepoys. Meanwhile the plague was raging among those that remained, and the absolute necessity for complete evacuation then became apparent. This was carried out about 15th November, the people being collected into a camp known as the Moti Bagh Camp, a mile off. As soon as we got the people into the camp there was a sudden and marked decrease in the number of cases among them, and in about a fortnight they were almost free of plague. Before this, however, the plague had spread to the city, and by the beginning of November a number of cases were occurring daily. Sholapur is a place of 62,000 inhabitants, and the total evacuation of it was a work of such magnitude that it hardly occurred to us at first. We began by evacuating the worst infected quarters, and from the weekly reports I find that by the 27th November four quarters containing 400 houses in all were evacuated.

20,231. Did you find that partial evacuation, evacuation of the infected quarters, was sufficient to prevent the spread of plague in the town?—So far as we found, it prevented it spreading quickly, but it had not the effect of absolutely stopping its spread. We found that it spread it spite of evacuation. It was impossible, however, in spite of every precaution, to prevent some of the inhabitants of these quarters taking refuge with friends in other parts of the town, and the plague continued to spread until every part of the town was infected. Evacuation was then carried on on a larger scale, and early in December we determined to evacuate the whole town, and an order was issued that by the 31st December the town was to be empty. At the same time a large camp was laid out in a convenient open site between the town and the railway station, and another to the east of the town. In these sites, streets of shelters made of gunny bags were erected at Government expense (each shelter costing Rs. 5, I think) for the poorer people, and sites were pointed out to the well-to-do, where they could put up their own huts. Large numbers, too, went and lived on the fields outside the town. When once the people saw that total evacuation was decided on, little pressure was wanted to make them leave the town. There was naturally a rush for the best places in the new camp. The town, too, with its many empty and silent streets, often tenanted only by an occasional corpse, had an uncomfortable and haunted feeling about it at night, which was increased by exaggerated rumours that gangs of dacoits from adjacent Hyderabad territory were about to descend on it.

20,232. Did the town ever become completely empty, and if so, on what date?—It became completely empty by the end of 1897.

20,233. Can you show us by figures what the effect of this total evacuation was?—The effect of this total evacuation can be best realised from the study of the weekly returns of plague cases. The following table shows these returns from the end of September to the end of March:—

TABLE showing the PROGRESS of PLAGUE, Week by Week, within MUNICIPAL LIMITS of SHOLAPUR CITY, including all SUBURBAN HEALTH CAMPS.

Week ending	Imported.		Indigenous.	
	Cases.	Deaths.	Cases.	Deaths.
1st October 1897	—	—	13	9
8th "	—	—	6	4
15th "	—	—	26	8

These figures, of course, include all cases among those living in the camps and fields outside the city. Little comment is necessary, as the figures speak for themselves. The sudden drop in the number of cases came in the week ending 24th December. The town was practically empty by the middle of December, only a few who had to make special arrangements for the removal of their valuable property remaining behind till the end of the month.

20,234. Did the camps enjoy immunity from plague?—Almost complete, and this was one of the most striking features of our operations. The largest camp, known as Pothepur, with over 10,000 inhabitants, was not more than 200 yards from the town walls. Yet with the exception of one or two cases, most probably of people with plague in them when they came to live in the camp, it was entirely free from plague.

20,235. Before people were admitted into the camp, and after they had been admitted into your camps, what precautions were taken?—Most careful precautions were taken in the camp under the supervision of Mr. Pratt, Assistant Collector, who was placed in charge of it; all new arrivals were made to bathe their bodies and clothes in disinfecting baths, and there was an inspection of each hut twice daily for plague cases. Our regular camps were almost entirely free from plague from the first, and that, too, at the coldest time of year, when the disease is generally found to be most vigorous in towns.

20,236. Did you find that bad results followed on the emptying of a plague-stricken town?—The plague, of course, spread outside.

20,237. I mean as regards the neighbouring villages?—It spread to them gradually, but to no very great extent. It went on outside for a long time after it was practically extinct in the town. I am of opinion, however, that in the case of Sholapur the plague was not spread so widely under our evacuation system as it would have been had we not gone in for evacuation, and that this will always be the case in similar circumstances. Before we decided on a general evacuation, it was found that a large number of plague-stricken people and their friends were leaving the town and hiding in the villages. In spite of guards placed on all roads, they managed to escape, generally at night: and every morning corpses were found lying on the roads leading from Sholapur and in the surrounding fields. What happened was that as soon as a case occurred in a house, all the inmates at once fled to escape infection and segregation. It was impossible, by merely putting

Mr. W. T. Morison, I.C.S.

21 Feb. 1899.

guards on the roads and patrolling between them, to stop the people getting away; they would wait till night and creep through the fields and hedges, anywhere and in any way to get away. Nothing less than a fence round the whole town would have prevented them. Thus many of the sick and contacts, not detected by us, escaped to the villages, while the healthy, as a rule, remained behind. When only a partial evacuation of the worst quarters was being carried out, it was the interest of all the neighbours to help these fugitives to get away, so that their quarters might not be ordered to be evacuated. When complete evacuation is resorted to, there is not, in my opinion, the same danger to surrounding villages; a few more healthy people may take refuge in them, but there is not the same inducement for the infected or contacts to go; they are already undergoing the discomforts of *camp* life, and the segregation camp is not much worse, perhaps rather more comfortable; and it is no one's interest to help them to escape.

20,238. Would you tell us the chief conclusions you formed from your plague experience?—The conclusions which I would beg to submit to the Commission as the result of my experience in Sholapur are as follows:—

(*a.*) The immediate and complete evacuation of all villages, and of towns up to 40,000 or 50,000 inhabitants, when this is considered possible, is the best way of treating an outbreak of plague.

(*b.*) *Before* commencing the evacuation of a large town, complete arrangements should be made, and the necessary staff sent to their posts, for the thorough inspection of all surrounding villages, say, within 30 miles, and for immediately evacuating any village where plague is discovered.

(*c.*) Partial evacuation of towns and villages by clearing out the worst infected quarters only is not recommended where complete evacuation is within the bounds of possibility. It may reduce the mortality and make the disease move slower, but it will not stamp it out.

(*d.*) The system of keeping the inhabitants of an infected town or village to their houses by drawing a cordon round the place is not recommended, and will, it is believed, prove a failure, except in the case of small villages.

20,239. (*Mr. Hewett.*) Is it the case that before you evacuated any part of the town there had been a large number of cases of plague?—We started by slow evacuation. We began with houses only, and then we went on to quarters. We extended it gradually to small quarters of streets, and then to the whole town. I cannot exactly tell how many cases had occurred while these partial evacuations were going on.

20,240. Did you have contact camps and health camps?—We had.

20,241. Voluntary as well as compulsory?—They were all compulsory.

20,242. What was the largest number of cases, firstly, in the health camp, and, secondly, in the contact camp, at any one time?—I am afraid I cannot say that.

20,243. Can you give any estimate?—We had three or four health camps round the town.

20,244. Can you give us an approximate estimate of the proportion of the 62,000 inhabitants of the town who were in these camps?—I should think about 25,000 at least.

20,245. So that about 35,000 persons went elsewhere?—A great many went to their own lands in the vicinity of the towns. Sholapur is an agricultural town, and cultivation comes close up with it. Anyone with lands and fields would go with their friends and stay in their own fields. We had not any actual check over these small habitations in the fields, though they were always inspected for plague cases, but we could hardly say they were under our control; they were only inspected.

20,246. What proportion of the 62,000 inhabitants of Sholapur went, in your opinion, to other places?—There was a large exodus at the beginning of the plague. I should think about a quarter of the population probably had gone before the plague became bad at all.

20,247. And do you think that these people would have gone, whether you took any measures, or whether you did not?—I expect so. I do not think they could have been stopped. Sholapur is close to the Hyderabad frontier, and a large number fled across the border merely at the prospect of plague restrictions, as they thought in Hyderabad territory they would be outside our control entirely.

20,248. When you advocate complete evacuation of towns up to 40,000 or 50,000 inhabitants, you contemplate the possibility of a certain proportion of the population of such towns flying away into other localities?—Yes, I should think about a quarter. Of course, this is only a rough estimate; but I think that whenever plague appears at a place an exodus always begins at once, and goes on slowly and silently, so that, when it comes to checking the actual houses, you will always find that there are a great many empty.

20,249. Do you think that exodus is due to the fear of the plague, or to the fear of the measures taken to suppress it?—I think the people are afraid of both. I do not think it can be attributed solely to one or the other; I think equally to both.

20,250. Do you find that any particular classes left the town in the early stages of the epidemic?—Such as could travel easily, and had not to stay at home to earn their daily bread, could, of course, go; and those who had houses and friends elsewhere would always go at first.

20,251. Do you think that any measure could be devised which would keep all the people in a town of this sort?—I think it is quite impossible.

20,252. (*Dr. Ruffer.*) Was there a sudden running away when evacuation began?—No, I do not think so. We had arranged quarters for the people outside, and they thought they might as well stay. Those who remained behind had probably something to tie them to the place.

20,253. You said you began general evacuation in the beginning of December?—Yes.

20,254. Can you tell me, week by week, how many people had been evacuated in December?—I cannot tell you.

20,255. Can you tell me approximately whether half the number had been evacuated by the 10th of December?—I should think over half.

20,256. Could you tell me the mortality among the evacuated and the people in the town?—I could not tell you.

20,257. Do you think the mortality was larger in the town than in the evacuation camps?—Much larger in the town; it was extremely heavy; while outside there was hardly any.

20,258. (*Mr. Cumine.*) After all the people had been turned out of the town, did you find it possible to prevent them coming into the town during the day on business, or walking through the town?—We allowed anyone who had property of any value in the town to come in from time to time to open his house and see if everything was right, but they had all to be out in the evening. There was no one allowed in at night.

20,259. What did you do with all the shopkeepers?—They were all arranged in streets in the camp. We had a grain street and a cloth street, and so on. They had all their streets outside in the camps.

20,260. Were the people in the health camps free to go about their duties in the day?—Yes, quite free, there was no restriction.

20,261. Could they go into the town?—They could go into the town generally, but we tried to prevent them going in to any great extent, only there was no absolute prohibition. If anyone wanted to go in he was allowed to go to his house and open it.

20,262. There was a great exodus when the plague first appeared. If Sholapur was attacked again do you think there would be the same exodus, or anything approaching it?—I do not think it would be quite so bad.

20,263. When plague appeared in the town of Sholapur, and as it got towards the Nizam's frontier, did you on each occasion let the Resident of Hyderabad know that plague had appeared near his borders?—I do not think we did our duty exactly in that respect; we gave information afterwards. I think the charge against us on that point is just.

20,264. Though you evacuated this large town on that one occasion do you think it a practicable thing to do to go on evacuating it on every future occasion in which plague may get into the town—a large commercial town like that?—It is not a large commercial town, and I think it was that fact that helped us to evacuate

entirely. It is a great grain distributing centre, and this work can, of course, go on outside the town as well as in the town, but it cannot be called a commercial centre, I think.

20,265. Do you think it practicable to go on evacuating each time?—I think it could be done again; I do not know whether it is advisable, but it could be done. The people have got used to being out and they are quite content to be out. There were discomforts, of course, but there were no serious complaints.

20,266. (*The President.*) I judge that you did not regard partial evacuation as successful?—No.

20,267. This partial evacuation was not commenced, I think, until there was already a considerable amount of plague in the town?—No.

20,268. At the time you were partially evacuating, the people were running away?—Yes.

20,269. You had probably no provision made for those who wished to go away, in the neighbourhood?—We had not a large enough camp.

20,270. But supposing you had effected complete evacuation at the commencement, do you think you could have provided accommodation for this large multitude?—It could have been done. The people generally belong to the poorer classes, and can do with very small accommodation in camp. We gave them generally small triangular huts made of bamboo and cloth stretched over. The great majority of the people were housed in these huts.

Mr. W. T. Morison, I.C.S.

21 Feb. 1899.

20,271. Are your measures for detecting cases more perfect now than they were originally?—I have not had any experience of plague work since then.

20,272. In the latter part of your experience had it been improved?—My experience stopped at the end of my time in Sholapur, in January 1898.

20,273. Supposing there was an outbreak again, do you think that the early cases could be more successfully detected than they were before?—I cannot say, I do not think they would. I think that by the end of our campaign at Sholapur we had got everything arranged, and the inhabitants, too, were in more or less training.

20,274. Are you able to tell me whether the cases appeared to be equally severe, or not so severe at the latter part of the epidemic when the numbers were being reduced, compared with what they were at the earlier parts, or when the plague was most prevalent?—They seemed to me equally severe. The average mortality among the number of cases seemed to be as large at the end as at the beginning.

20,275. Therefore, possibly the falling off was not due to diminution in the virulence of the plague itself?—So far as I could say it was not.

(Witness withdrew.)

Mr. N. A. F. Moos called and examined.

20,276. (*The President.*) You are the Director of the Government Observatory at Bombay?—Yes.

Mr. N. A. F. Moos.

20,277. (*Mr. Hewett.*) You have prepared a chart,* have you not?—I have.

20,278. With what object?—In order to see if the mortality curve was in any way influenced by any seasonal factor or combination of factors. My attention was first drawn to it by a letter from Mr. Monteath, the Chief Secretary to Government, who asked me to submit the daily curves of temperature, expecting that these would present some resemblance to the mortality curve. By examination, I found that the vapour pressure curve ran more closely parallel (inversely) to the mortality curve than the heat curve; and it was on those suggestions that I thought that the two factors properly combined might give a resultant curve, fairly coincident with the mortality curve.

20,279. What are the data from which you have prepared the vapour curve?—From Regnault's formula. All the observations were taken at the Kolaba Observatory. From the readings of dry and wet bulb thermometers vapour tension was derived, and from this vapour tension the dew point is obtained from tables, and the dew point then is modified by the difference in the temperature of the air and the temperature of the ground. This would roughly and indirectly measure the ground evaporation, because according to a theory analogous to the theory of exchange in heat, the greater is the amount of vapour in the air, the less would be the evaporation from the ground, and the less the quantity of vapour in air the greater the exaporation from the ground. That which has greater humidity parts with its moisture to the other which has less, and it is on this theory that the tension of moisture in the air would measure indirectly the evaporation from the ground. Unfortunately, in the observatory, no direct observations of the atmometer or evaporometer are available. In the absence of these observations, the only possible approximate way to get the ground evaporation is by combining such factors as measure this evaporation indirectly; and these factors are the dew point, modified by the difference of the temperature of the air and that of the ground.

20,280. Where did you take that temperature?—At the Observatory.

20,281. At what depth below the surface?—Of course there are various depths at which temperatures are taken. For my purpose I have selected five feet below the ground. Temperatures are taken at various depths, from one inch to 12 feet; the maximum depth at which we take the temperature is 12 feet. The reason why I have selected five feet under the ground is this: the diurnal variation due to solar heat at Kolaba does not take effect in the ground beyond a depth of nine inches; the annual variation goes beyond this zone, but does not penetrate beyond a depth of 12 feet; I have therefore selected five feet as not being too shallow nor too deep; and, even taking the observations at other depths, the curve will be more or less analogous to the one which I have shown. Before I arrived at the data I made several trials with different depths and different factors, and the curves were found to be more or less similar. There is a slight difference in the runs, but the reasons of the discrepancies can be easily explained; the general run, however, is almost the same as that submitted in my chart.

20,282. (*Dr. Ruffer.*) Is your method liable to error; what is the percentage of error?—That I really cannot say, but I think that the general run of the curve would not be affected, although possibly the weekly fluctuations might.

20,283. How much do you think it could be affected? Would it be 10 per cent. or one per cent.?—I really cannot answer that question, as in cases of approximation it is difficult to judge exactly; but I do not think it would appreciably differ from the curve submitted.

20,284. Would it be such an error that it would affect your curve much?—No.

20,285. Visibly?—No, not visibly.

20,286. (*Prof. Wright.*) Do you call your curve a climatic curve, or a ground evaporation curve?—Yes, the so-called climatic curve represents approximately a ground evaporation.

20,287. Does your curve express the resultant of four different series of data: one, the temperature of the air; secondly, the temperature of the ground; thirdly, the amount of moisture in the air; and, fourthly, the amount of moisture in the ground? Are all those four factors taken into account?—Yes. The first three would indirectly represent the amount of variation in the ground evaporation.

20,288. I suppose the higher the temperature in the ground the more the moisture, and the greater would be the vapour-tension in the ground?—The greater the tension.

20,289. And in the case of the air I suppose that the less the amount of contained moisture and the higher the temperature, the greater would be the tendency to take up vapour from the ground?—Other factors remaining the same, the less the vapour in the air, and the higher the temperature of the air, the greater will be the tendency for the air to take up moisture from the ground. It is a question of relative tension. If the tension in the air is greater than that in the ground the air would part with its moisture to the ground, and *vice versâ*.

20,290. Your curve, then, represents the balance between the two tensions—the tension of moisture in the air and the tension of moisture in the ground?—

* *See* App. No. LVIII. in this Volume; the charts and notes put in by Mr. Moos are published with notes regarding them made by Dr. A. Buchan, LL.D., F.R.S., Secretary to the Meteorological Society for Scotland.

Mr N. A. F. Moos.

21 Feb. 1899.

Yes, it measures the tension of the vapour in the ground, as determined indirectly from the tension of vapour in air.

20,291. How is the vapour-tension of the ground determined?—I have not been able to determine, as already stated, the absolute amount of moisture in the ground.

20,292. Is there no method by which it can be directly determined?—There is; by observations with atmometers and evaporometers, but we have not got these instruments.

20,293. What do you substitute for them?—By a mathematical reasoning, knowing that the vapour-tension of the air varies inversely as the vapour-tension of the ground, the former, modified to the temperature of ground, would approximately and indirectly measure ground evaporation.

20,294. You mean to say that the tension of air would vary inversely with vapour-tension of the ground if it were freely exchanging vapour with the ground?—Quite so; the theory of exchange in heat may be analogously applied to the moisture too.

20,295. But the air is not freely exchanging vapour with the soil five feet below the surface?—The tension of the vapour in the two are relatively connected.

20,296. Why did you select this depth of five feet? Did you select it because you found the curve that you obtained in this way agreed with the curve of the mortality?—Yes. The average run here is much more close than when the other depths are taken, but the difference only lies in the weekly fluctuations, and not in the general run of the curve.

20,297. You said the seasonable variation ceased to make itself felt at 12 feet below the surface?—Yes.

20,298. You took as the basis of your curve the observation made at five feet below the surface, but I understand that your curve would have come out quite the same if you had employed thermometrical readings which had been taken at other depths below the surface?—Yes. The broad undulations correspond in each case, under certain limits.

20,299. But the small undulations?—They do not quite correspond.

20,300. Then did you choose the readings obtained at a depth of five feet, because the curve which was based upon these readings coincided most closely to the curve of the mortality?—Yes.

20,301. (*The President.*) How do you state the relationship between the surface evaporation, and the mortality rate from plague?—Whenever the ground evaporation was a maximum, the mortality was a maximum.

20,302. You have handed in a written statement here, which embodies all your views. I believe they are all contained in this paper?—Yes (*see* Question No. 20,309).

20,303. (*Prof. Wright.*) You think the mortality is greatest when the ground is giving off most vapour to the air?—Provided it is contaminated, because that is the basis on which I go. Under ordinary circumstances, in normal years, this seasonal increase in ground evaporation would be innocuous.

20,304. Does that mean that the mortality is greatest when the upper surface of the earth is most saturated with moisture?—It goes without saying, because if there is evaporation from the ground, there must be moisture.

20,305. But would the upper surface of the ground be most saturated with moisture whenever vapour was being given off from the ground; are there not two factors which determine the moisture of the surface of the ground: first, the deposition of dew from the air, and secondly, the moisture coming up from below?—I may say that the moisture of the air is mainly derived from the sea, but the moisture of the ground depends on the geological structure, and the environments of the place, as well as local causes: *e.g.*, the water supply, the proximity of lakes or tanks, and the free and profuse use of water, under which circumstances it is possible that the surface to a depth of five to ten feet may be thoroughly saturated with water.

20,306. Would not the moisture of the surface of the ground be more influenced by the deposition of dew than it would by the evaporation of vapour from the ground below?—Not so much; the inherent moisture of the ground would not be affected, specially in the deeper parts of the ground, by the deposition of dew.

20,307. But would not the moisture of the surface of the ground be most influenced by dew being deposited on it?—Just the very surface.

20,308. (*The President.*) As far as I understand, it appears that the more favourable the conditions for the virus to rise from the ground into the air, the greater is the mortality from plague?—Yes.

20,309. Will you put in all these papers, showing the data?—Yes. They are as follows:—

"The object with which the following inquiry was undertaken was to find whether any meteorological factor or combination of factors had any direct or indirect influence on the mortality of the city from week to week and month to month.

"At the outset it was noticed that no very abnormal feature could be detected in the various meteorological factors of the plague years, as compared with those of past years, except in one single factor, that of ground temperature.

"The yearly value of temperature fluctuated irregularly for about 40 years past about 83° Fahr. It, however, began to rise at all depths, feebly but steadily, from the year 1888, and the figures for 1896–97 and 1898 are exceptionally abnormal, *vide* table attached (Temperature of Air and Ground, 1846–98).*

"The first step, therefore, was to see whether any combination of this factor with other factors like air temperature, 'moisture,' &c. could give a curve which in its general run coincided with the mortality curve. After several trials it was seen that temperature of the air, temperature of evaporation, and temperature of ground five feet below the surface, if combined in a certain way, gave a curve which ran strikingly parallel to the mortality curve, and the principal, as well as the subordinate, maxima and minima points of which were coincident.

"The coincidence cannot be a mere accident for such a long period as three years; and it may be presumed, therefore, that some sort of relation does exist between the two as indicated.

"The nearest, though not *absolutely correct physical interpretation*, of the combination of factors adopted, is ground evaporation, and the curve so delineated may be accepted as representing ground evaporation.

"The question of importance in the above comparison is not about the arbitrary selection of a depth of five feet below ground surface, the selection of which will be presently explained; but whether the interpretation of the combination to mean ground evaporation could be justified. It was with a view to examine this point, that combinations were made in several ways by which the nearest approach to ground evaporation could be represented. The ground evaporation may, approximately, be represented by the formula:—

$$F = f - c\,(t_g - t_a) \times \frac{P - f}{3^0}$$

where t_g is the temperature of the ground at any given depth, t_a the temperature of the air, F and f being the tension of vapour at the two temperatures, and P the barometric pressure.

"The curve, however, has been drawn from figures given by $\left[D - (T_g - T_a)\right]$ where D represents the dew point obtained from a similar formula as given above. It may be noted that the curves given by either method are similar and identical. The latter is preferred because the calculations are less troublesome, and give no extra labour, as the factors D and $T_g - T_a$ are daily obtained in the observatory for other purposes.

"The selection of the arbitrary depth, 5 feet, is obvious now from the treatment adopted. In the expression $D - (T_g - T_a)$, if we take the temperature of the ground on the surface, which is almost equal to that of air above, $T_g - T_a = 0$, and the expression becomes D, that is, the curve would represent dew point only. If we go 12 feet below ground, where the temperature is constant throughout the year, and does not vary with solar heat, the fluctuations virtually represent ($D + T_a$ – constant). In both these extreme cases, therefore, the ground temperature will not be represented in the fluctuations of the curve. In order, therefore, to bring the ground factor effectively in the expression, the selection of a depth of 5 feet midway between the two extreme cases was deemed essential. Practically the temperature at 5 feet below ground, therefore, may

* *See* App. No. LVIII. in this Volume.

be taken to represent the integral effect of temperature at various depths from 0 to 12 feet, or the maximum effect.

"In conclusion, I beg expressly to say that I do not assert that the plague mortality, after inception of the germs on the soil, is wholly dependent upon seasonable causes. Obviously that cannot be, as other factors, known and unknown, must also affect the mortality of a great city like this. But I do wish to say that a *primâ facie* case has been made out, to show that the seasonable factor, as measuring ground evaporation, is one of the principal causes which influence the rate of mortality, and which, if conclusively proved, would have an important bearing on the whole question. It therefore justifies further investigation in that direction, and with that view I am strongly of opinion, that thermometric stations should be established in different parts of Bombay, specially in the affected districts like Byculla and Mandvi, &c., to enable ground and air temperatures and absolute evaporation results to be obtained directly, and I have no doubt that important side light would be thrown on the question of propogation of the disease. The indications of temperature, &c., at Kolaba, which is situated on high and rocky ground, cannot exactly measure the important factors under discussion which may be prevalent in the actual plague centres, and, therefore, the proposed stations are absolutely essential in the inquiry."

Mr. N. A. F. Moos.
21 Feb. 1899.

(Witness withdrew.)

Mr. A. G. MACKENZIE called and examined.

Mr. A. G. Mackenzie.

20,310. (*The President.*) You are Superintendent of one of the jails here, I believe?—Yes; I am Superintendent of H.M. Common Prison, Bombay. The information I shall give you will be with regard to the numbers in the prison, the number of those inoculated, and how long they remained afterwards.

20,311. (*Prof. Wright.*) Perhaps you will tell us how the prisoners were selected for inoculation?—I selected them myself. The first inoculation took place on the 1st January, 1898. There were 199 prisoners selected out of a population of 399, leaving 200 uninoculated, about one half.

20,312. On what principles were prisoners selected for inoculation?—On no principle whatever. I formed the prisoners up and selected a few here and there, and formed them into batches. It was an experiment, and half the prisoners were inoculated and the other half were not, and we wanted to see the result.

20,313. Do you think the prisoners who were inoculated differed in any respect from the prisoners who were not inoculated?—Beyond a doubt; I think the inoculated were protected.

20,314. I mean did the inoculated differ in age or physique from the uninoculated?—No, they were formed in a line and I simply took them out here and there. I made no particular choice.

20,315. Were the inoculated persons treated differently from the uninoculated?—No, except that they were sick for 24 or 36 hours, and had to be relieved from their labour.

20,316. During these 24 hours, were the uninoculated exposed to different conditions from the inoculated?—No, I made no difference whatever. They were all placed in their cells.

20,317. What were the results?—The inoculation took place on the 1st of January, 1898. Prior to that there were three cases of plague in the jail, and it was in consequence of that that the prisoners were inoculated. Two of those three cases were attacked on the 31st December, and the third on the day of inoculation, in the early morning, and those three died. After the inoculation there were 17 attacks up to the 29th July, 1898, among the uninoculated. There were only three attacked among the inoculated and they all recovered. Out of the 17 uninoculated, nine died and eight recovered.

20,318. How long were the inoculated and uninoculated under observation? I understand that some of the prisoners obtained their discharge soon after the inoculation had taken place?—My jail may be called a migratory prison; they are all short termers, in to-day and out to-morrow. At the end of July there were about five men left out of the 400; the others had all gone and an entirely new population was in the jail, short-term prisoners, some a few days, some one month, and some two months, and so on, and perhaps a few up to 12 months, say half a dozen.

20,319. Were the numbers of the uninoculated increased by fresh prisoners coming in?—Beyond a doubt, but I am only speaking with regard to the population which was in the jail on the day of inoculation.

20,320. You have confined your statistics to what happened amongst those?—Yes; the other men did not come under my observation; there was no need for it.

20,321. Among the 200 who were uninoculated 17 cases occurred?—Yes, up to July.

20,322. Have you any information about the subsequent fate of those who left the the prison?—None whatever.

20,323. We have had it in evidence that there were two suspicious cases of plague admitted to the Parel Hospital who had been inoculated in your jail. It was doubtful whether these particular patients had mild plague or whether they had mumps; do you know anything about these cases?—No, I do not. I know that three prisoners have been recently attacked, two during January, with plague.

20,324. (*Mr. Ruffer.*) Inoculated or uninoculated?—Uninoculated.

20,325. (*Prof. Wright.*) Have all the inoculated now left your prison?—They have all left except five.

20,326. Can you give us the dates on which the inoculated persons left?—Yes, I can give you the statement, and also a statement showing how long those who were not inoculated were in the prison and when they were discharged.*

20,327. How long did the epidemic of plague last?—Up to the 29th July.

20,328. You mean that there were dropping cases up to this time?—Yes, the 29th July was the last. The cases prior to that were on the 29th June, 18th March, 28th February, 10th February, 2nd February, and so. They were quite sporadic.

20,329. Were any of the prisoners seriously ill after inoculation?—No, they all recovered within 36 hours or so.

20,330. Do you think the amount of reaction which you got in the prisoners was fairly equal?—Some suffered more than others, but all about the same time, from about 24 to 36 hours. Some suffered very acutely, or, at all events, their complaints were greater. They may have been less able to bear the pain, but they appeared to suffer more.

20,331. (*Dr. Ruffer.*) Can you prepare a table giving the name of each prisoner, the age of each prisoner, the date of inoculation, the date of entrance into the jail, the date of exit from the jail, the number of the cell in which he got the attack, the date of the attack, and the result of the attack?—I put in a statement* which gives the particulars required; there is, however, no record of the particular spot where each attack took place. All the cases occurred in the quadrangle on the south side of the prison, the first four attacks being in a spot in the south-west corner of the corner of the barracks—a large barrack where the prisoners sleep in association.

20,332. (*Mr. Cumine.*) To what extent were the attacks among the uninoculated due to the mere accident of their having slept in a cell where there had been a previously infected person? I believe there was some plague in the jail before you performed the inoculations?—Yes, three cases in December.

20,333. Do you know in what cells those three cases lay ill?—Yes; they were all in what we call the lower barracks, not in cells—the barrack is a large building well ventilated.

20,334. With regard to the uninoculated persons who were attacked after the inoculations, could you tell us how many of them slept in that barrack in which the three people slept who were attacked and died before the inoculation?—Yes. To begin with, it is a large

* *See* Appendices Nos. LIX., A. and B., in this Volume.

Mr. A. G. Mackenzie, 21 Feb. 1899.

barrack. They were all three attacked, I think, on the lower floor and in a particular spot. It is a singular fact that attacks took place on the south western side of the barrack more than in any other part of the jail. I cannot account for it because the whole jail is clean and dry, but such is the fact, there were four cases here.

20,335. Had the three persons who had been attacked before the inoculation been sleeping in that spot?—I think I can find that out for you. (Note by witness on correcting proof of his evidence:—I find that they had been, and I then, on the 7th January, turned the whole of the convicts out of the buildings and made them sleep in the open; no case then occurred till the 15th January 1898.)

20,336. When uninoculated persons sleeping in that spot were attacked, were the inoculated persons sleeping there also?—Yes, there was never separation made at all.

20,337. Were they sleeping in that particular part of the barrack?—Yes. The men are shifted about indiscriminately. Prisoners are never allowed to sleep in one particular cell or one particular part of the barrack; that is our system of discipline. If a prisoner were kept in the same spot he could carry out his measures for escaping day after day, and so we shift them about.

20,338. As a fact, can you say that in this particular spot which appeared to be infected there were inoculated as well as uninoculated people sleeping after the inoculations?—Beyond a doubt, but they were all turned out and the building vacated on the 7th January.

20,339. Did you find that the inoculated people sleeping on the spot were attacked?—All the facts are to be obtained from my register. No inoculated man was attacked there; as a matter of fact the place was vacated as I have previously stated seven days after the prisoners were inoculated.

20,340. (*The President.*) When a case occurred, how did you dispose of it?—I sent cases to the Plague Hospital.

20,341. How did you treat the cells?—The cells were disinfected and the clothing destroyed, and no prisoners were allowed to be locked up in that locality for several days—10 or 15 days. I kept those cells as vacant as possible, but, unfortunately, at the time the jail was very much over crowded. The accommodation was for 160 prisoners and we had nearly 400, so it was terribly overcrowded. It is astonishing that the plague did not spread further in the jail, but I believe that the reason it did not was on account of the measures which I took. I burned a tremendous lot of quicklime, put it on boiling all over the place, roof, floors, the whole of the quadrangle and ground, and every corner, and I kept it up for several days. I am of opinion that I prevented it developing into an epidemic and that I destroyed the plague altogether in the jail ultimately.

20,342. I understood you to say that in a certain part of the jail cases did take place?—They were sporadic cases; it could not be called an epidemic.

20,343. Did you each time disinfect that part especially?—Each time.

20,344. How did you disinfect it?—With quicklime in a boiling state and carbolic dilute.

20,345. How was it diluted?—The Medical Officer prepared the prescription and it was mixed accordingly and thrown on.

20,346. Obviously, that part had not been properly disinfected?—I cannot account for it.

(Witness withdrew.)

Mr. C. N. Hall.

Mr. C. N. Hall called and examined.

20,347. (*The President.*) You are Superintendent of Her Majesty's House of Correction, Byculla?—Yes.

20,348. (*Prof. Wright.*) You superintended the inoculations in January 1897?—Yes.

20,349. How many cases of plague were there before inoculations were resorted to?—I cannot give you that information.

20,350. Were you present when prisoners were selected for inoculation?—There was no selection; it was voluntary. The prisoners were asked to come forward if they wished to be inoculated and those who came forward were inoculated.

20,351. How many were inoculated?—153.

20,352. How many were left uninoculated?—185.

20,353. Were these prisoners all in contact with each other after inoculation?—Yes.

20,354. Did the prisoners who were inoculated differ in any way from the uninoculated in age or health?—They were about the same.

20,355. Did they follow different occupations?—No, all one occupation, *i.e* intra-mural industries.

20,356. How do you know how many cases occurred among the inoculated and among the uninoculated?—I can give you that information, but I may mention that the Assistant Surgeon of that prison is here, and he will give you all information. The inoculated and uninoculated were all treated in the same way. There was one point of difference, viz.: that those who were inoculated did not work the next day. They said the fever was so great that they could not work, and they were excused. There was no difference in diet or anything else.

20,357. Were the uninoculated kept in a part of the jail where the plague had occurred before near the original plague cases?—No. After the plague occurred inoculated and uninoculated were all moved into work sheds; the whole body of prisoners was taken out of the cells.

20,358. (*Dr. Ruffer.*) Could you put in a table showing on which day the plague began, the names and ages of all prisoners, the date of entrance in the jail, the date of inoculation, the date of discharge, and the date of attack and the result?—This is with Mr. King's evidence.*

* *See* App. No. LX. in this Volume.

(Witness withdrew.)

Assist.-Surg. A. King.

Assistant Surgeon A. King called and examined.

20,359. (*The President.*) Are you the Assistant Surgeon of Her Majesty's House of Correction, Byculla?—Yes.

20,360. (*Prof. Wright*) Can you give us any facts about the inoculations which were done in the Byculla Jail in January 1897?—Yes.

20,361. Were you present when the prisoners were selected for inoculation?—Yes.

20,362. Is it your opinion there was no difference between those who were inoculated and those left uninoculated?—There was no difference at all.

20,363. And is it your opinion that the inoculated and the uninoculated were treated in exactly the same way afterwards?—Exactly, except that they did not do any work the next day or so.

20,364. Did any of the prisoners suffer severely from the inoculations?—Yes; a number of them suffered very severely.

20,365. Were there any among the inoculated who did not react to the inoculations?—Yes; they had no fever after the inoculation.

20,366. Can you trace whether the inoculated who subsequently got plague had or had not a severe reaction at the time of inoculation?—There were five men attacked with plague after inoculation out of which three died. Of those who recovered one had been inoculated once and the other had been inoculated twice.

20,367. Did all these five occur within a few days after the inoculation?—The inoculation was done at 3·30 in the evening of the 30th. Three of them got plague about six or seven o'clock the same evening. One case occurred on the 1st February and the other on the 6th February.

20,368. Then there was an interval in two cases between the inoculation fever and the attack of plague?—Yes.

20,369. Can you find out in those cases whether the inoculation fever was high or whether it was very insignificant?—In one case Dr. Haffkine thought it was the reaction fever, that is, the one which occurred on the 1st February, but the other case he thought was plague.

20,370. Had the inoculation fever been high or insignificant in the second case?—It was 102 or 103—the man had glandular swelling.

20,371. Do you mean he had glandular swellings when attacked with plague or after inoculation?—I think glandular swellings due to plague symptoms, not after the inoculation.

20,372. What interval was there between that man's inoculation and the attack of plague?—The first inoculation was done on the 30th January, and the second on the 2nd February; he got plague on the 6th February.

20,373. He had been twice inoculated?—Yes.

20,374. I suppose that the temperature which he had on the 3rd was due to his inoculation?—Yes.

20,375. Do you know how high the temperature was?—100·8.

20,376. Can you tell us what was his temperature after his first inoculation?—No, because I had been inoculated and was seedy myself at the time.

20,377. Will you look through the records and ascertain whether you have any data to enable us to decide whether the prisoners who reacted were absolutely protected, and whether there was a defect in reaction in those prisoners afterwards attacked with plague, stating also the dates on which the inoculated prisoners left the House of Correction?—I can give you a very accurate statement with regard to the second inoculation, done in 1898, but with regard to the first I am afraid I shall not be able to give you the data exactly, because I was inoculated and prevented from doing my work.*

20,378. (*Dr. Ruffer.*) Were the same prisoners present at the second inoculation as were present at the first?—A few of them.

20,379. Where were the buboes situated in the three cases inoculated by M. Haffkine, which were classed as having plague when inoculated?—Prisoner, No. 672, Keshav Umishankar, left inguinal and femoral glands. Prisoner No. 1356, Abdool Karim Goolam Hussain, left axillary glands, subsequently the whole lymphatic chain, as far as the wrist, was swollen and painful, including the left mammary. Prisoner, No. 1222, Govind Pandu, left axillary glands.

Assist.-Surg A. King.

21 Feb. 1899.

20,380. Can you give us ages of all prisoners attacked?—Yes.

No.	Prisoner's No.	Name.	Years of Age

(Witness withdrew.)

Major H. P. Dimmock, I.M.S., called and examined.

Major H. P. Dimmock, I.M.S.

20,381. (*The President.*) You are a Doctor of Medicine of Durham University?—Yes.

20,382. And you are in the Indian Medical Service, and have had a large experience of plague in Bombay?—Yes.

20,383. I understand you were a member of the Plague Committee?—Yes; I was appointed in March 1897.

20,384. Will you give us your views as to how the bacillus produces plague?—By entry, primarily, I think, through the distal lymphatics.

20,385. What form does it generally produce then?—The bubonic is the most common, of course the development of buboes through the infection of the distal lymphatics.

20,386. The bacillus may infect through other channels, may it not?—Yes. I think it may effect entry through the mucous membrane, and probably through open sores of the skin, and also through the lungs.

20,387. What part of the gastro-intestinal canal do you think the bacillus enters?—I think it may be passed through the mouth and also, possibly, through the anus, because the natives use ablutions to a considerable extent, and it is possible that if there is any excoriation about the mucous membrance of the anus, infection of the lymphatics may take place in that region.

20,388. With regard to mouth infection, do you think the absorption takes place actually through the mouth surface?—I think so, in some cases. It is difficult to explain how it is that one gets infection of the glands in that region. Then there is the abdominal type of the disease, which must necessarily, I think, be the result of infection directly through the gastro-intestinal canal.

20,389. How is it introduced into the gastro-intestinal canal?—I suppose it is swallowed with food or liquid.

20,390. Have you any knowledge of the influence of the gastric juice upon the bacillus entering in that way?—Not from bacteriological knowledge.

20,391. From any source of knowledge?—I could not say that I have made any practical experiments with regard to the gastric juice.

20,392. What led you to say that it may be passed down as far as the stomach and be absorbed through the gastro-intestinal canal?—Simply from my clinical experience.

20,393. Of what kind?—Inference from the method of development of other diseases, such as typhoid fever and the general symptoms of the abdominal type, there being no evidence to show how the bacillus can have penetrated the system except through the intestinal canal.

20,394. I think you have seen some cases where you suspected that the nasal mucous membrane was the absorbing surface?—I had a very interesting experience before I was placed on the Plague Committee. A group of Parsees came in from Thana, and the children were

Major H. P. Dimmock, I.M.S.

21 Feb. 1899.

suffering from nasal catarrh of a most severe type. The symptoms were, apparently, very acute—coryza, with a high temperature. There was no glandular enlargement in the early stages, but, subsequently, the mucous membrane of the nose and of the pharynx swelled up to a tremendous degree. Eventually, the lymphoid tissue became infected in the same way and the patient apparently died rather suddenly, of suffocation. Within three or four days—in the severe cases—I took three of the children to Professor Haffkine's laboratory, and he investigated the cases most carefully, and finally decided that he could find no evidence of their being plague. At first I thought they were some peculiar cases of diphtheria, but diphtheria is not very common. It does occur during the rainy season, but even then it is not very common. The cases then passed out of my sight—they came to the out-patient department of my hospital and passed out of my sight and went to reside in Mazagaon. From the Health Officer, Dr. Weir, I understand that they set up a very severe epidemic in that region, that they were a focus of a severe epidemic of plague in Mazagaon.

20,395. How many cases did you see?—I saw four.

20,396. In one family?—Yes.

20,397. Did you trace the source of infection?—They came from Thana.

20,398. Was there plague there at that time?—Yes.

20,399. Have you any evidence of any direct contact or relationship?—There were other similar cases occurring in the same house and also cases of plague.

20,400. The important point appears to be that these cases communicated plague to some others?—Yes, and they came from a plague infected centre.

20,401. I think you said that Professor Haffkine did not find the plague bacillus?—He found no plague bacillus. He investigated the blood and the discharge from the nose.

20,402. Have you observed any cases in which direct inoculation of plague could be proved?—We have had one case in which we could positively say there was inoculation, and that was one of the Roman Catholic Sisters at the Parel Hospital, Sister Elizabeth. Her's was evidently a case of auto-inoculation through a pimple or small boil; there was pain and swelling in the region of the boil. In other cases I have seen bullæ formed evidently at the site of inoculation.

20,403. Why evidently?—Because the general symptoms of plague developed afterwards, and because the glands in connection with the distal lymphatics of that region were inoculated.

20,404. From the cases which you have observed, will you give us the usual symptoms of plague?—The symtoms, of course, depend upon the region of inoculation. Where it is through the lymphatic system we get the bubonic form, which is the most common, of course. There are statistics in the two reports* of the Plague Committee, giving the proportions of the bubonic cases in the various hospitals. Some have a greater proportion than others. Then there is the infection direct into the blood-stream, the septicæmic form. These cases are not so frequent, but it is evident that they do occur, because cases have been met with, and I have seen them myself in the hospitals, in which the symptoms are those of general sapræmia. In fact, I think, all these classes of the disease very closely resemble septicæmia, as we understand it, both in the pathology and development of the symptoms. Then there is the other infection through the lungs which produces a distinct form of lobular pneumonia. The first case which came under my notice was the late Dr. Manser, whom I attended in association with Dr. Childe.

20,405. In what respect is it a distinct form of lobular pneumonia?—I mean it is unusual to find lobular pneumonia occurring primarily in a healthy adult. The lobules could be percussed out.

20,406. What is the character of the sputum?—It is sanguineous, of a peculiarly watery consistence, and contains a pure culture of bacillus. You simply have to stain it and put it under the microscope and you can see crowds of the bacillus quite plainly.

20,407. Now with regard to the symptoms?—I have mentioned the following in my précis of evidence:—(*a.*) Pyrexia, 103° to 107° by third day. Toxæmia more marked, with onset of pyrexia. Glands early enlarged, acutely tender, painful, (femoral, inguinal, cervical, axillary). Great nervous prostration in many cases. Pulse soft, quick, small, compressible. Delirium often violent. Vomiting, sometimes severe; silvery tongue characteristic; constipation. Dusky congestion of skin and conjunctivæ; appearance of face characteristic. Lethargy. Death usually sudden from syncope; cases vary in severity; fatal in about five days; recovery by long convalescence. Later cellulitis around glands and suppuration in a large proportion. (*b.*) Pyrexia high; rapid asthenia fatal in a few hours up to two days; always fatal. (*c.*) Lobular pneumonia; pyrexia not very high; toxæmia marked; rapid asthenia. (*d.*) Choleraic form.—No pyrexia; extreme collapse: diarrhœa; no cramps; death in a few hours. Peritonitic form.—Great and early distension of abdomen; dusky appearance; marked toxæmia and asthenia rapid and marked. Both forms always fatal. Direct infection of lymphatics in majority of cases; development of toxine in glands and discharge of same into blood; bacilli frequently not detected in blood. In septicæmic form organisms pass directly into blood; toxines and bacilli develop in great intensity. In pneumonic form toxines manufactured in air cells and absorbed by capillaries and lymphatics.

20,408. What do you say about hospital mortality?—The general mortality was 65 per cent. I take that from the general results of our report. In cases without buboes the mortality was about 75 per cent., and in treated cases 41 per cent.

20,409. I suppose that has come under your own observation?—As an administrative officer I simply observed the general results of the hospital. I was constantly going through the hospital.

20,410. This is one out of a great number of similar statements in that† report?—Yes; it is one large Plague Hospital.

20,411. Then it does not show generally what the hospital mortality is?—I have taken it—the figures of the hospital—as representative of the general mortality.

20,412. Will you give us your views as to the method of infection?—It is by direct infection of the lymphatics in the majority of cases, generally from a plague patient. In the large proportion of cases, I think, human beings are the carriers of the disease to human beings. In certain instances, there is no doubt that rats will communicate the disease, and diseased rats may possibly start an epidemic. I am almost inclined to think that rats were the original cause of the epidemic in Bombay. I have a letter from a large firm, Messrs. Ralli Brothers, dated 11th September, 1896. It is a report to the Health Officer of the Bombay Municipality. They state that they had 13 fatal cases of fever among their native employés and coolies who were working in the godowns at the Ryan Market, Frere Road, which is close to the docks. That was on the 11th September, 1896. There was evidence of plague previous to that.

20,413. How does that bear upon the introduction of plague into Bombay?—It is an inference from those cases. Before those coolies were attacked, large numbers of rats were found dead in the go downs.

20,414. That was in September?—Yes.

20,415. But plague began here in July; therefore, this does not bear upon the introduction of plague?—It is merely an inference.

20,416. What definite evidence have you that rats may convey the plague?—I have given a few examples in my précis. Frequently cases of plague developed in houses, and when the houses were searched dead rats were found. In another instance from those quoted in the précis, in a house in the Fort the residents reported that rats were dying in the house. We recommended them to evacuate that house and have it thoroughly overhauled. They were Europeans and they did not do so. A few days afterwards some of the servants were attacked with the plague, and a few days after that one or two of the Europeans were attacked with plague.

20,417. Can you exclude human conveyance in that case?—No.

* *See* Appendices Nos. XIII. and XIV. in Vol. I. of the Commission's Proceedings.

† "Report on the Bubonic Plague in Bombay, 1896–97:" by Brigadier-General W. F. Gatacre, C.B., D.S.O., Chairman of the Plague Committee.

20,418. Have you anything which absolutely shows that rats communicate or convey the disease?—The only definite case is that of the servant boy, a Goanese who removed a dead rat from the floor and burnt it; he was attacked with plague four days afterwards.

20,419. Might he not also have come in contact with a human subject?—Yes, he might.

20,420. Have you anything more definite?—No; one has nothing really definite.

20,421. So far as human conduction is concerned, what are the most favourable conditions for it?—Overcrowding in the small insanitary rooms in which the natives live. That is the primary cause, I think.

20,422. Did the people suffer most who lived on the ground floor or who lived on the upper floor?—On the ground floor.

20,423. Do you know whether any other animals besides rats may be infected with plague?—Cats have been found to be affected.

20,424. What was the evidence with regard to cats?—Dr. Sticker found the bacillus in cats. The cats were found suffering in the Phatak Wadi (Market Section). They were sent to Professor Sticker who found the plague bacilli.

20,425. What were the symptoms of plague in those cats?—The cervical glands are mostly affected; they are enormously swollen. There is œdema in the mucous membrane of the mouth, the throat, the pharynx, and they died of suffocation. They probably got it from killing infected rats.

20,426. Have you known other animals to be affected?—I have not met with instances of any other animals.

20,427. How long do you think a patient who has recovered from plague may remain a source of danger?—That has always been a very difficult point with me. When we were working on the Plague Committee it was a very important consideration so far as I was concerned, with regard to convalescent patients. I considered six weeks or two months ought to elapse before the plague patient was allowed to mix with people, but I have never been able to obtain evidence—although I have tried—as to whether convalescents would give rise to infection.

20,428. It is pure supposition?—I will not say it is supposition; I could not say it has not actually occurred.

20,429. Can you say it has?—I cannot say it has, but I should think it must be probable; they may be compared to contacts, and should, therefore, be segregated for a certain time. I am inclined to think that some epidemics at a distance, which have been hitherto unexplained, may have originated from convalescents.

20,430. What are your views as to disinfection?—I think it is effective if it is possible to carry it out entirely. If an infected room is thoroughly disinfected, I think that you may certainly be able to dispel the disease.

20,431. Have you any cases in which a room thoroughly disinfected has been reoccupied and plague occurred afterwards in that room or in that house?—There was an epidemic in Koli Wadi. The total number of attacks was 16 from February 21st to February 29th 1898. On the 17th March the whole of Koli Wadi was vacated.

20,432. Is that a locality?—Yes, a collection of houses where the fishermen live. A Koli is a fisherman. The evicts were sent to the Wari Bandar Camp for 10 days, and the whole of the district was then thoroughly disinfected and the roofs all opened out. There was no case afterwards for six months, although it was reoccupied.

20,433. How long after evacuation was it reoccupied?—It was reoccupied after 10 days.

20,434. There were several things done here; can you distinguish chemical disinfection and disinfection by the mere access of air and light? Have you any instances in which mere chemical disinfection was resorted to?—In houses with stone floors it has been noted. One Parsee chawl, Lalbag in Parel, was thoroughly disinfected by chemical disinfection. It was a good chawl with stone floors. The people reoccupied it under the same conditions that they had occupied it before and the disease did not occur.

20,435. What disinfectant was used?—Perchloride of mercury, one in 1,000.

20,436. How many cases of plague had there been in the chawl before?—I do not remember the exact figures.

20,437. Do you recollect whether it was a large or a small number?—I suppose about eight or 10 out of about 300 people.

20,438. Each chawl is a separate building, I suppose?—Yes.

20,439. Have you any instances in which houses or rooms have become reinfected after disinfection?—I am afraid a considerable number of the houses were reinfected.

20,440. Have you any evidence in which evacuation of houses appears to have been beneficial?—We have had many instances where evacuation has stopped plague.

20,441. Which of these measures which we have been talking about appears to be most effective in your experience?—I think there is nothing so effective as evacuation. Its effect is immediate, as I think I have shown by the statistics of the Wari Bandar contacts.

20,442. Perhaps you will put that statement in?—Yes, it is as follows:—

STATISTICS of the WARI BANDAR CONTACT SEGREGATION CAMP relating to the period from 1st January 1898 to 30th April 1898:

Total number of contacts admitted	5,790
Average daily admission	48·25
Average weekly population	2196·1
Average daily population	313·7
Maximum number of contacts in camp, on 5th March 1898	1,060
Total number of cases that developed plague	148
Percentage of plague cases over the number admitted	2·55

Out of these 148 cases of plague—

there developed symptoms on the day of admission			46
,,	,,	1st ,, after ,,	35
,,	,,	2nd ,, ,, ,,	19
,,	,,	3rd ,, ,, ,,	16
,,	,,	4th ,, ,, ,,	11
,,	,,	5th ,, ,, ,,	10
,,	,,	6th ,, ,, ,,	7
R.C. ,,	,,	7th ,, ,, ,,	1
R.C. ,,	,,	9th ,, ,, ,,	1
R.C. ,,	,,	12th ,, ,, ,,	2
		Total	148

The cases marked as "R. C." were amongst the re-contacts. They were in contact with a plague case occurring in the camp and were segregated for a fresh period of seven days. The period of segregation was at first 14 days, then ten days, and finally seven days, except in the cases of re-contacts.

20,443. Were you occupied in plague work here at the commencement of the epidemic?—Not altogether from the commencement, but I saw a good deal of it in the commencement.

20,444. Until what time?—I was on the Plague Committee from the 3rd March 1897 to the 7th May 1898.

20,445. Can you tell us what measures were adopted at the outset of the epidemic?—Only from hearsay. I was not associated with them.

20,446. What were the measures adopted during the time you were a member of the Plague Committee?—Segregation of the sick out of their dwelling-houses, removal of all persons from the room in which the patient was seized or had been lying sick, evacuation of the whole house if possible, destruction of the clothing, bedding, etc., which had been in use by the patient, thorough disinfection of the house, thorough cleansing and flushing of all privies and bathing places, and removal of all portions of the roof where such obstructed the sunlight and air entering the dwelling. The prevention of overcrowding was also considered of great importance. In the Second Committee, under Sir James Campbell, we modified those measures by establishing contact camps. The people who had been in absolute contact with the patients were segregated in a separate camp. These measures, I believe, are now adopted all over India; they were worked out originally by the Bombay Plague Committee.

20,447. They have been very successful?—Yes.

Major H. P. Dimmock, I.M.S.

21 Feb. 1899.

20,448. What do you consider is the period of segregation?—I think, from the contact camp statistics, eight days at the outside. This seems a justifiable period from the figures. A comparison between the conditions of the people in camp and in their houses indicates the probably much greater infectiveness of the latter—confirms the opinion of the greater danger of plague-stricken human beings to others—illustrates how the epidemics spread—and helps to justify the measures adopted. I think the contact camp statistics are most reliable, because the contacts are persons who are most liable to infection, and they are the most likely people to give infection. I think that statistics from contact camps will cover all cases.

20,449. How do you account for the fact that plague stops when people are removed to segregation or contact camps or to hospitals as contrasted with the progress of plague when they are left in their own houses?—I think you have a barrier of fresh air between each person. The bacillus can only extend within a certain radius, and can only live under certain conditions such as darkness, dampness, and moist atmosphere. If you remove the people from the vicinity of such conditions you prevent them from becoming infected.

20,450. You have had a good deal of experience with regard to camps?—Yes.

20,451. You give the details of a considerable number in the supplement of the précis which you have handed in?—Yes. They are as follows:—

Camp.	Admissions.	Plague Cases.
Narel Wadi	16,385	40
Modikábna	24.330	64
Wári Bandar	23,542	90
Byculla	14,400	—
Dádar	1,017	2
Byculla Bridge	400	8
Narel Wádi Health Camp	924	6
Kennedy Sea Face	964	5
Goculdas Tejpal	1,560	12
Elphinstone	1,500	—
Cruickshank	192	—
Elphinstone Bridge	783	3
Ellapa Ballaram	1,447	16
Mahratta	1,839	31
Total	88,723	277

These figures further confirm the opinion—(1) That a very small proportion of plague cases occur amongst people in camp, even when these are from the most heavily infected parts of the city, as evicts certainly are. (2) That a very large population was passed through camp in a very short space of time and on the basis of (1) this alone must have had a great and inestimable effect upon the epidemic. (3) That even in Bombay, with the greatest difficulties in the whole of India to contend with in such a scheme, the camp system can be carried out for a great part of the year with advantage. (4) That the camp system is the basis of all plague operations and that it is the only procedure which has an immediate benefit, for plague disappears amongst new arrivals into camp within a week, *i.e.*, if primary cases in camp are properly dealt with. (5) That the incidence of plague at one time falls with greatest severity upon sections of the population, and that these sections vary in the extent to which they suffer according to the degree of overcrowding and the nature of the houses. The method of combatting plague in a large city must be by attacking sections of the greatest plague incidence. (6) That the small proportion of plague cases amongst detentions indicates that where no detention exists, the influx of persons from an infected to a non-infected city brings only a small proportionate number of plague cases, but that, from these lying *perdu* in the the slums, an overwhelming epidemic will arise within two months unless prompt and severe means are taken. This, consequently, establishes the absolute necessity of strict detention, and, further, confirms the opinion of the great danger of infected human beings as carriers of plague.

20,452. You have had some experience with regard to inoculation?—Yes.

20,453. What are the data on which your views with regard to inoculation are founded?—My views are based on actual experience of 149 cases. When M. Haffkine first came to Bombay I saw a good deal of his work in the laboratory and I assisted him occasionally in doing his inoculations, and I have had conversations with him and have a general conviction as to the scientific value of his inoculation.

20,454. Will you give me the data?—One hundred and forty-nine cases were inoculated. There had been 12 deaths from plague among various households before inoculation. After inoculation there were four attacks of plague: two died and two recovered.

20,455. Did you observe these cases which you inoculated for some period of time?—I have the evidence for the whole year.

20,456. Are these figures borne out by the after-history?—Yes; I have enquired about them myself.

20,457. Have you seen any evil effects following inoculation? Do you adhere to your statement with regard to that?—Yes.

20,458. Will you put that statement in?—Yes. The possible evil effects are (*a*) Initiates disease by putrescence, only through careless manipulation, *e.g.*, cellulitis, septicæmia. (*b*) Initiates disease by entrance of the minute particles of débris into the circulation, which would give rise to endocarditis embolic. I have met with one case which gave rise to this suspicion. A Pársee girl, aged about 14, became ill after inoculation, and died two months later. I saw her a few days before death and found her suffering from endocarditis. I have discussed the case freely with M. Haffkine and asked him if the fluid could be filtered in view of this danger. The history of the case throws doubt on the contention that the endocarditis actually resulted from inoculation. She had suffered from fever before, the family have a rheumatic tendency, and I have recently seen a brother of her's, aged nine, who has an irritable heart attributed to over-exertion. M. Haffkine's reply to my question was as follows:—"The solid part in the plague prophylactic is a very "essential ingredient and cannot be filtered off. You "will see that at once when I say that the anticholera "vaccine contains only the solid part and that the "chief modification in the plague prophylactic was the "addition of the liquid portion. The above informa-"tion will also allay, I trust, the apprehension with "regard to the danger of those solid bodies. For if, "in the inoculation against plague, we did, by now, "tens of thousands of operations, P. being the only "patient about whom the question was raised,—in the "inoculation against cholera the number of operations "counts by hundreds of thousands, without my "having heard of the complication now in question." (*c*) Excites latent disease to active manifestation, *e.g.*, rheumatism, phthisis, neuritis, hepatic congestion, albuminuria. I have no authentic data of this. I have met with cases of rheumatism and neuritis which have occurred shortly after inoculation and were attributed to it, but I could not say that the inoculation caused the complaints. There was one remarkable case of a dhobi in Byculla, found during a house visitation and apparently very ill. He had acute pain in the side, and the search party thought he was a case of plague. He had fever. He had been inoculated a few days before. I found it to be simply a case of acute neuritis of the intercostal thoracic nerves. (*d*) Produces varying degrees of impaired health subsequently and for varying periods. Many persons have complained of this, but as a rule it does not last longer than ten days. My own máli was ill for months afterwards with gastric irritability and great depression. Most of the persons I inoculated were able to go about their work in three days without inconvenience.

20,459. You have made frequent observations at five intervals in many of these cases which you inoculated?—Yes. All my own servants were inoculated.

20,460. What symptoms did you observe to follow inoculation?—Pain and swelling of varying degree at the site of inoculation. A preceding period of depression, nausea and sometimes diarrhœa, with pains in the muscles and in the joint if the subject has a tendency to rheumatism. A stage of reaction when the temperature rises to 102° or 103°. In some cases the depression continues and a sub-normal temperature is registered with no pyrexia. The depression lasts for 12 or 24 hours or in some cases longer, and appears in about 12 or 16 hours after inoculation. There may be acute gastric and intestinal irritation. A stage of

subsidence, marked by a fall of temperature, free action of the skin and somewhat depressed state of health, may last for a day or two longer.

20,461. What is your view about the duration of the immunity?—I believe the duration of the immunity lasts a considerable time, and if fully carried out I do not see why it should not be for a life-time. As in the case of other infectious diseases complete immunity is not obtained but general comparative immunity. A person may contract plague after inoculation, but this is in a much redued probability, and if contracted, the disease is not so likely to be fatal. I have no authentic data, but I consider the statistics published by M. Haffkine fully reliable, and they support this view. I do not see why it should not be for a lifetime provided the person is thoroughly inoculated.

20,462. Why do you say that?—I think it is possible it might be.

20,463. One might equally say it is possible it might not be. Have you any facts to lead you to any conclusion as to the duration of the immunity produced by inoculation?—In one or two households which I inoculated the servants have been free from plague up to the present time.

20,464. To what length of time do you refer?—In my own household, during the last epidemic, the wife of one of the servants contracted the disease. She had never been inoculated. Her husband and his brother, who had been inoculated the previous year, were in constant attendance on the girl and never contracted the disease. They went to the Parel Hospital with her and were attendants on her there.

20,465. The immunity lasted one year, you think?—Yes.

20,466. Is it usual for persons who go to hospital and attend on sick persons to contract the plague?—No; but before they went to the hospital the girl had been suffering for two days. It was not reported to me, so that they were in close association with her for two days.

20,467. Are the hygienic conditions bad in your servants' quarters?—No.

20,468. I presume they are good?—Yes.

20,469. Is it usual for plague to extend in good hygienic circumstances?—It is not usual, of course.

20,470. I assume that that house is in a good hygienic condition with regard to ventilation and light?—Yes, very good.

20,471. Have you seen any cases in which after inoculation with an ordinary dose of the fluid the temperature of reaction appeared to be very slight?—I saw a good many of those when I was inoculating for Professor Haffkine in the Grant Medical College. A good number of the cases came and said they had no fever, but felt very depressed, and their temperature had been sub-normal. They were intelligent people and had taken their temperature, and in some cases it was 97—sub-normal. They said the skin had been moist, and they had felt a good deal depressed, but there had been no febrile reaction.

20,472. Have you any evidence that there was an immunity conferred upon those persons?—No, I cannot say that.

20,473. Did the same sample of fluid produce a marked temperature reaction in other persons?—Yes.

20,474. (*Mr. Hewett.*) Have you found that in the quarters of Bombay which have good hygienic conditions the plague has not spread?—The Europeans and their native servants living on Malabar Hill lived under the very best hygienic surroundings, but yet the servants were attacked there and the epidemic spread all through the servants' houses, although very few Europeans were attacked.

20,475. Your servants were under the same conditions as the other servants on Malabar Hill?—I think so, practically.

20,476. Therefore, they were just as liable to attack?—Yes.

20,477. And the servants, generally, on Malabar Hill did not escape?—That is so; the disease spread from one end of Malabar Hill to the other.

20,478. Although the Europeans living in the same compound escaped?—Yes.

20,479. (*Dr. Ruffer.*) What do you mean by the abdominal type of the disease?—Evident symptoms of plague from the general clinical appearances, associated with great distension of the abdomen.

Major H. P. Dimmock, I.M.S.

21 Feb. 1899.

20,480. What sign of plague was there in those patients? Had they buboes?—No.

20,481. How do you know they had plague?—From association with other plague cases.

20,482. Did you ever find the plague bacillus in any of those abdominal cases, or did you simply base your diagnosis of plague upon the fact that they were in contact with other cases?—I based my diagnosis principally on my familiarity with the general clinical aspects of the disease.

20,483. What were the clinical symptoms which led you to diagnose those cases as cases of plague?—The rapid onset of the disease, the high temperature, and the peculiar appearance of the patients, the congested eyes, and the facial aspect, the condition of the tongue and such like clinical symptoms. These were associated with very rapid development of abdominal distension.

20,484. Had they any buboes in the abdomen?—That I cannot say. We were not allowed to make a *post-mortem*.

20,485. Had they any intestinal catarrh or diarrhœa or anything of that sort?—No; there was no diarrhœa.

20,486. Did you examine the intestine after death?—No.

20,487. You made no bacteriological examination of any of those cases?—No.

20,488. You said that Sister Elizabeth had a pimple and got plague: where was that pimple?—It was near the groin.

20,489. How could she inoculate herself there? By scratching?—Yes; I think it was a mosquito bite, but I am not exactly sure. It was near the thigh.

20,490. What sort of pimple was it,—an acne pimple?—It was an insect bite, I think.

20,491. Were you able to trace any lymphangitis from that pimple to the next gland?—Yes.

20,492. Where was the next gland?—Above the groin.

20,493. The pimple was below the groin?—Yes.

20,494. Did she die?—Yes.

20,495. How long was the incubation period in her case?—I think four days.

20,496. You are not sure?—No.

20,497. Do you generally find the lymphatics leading from the point of inoculation to the next gland are enlarged? Supposing you get a bulla on the dorsum of the foot, do you find the lymphatics leading from that to the popliteal space or the groin are enlarged?—Yes.

20,498. Is that the rule?—It certainly was in the earlier cases I saw.

20,499. Are you in charge of any hospital now?—Yes, but not of any Plague Hospital.

20,500. In your précis you say "Tara Naikand's "Wadi in Dhobi Talao—house opened up; no disinfec- "tion, people suffered severely." Can you give us any details about that case?—I am afraid I cannot give you that.

20,501. You mean to say there was no disinfection, but the house was opened up and that people afterwards suffered severely from plague; is that it?—Yes. I remember the case, but I cannot give you the particulars. The house was opened up and there was no disinfection; I cannot remember exactly the reason why it was not done.

20,502. The people went back to their houses?—No; they were not moved out at all; the house was simply opened up waiting for disinfection, and then the disease still continued.

20,503. They were left in the house?—Yes.

20,504. (*The President.*) What does "opening up" mean?—The roof was taken off, the windows and partitions knocked down, and so on.

20,505. (*Dr. Ruffer.*) Can you state the conditions which influence the development of the bacillus outside the body, whether heat, moisture, and so on, will influence its vitality? How do you think the bacillus

Major H. P. Dimmock, I.M.S.

21 Feb. 1899.

lives outside the body? What has it to live on?—In these little rooms, of course, the people spit on the floor, and they are very insanitary. Besides that, the floors are generally of cow-dung, which is rich in organic matter. The people themselves are, of course, also insanitary.

20,506. But how can it develop on the floor in saliva or in cow-dung? Supposing you take a tube of agar, which is a good nutritive substance, and plant the bacillus in one spot, does it spread from that spot? Does it not remain localised to that spot?—I suppose the bacillus must develop within the radius of a plague patient somehow or other.

20,507. What evidence have you to show that the bacillus develops or spreads from the excreta or in any other way?—One has not any actual evidence. I have never heard of anybody who had.

20,508. What excretions, do you think, are most infectious?—The saliva in pneumonic cases.

20,509. Do you think any other excretions are infectious?—I think the excretions of the mouth and nose are infectious. The excretions from the nose were most virulent in the case I have quoted. I am also inclined to think that fæces are infectious.

20,510. Why do you think so? Have you any facts bearing on it?—No, I have not.

20,511. When were the inoculations done at Malabar Hill?—In February 1897.

20,512. How long did you have those servants under observation afterwards?—My own have been with me all the time up to the present.

20,513. There were 149 of them; how long have you had the others who were not your own servants under your observations?—A good many of them are under observation. I always go and visit at the people's houses.

20,514. How many servants have you of your own who have been inoculated?—I think about 12.

29,515. How many of these 149 do you think you have seen since inoculation?—Eighty; that is, about one-half.

20,516. Have you seen any cases of *pestis minor*?—I am seeing them now.

20,517. We should very much like to see one; we have been trying to find them?—I saw them in the beginning of the epidemic of 1896 in the out-patient department of the Jamsetji Hospital.

20,518. What are their symptoms?—Principally mild fever, with slight enlargement of the glands, which passes away in three days.

20,519. Which glands are enlarged?—The cervical glands.

20,520. Why do you think they were cases of plague?—I thought *pestis minor* because I could not explain them in any other way. I have seen two or three cases lately.

20,521. (*The President.*) How long ago?—Within the last month.

20,522. Can you produce any?—I will do so if I can.

20,523. (*Dr. Ruffer.*) In one of the supplements to the précis of your evidence, you mention cases of re-occurrence of plague. Can you give us the facts relating to Dr. Daver's case?—I have not the facts.

20,524. Did you see the Customs clerk who was supposed to have suffered twice from plague?—No.

20,525. You mention a man who had the plague three times; Narayan Muljee: are you satisfied he did have it three times?—I am satisfied he had plague once. I do not see any reason to doubt that he had plague three times from the general description. I quoted them because I was convinced the history was sufficient.

20,526. You say there were two cases of recurrence of plague; what was the other?—They are quoted on page 151 of General Gatacre's report.*

20,527. Did that come under your own observation? They are reported to me.

20,528. Did you enquire into them yourself?—I saw one of them.

20,529. In the same supplement you mention the case of Mr. Lalla, who was inoculated twice and contracted plague and died. You also say:—"The "following evidence is in favour of the theory of "immunity; 15 All Saints Sisters, European and "Eurasian nurses, were employed on plague from the "J. J. Hospital, 11 were inoculated. None contracted "plague except one European nurse amongst the "inoculated. It was a mild attack and she recovered;" did you see these cases yourself?—They were under my continued observation the whole time.

20,530. Can you tell me how many of the non-inoculated got plague?—Only one; Miss MacDougal. She was infected through the mucous membrane of the eye and died. A pneumonic patient spat in her eye. That is a case of infection through the mucous membrane.

20,531. Then you have some evidence with regard to the Cama Hospital nurses?—Yes. Eight worked for several months on plague duty in the different hospitals. Of these there were four inoculated and four uninoculated. Amongst the inoculated there were no attacks of plague. Amongst the uninoculated there were two plague cases, one of which died and the other recovered.

20,532. (*Prof. Wright.*) You spoke of a series of coryza cases; had any of these patients buboes?—The glands of the neck subsequently enlarged. They had no buboes in the first instance.

20,533. Did any of these patients die?—Yes, several.

20,534. Did you succeed in tracing a connection between those coryza cases and other cases of plague?—No. They came from Thana, an outlying station.

20,535. You said that these cases were the starting point of an epidemic on Mazagaon?—Yes; that information was given to me by Dr. Weir.

20,536. You did not follow these cases up yourself?—No.

20,537. (*The President.*) In reference to the inoculations you performed, have you any facts as to the history of those who were not inoculated? Did they have much plague or no plague after the others had been inoculated?—I cannot tell you that.

20,538. There might have been none?—There might have been none, but I think there was plague among them. Plague was going on very severely all round.

20,539. With regard to the servants who had plague on Malabar Hill, how do you account for their having plague and for the friends living in the same compound, whether Europeans or natives, generally escaping the plague?—By the different conditions of housing.

20,540. Will you describe the difference?—The servants have small rooms, and if they are left to themselves they close the windows at night and shut the doors and live in a close, confined atmosphere.

20,541. You attribute the infection in their cases to the inefficient ventilation and light?—Yes.

20,542. I thought you told us that in the case of your own servants the hygienic conditions were good?—They were very much better than the general conditions of the ordinary natives.

20,543. Better than those you now refer to as the average conditions on Malabar Hill?—No; I think they are about the same all over Malabar Hill.

20,544. I thought you told us that the average conditions were bad. I suppose you admit that they are as bad as you have described them?—Yes.

20,545. But you previously told us that, in reference to your own servants, the conditions were good. How do you reconcile these two statements?—I mean that the conditions were good provided that the people themselves maintained those conditions.

20,546. Is it within your own knowledge that the servants in your compound did maintain good hygienic conditions in their houses in regard to air and light?—Yes, they did.

20,547. And they contrasted favourably with the general standard?—Yes.

(Witness withdrew.)

(Adjourned till to-morrow.)

* Report on the Bubonic Plague in Bombay" by Brigadier-General W. F. Gatacre, D.B., C.S.O., Chairman of the Plague Committee, 1896-7.

At The Secretariat, Bombay.

FIFTY-THIRD DAY.

Wednesday, 22nd February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX, (*Secretary*).

Khan Bahadur N. H. CHOKSY called and examined.

Khan Bahadur N. H. Choksy.

22 Feb. 1899.

20,548. (*The President.*) What are your medical qualifications?—I am a Graduate of Medicine of the Bombay University.

20,549. Are you in the employment of Government?—No, I am in Municipal employment.

20,550. You have been in charge of Arthur Road Hospital ever since the plague began?—Yes.

20,551. (*Dr. Ruffer.*) How many cases of plague, altogether, have you seen?—Altogether nearly 4,000 cases have been under me; most of them have been seen by me personally.

20,552. You are of opinion that there are several types of plague?—Yes.

20,553. *Pestis minor, pestis ambulans, pestis bubonica, pestis septica, pestis pulmonaria* and non-typical forms of plague?—Yes.

20,554. Do you think these types merge into one another, or are they distinct?—I think they are quite distinct except in the case of the septic type where the simple bubonic form merges into the septic.

20,555. Do you think there is a special form of pneumonic plague?—Yes, there is.

20,556. Could you give us the symptoms of *pestis minor*?—The symptoms commence with a little febrile re-action lasting for a day or two accompanied by malaise, pain and tenderness and one gland may be enlarged. After a little rest in bed and ordinary treatment, or practically without any treatment, the patients recover.

20,557. How do you diagnose these cases from other bubonic enlargements?—Because they occurred at the time when the epidemic was amongst us, and they have not been observed in other periods.

20,558. Supposing you had no plague in the town, would you still be able to recognise this form of the disease?—From the experience we have now had, we should certainly look upon these cases with suspicion.

20,559. Suppose there had been no plague in the city of Bombay for two years, would you be able to diagnose a case of *pestis minor* without bacteriological examination?—I am afraid not.

20,560. What is the difference between such cases and *pestis ambulans*?—It is the difference of degree. In *pestis ambulans* you will generally find a patient with one or more enlarged buboes going on for a long time, and the buboes either remain as indolent swellings, or they sometimes suppurate after about two, three, or four weeks after the initial symptoms.

20,561. How do you diagnose a case of *pestis ambulans* from any other form of bubonic enlargement?—We exclude all other chances of error, such as venereal contamination or septic poisoning, or wounds or abrasions, and thus we arrive at the diagnosis by a process of exclusion.

20,562. I will put it to you in this way; there were soldiers, in the Shropshire Regiment for instance, with enlarged glands going on for five, six, or seven weeks, or even longer; how could you diagnose a case of *pestis ambulans* from one of these cases?—We take into consideration whether they have been in localities which have been infected, or whether they have come in contact with plague patients, or whether they have remained in areas which are infected, in which case they will certainly be looked upon as suffering from *pestis ambulans*.

20,563. The history of the case or the bacteriological examination are the only data on which to form a diagnosis?—I am afraid bacteriological examination would not be of very much use in these cases except, perhaps, in early stages—perhaps for the first day.

20,564. Then your means of diagnosis are limited?—We diagnose by the clinical features and the surrounding history of the patient.

20,565. Do cases of *pestis ambulans* have initial fever?—Yes, they have.

20,566. Have you ever made bacteriological examination of such cases?—No.

20,567. How do you know that they are cases of plague?—From the enlargement coming on suddenly with a little feverish reaction during the epidemic of plague, and when there is no other cause to account for it, no local injury or venereal taint.

20,568. What is the end of these cases? Does the bubo suppurate, or does it resolve without suppurating?—Sometimes they suppurate and at other times they remain like indolent swellings for a long period.

20,569. How long?—I should say sometimes for months together.

20,570. Without suppuration?—Yes.

20,571. What do you consider to be the simple bubonic form and the simple septic form of plague?—There is the difference of degree only with regard to the symptoms of the simple bubonic and the septic type. The symptoms which are described in the Report* all through apply generally to the ordinary bubonic plague. The septic form, of course, is more aggravated with extensive infiltrations and is more fatal.

20,572. In the pulmonary form of plague the lung symptoms are predominant?—Yes.

20,573. Then you have non-typical forms of plague in which you have slight fever, diffused swellings with more or less infiltration generally over the parotid and cervical glands, absence of glandular enlargements, and pain, and gradual glandular subsidence from the application of cold and the internal administration of calcium chloride. How would you diagnose such cases as plague?—Just in the same way as the first, *minor* and *ambulans pestis;* they occur during the time of the epidemic or during its wane.

20,574. Could you diagnose them unless there was plague about, or without a bacteriological examination?—The diagnosis, I must say, is inferential only: we have made no actual bacteriological examination of these cases.

20,575. Have you ever seen persons contract plague from such cases?—No.

20,576. How do you know for certain that these cases are plague?—They occur during the epidemic, they have a history of exposure to plague infection, they

* Report on Bubonic Plague, upon Observations of 939 Cases treated at the Arthur Road Hospital, Bombay, from 24th September 1896 to 28th February 1897, by K. B. N. H. Choksy

Khan Bahadur N. H. Choksy.

22 Feb. 1899.

have lived in plague-infected areas or houses and they also have fever.

20,577. Have you seen cases of mixed relapsing fever and plague in the same patient?—Yes.

20,578. Have you found in these cases the micro-organisms of relapsing fever and of plague?—Yes, in the same patient.

20,579. Both in the blood?—Yes.

20,580. Are these cases usually fatal?—No, they seem to run a more or less milder course, and there are more recoveries, when there is a mixture of these two diseases, than otherwise.

20,581. Have you ever seen cases of relapsing fever and diarrhœa?—Yes.

20,582. In your opinion are these the cases which have been described as abdominal plague?—I think so.

20,583. Why?—Because I must say I have not up to now seen a single case which could be called a typical case of abdominal plague, a case in which there are no external buboes, and no other symptoms except purely abdominal symptoms. I have not seen a single case of that typical form up to now.

20,584. Have you ever seen cases of cholera simulating plague?—No.

20,585. Have you ever seen cases of relapsing fever together with diarrhœa which looked like cholera?—Yes, very often relapsing fever patients have been sent to the hospital as cases of cholera, and on examination they have been found to be cases of relapsing fever and not of cholera at all.

20,586. What do you think is the ordinary mode of infection in plague?—The most frequent is infection from the skin

20,587. What evidence have you to show that?—The evidence is, of course, seen in the preponderance of the buboes in the inguinal and femoral regions in those people who generally go about barefooted.

20,588. Have you examined the feet of all the patients who had inguinal buboes?—Yes, I have examined them very frequently with scarcely satisfactory results as regards the local re-action except in a few cases.

20,589. In how many cases do you think you have found local reaction?—Not more than five or seven per cent.

20,590. What do you mean by local re-action?—I mean something to show the point of entrance of the virus into the system—an abrasion or any channels of infection in the skin itself.

20,591. Would you consider an ordinary scratch a local lesion?—In this sense, that there is a channel for absorption from that.

20,592. Do not you find in a great many of these cases scratches round the outer malleolus? Do you not find scratches there from the irritation of mosquito bites and so on?—Yes we do.

20,593. Is it not possible that plague might enter through a scratch and leave no local lesion?—Yes.

20,594. I understand that many patients have cracks and fissures on the soles of their feet and elsewhere?—Yes.

20,595. Do you not think plague might come through them?—Yes, it might.

20,596. Without giving rise to any local inflammation?—Yes.

20,597. In a certain number of cases you have found small pimples on the dorsum of the foot?—Yes.

20,598. What did you find inside these pimples?—Bacteriological examination was made on two or three occasions and almost pure cultures of plague bacilli were taken out from them. We made an experiment in some cases by injecting pure carbolic acid into the pimples; the result was there was a sudden cessation of all inflammatory signs in the bubo; the fever subsided, and the patients seemed to show a rapid rate of recovery.

20,599. When you found a pimple on the dorsum of the foot, was the bubo already formed?—Yes, the bubo was already formed, and the history always was, that the pimple preceded the bubo by two or three days.

20,600. When you treated the pimple the bubo disappeared?—It gradually got smaller and all the symptoms abated.

20,601. Do you think the bubo is the sign that the plague-bacilli have invaded the gland already, or do you think that the bubo is due to the absorption of toxines?—That would be difficult to say, except by actual examination of the bubo itself.

20,602. Does not the fact that the antiseptic treatment of the pimple cuts short the disease, point to the possibility that the bacilli have not yet reached the gland?—I should think so.

20,603. You have no facts bearing upon that?—No.

20,604. Have you ever found blisters or primary sores at the point of inoculation?—Yes.

20,605. What are these blisters like?—They were blisters, either with a spherical cuticle over it, or with distinct umbilication on the top. In those cases the appearance was quite peculiar. It seems just as if a circle of glass had been put over the skin and a membrane tied over it, and the umbilication resembled something like that of magnified smallpox eruption.

20,606. Did you find plague bacilli in them?—Yes, I think they were found; I did not make any investigation personally.

20,607. Did you find pus?—No.

20,608. What was the fluid like?—It was serous fluid, more or less stained with blood.

20,609. How long do you find bacilli in the bubo?—Up to the period of suppuration and a little after.

20,610. I suppose at first there are a great many bacilli?—Yes.

20,611. Are they found not only in the bubo, but round the bubo also?—I have no experience of that.

20,612. You say the bacilli disappear when suppuration sets in?—After a time.

20,613. How long after?—Two or three days after the buboes have been incised we found the bacilli almost disappear.

20,614. How did you ascertain that—by cultivation?—By cultivation.

20,615. Do you find that other micro-organisms take their place?—Certainly. The ordinary microbes of pus must be there.

20,616. I want to know whether you found the pus microbes in the bubo before or only after suppuration?—I have not made any investigation previous to the incision of buboes.

20,617. In your opinion the sputum is infectious in cases of pneumonia?—Yes.

20,618. Is it infectious in any other cases as well?—I have seen a case only lately where there was nothing more than ordinary bronchitis, when the sputum was bronchitic, and still the plague bacilli were found in almost pure cultures.

20,619. Do you find it, in septicæmic cases, as a rule in the sputum?—Yes.

20,620. Do you find it in all cases in which you get secondary affection of the lungs?—If there is any infectious sputum it is found; but I have made no distinct investigation with regard to that.

20,621. Supposing a patient does not spit but has a slight cough, do you find the bacilli in his sputum then?—I have made no investigation with regard to that. I may be allowed to add that most of my practice has been clinical; I have had very little time, and have done very little bacteriological work myself.

20,622. Do you think the disease is contracted by inspiration?—Yes; it must come through inspiration in cases of pulmonary plague.

20,623. Why?—Because the lungs are the primary seat of infection, and we find the absence of plague-bacilli in the blood.

20,624. Supposing you get a cut on the foot and get a bubo in the groin, you find no bacilli between the foot and the groin; supposing on the other hand, instead of having a bubo in the groin, the secondary lesion was in the lungs, *i.e.*, plague-pneumonia, would you find bacilli either in the blood or in any other organ?—I have made many examinations with regard to the blood, and have found that in some of the most typical cases of plague which have proved fatal there was a total absence of plague-bacilli in the blood from cultures.

20,625. How do you think the plague-bacillus is inspired into the lungs? I believe that you agree that it is not to be taken by the digestive canal?—Yes.

20,626. How does the bacillus get from the mouth into the lungs?—It must go with the inspired air. Besides, there is a certain amount of desiccation when the sputum is thrown about and gets dried up.

20,627. You think it is the dry sputum which is inspired with the air?—Yes.

20,628. Have you any evidence to show that the bacilli of plague will resist dryness?—I have no personal knowledge. There is this to be said, that the class of people from which we draw our patients are in the habit of spitting about anywhere and everywhere, in any part of the house. You will find that the sputum must lodge in the different parts of the room, and you will find it in various stages of dryness or moisture; it is quite likely that some of that may be absorbed, and produce the symptoms.

20,629. You have no evidence to show that plague-bacilli resist dryness?—I have made no experiments with regard to that.

20,630. Have you any evidence to show that either the fæces or urine are infectious?—No. Examinations were made, but we did not succeed in getting any plague cultures out of them.

20,631. You do not believe in the possibility of infection through the alimentary canal?—No.

20,632. Why not?—I have seen no evidence to support that view.

20,633. You have seen nothing like an abdominal case of plague?—That is so.

20,634. Have you ever seen primary lesions which you think were primary in the intestines of plague patients?—No.

20,635. Do you think that the vomited matter is infectious?—I do not think so.

20,636. Has not that a bearing upon the possibility of infection by grain?—I think it has indirectly; if the grain were the channel through which the plague germs entered, the primary symptoms would be in the intestinal tract or abdominal cavity.

20,637. Do you think the grain infectious?—No, I do not think it is infectious.

20,638. Some people say it is. For the sake of argument, we will assume the grain is infectious; how can it be infectious?—In the first place, most of the grain which is used is cooked; therefore, seeing that heat is destructive to the plague bacilli, there can be no infection, the bacilli would be destroyed.

20,639. Then the only way in which grain could be infectious is by handling it, the bacilli entering through cuts in the fingers?—In that case there would be no possibility of its entering directly into the alimentary canal.

20,640. Have you any evidence to show that flies, fleas, ants, bugs, and mosquitoes are infectious?—I have no evidence.

20,641. Have you ever noticed that the primary lesion in plague was just in places which would be likely to be bitten by fleas or bugs?—The exposed parts are always likely to be bitten by fleas, bugs, or ants.

20,642. How can the dorsum of the foot get infected from the earth? You say in your précis that, in a great many cases, the primary lesion was on the dorsum of the foot?—It may be through an existing abrasion. There have been cases in which infection has gone into the system through shoe-bites.

20,643. Would it be produced there by scratching, or flea bite or mosquito bite?—It is possible.

20,644. The natives sit a great deal with their hands on the earth?—Very often.

20,645. Do you think that fleas, ants, and bugs, might predispose to plague by producing local lesions which may be scratched?—The poorer classes of people are always full of scratches and lesions, without any bugs or fleas or any other extraneous agents.

20,646. What is the incubation period of plague in your opinion?—I think it varies from about three days to a fortnight.

20,647. Why do you think so?—In cases of mild form, like *pestis ambulans*, we have found from investigation that the period of incubation has been over the normal limit. We have put down ten days; it has gone up to a fortnight.

20,648. Could you give us a typical instance?—I can cite the case of a patient who came from Calcutta on a ship called the *Cleobaria*. The ship left Calcutta, touched at Colombo, and then came to Bombay. Thirteen days after the ship had left Calcutta, the man developed fever and bubo in the groin. He had no venereal taint and nothing to account for it, no injury. He was brought to Bombay and sent to the hospital. We made a close investigation of the case, and we found that the bubo had already softened, and in two days it suppurated. An incision was made, and we found that the contents were the ordinary slough found in cases of plague.

20,649. Did you find plague bacilli?—Unfortunately the investigation for plague bacilli was made too late—about 36 hours after the bubo had been incised and dressed with antiseptics.

20,650. Was there plague in Calcutta at the time?—It was not reported to be existing at Calcutta at the time. There was a great deal of controversy with regard to that particular case.

20,651. Where would he have got plague if there were no plague cases in Calcutta?—I am inclined to believe there were plague cases in Calcutta amongst the poorer classes.

20,652. What was the exact date?—It was the year before last. The patient was admitted into the Arthur Road Hospital on the 6th of October 1897.

20,653. Why do you think that case was plague? Was it simply from the appearance of the bubo?—Yes, and from the history of the case, the man having been in an infected locality in Calcutta.

20,654. But you have no evidence to show that Calcutta was infected?—They had cases of plague in Calcutta at the time. I do not know whether they were officially declared or not.

20,655. Do you think that the power of resistance or the general state of health of the patient may extend the incubation period?—Yes.

20,656. Have you any evidence to show that?—There is no direct evidence bearing upon the point, because it is impossible to fix the day upon which the poison could have been so absorbed.

20,657. It is simply an impression on your part?—Yes.

20,658. Have you any typical cases showing that the incubation period was over three days, or is it simply your impression?—There was a very typical case which I came across four months ago, the case of a Parsee lady. I was called to see her, and I found that she had ascending lymphangitis extending from the inner malleolus right up to the femoral region, with enlargement and pain of the inguinal and femoral glands. It seemed to me there was also an iliac (pelvic) bubo. I examined her very closely and I found nothing. When I came to the heel I found that there was a regular sore. I inquired as to when that sore appeared. She said that ten days before she had been to the Fort and had put on a new pair of shoes; the same day she developed that sore. Ten days after the development of that sore she had the bubonic symptoms. This indicates a period of incubation of ten days, the formation of the sore, and probably the inoculation of the poison, occurring at about the same time. She was living in a non-infected locality.

20,659. Did you find plague bacilli in that case?—It was not bacteriologically examined; it was treated with curative serum.

20,660. Did she recover?—She recovered. She had a bubo on the opposite side as well; she had a left pelvic bubo afterwards which developed in the course of the disease.

20,661. Did the buboes suppurate?—No, they resolved.

20,662. Do you generally find lymphangitis extending from the point of inoculation to the buboes?—Not always.

20,663. Do you find it frequently?—I have seen a great many cases.

20,664. Coming now to the clinical symptoms; can you give us any information as to the attitude of the patient?—I have described the attitude of the patient

Khan Bahaaur N. H. Choksy.

22 Feb. 1899.

in my report*; the attitude is very greatly influenced by the condition of the patient as regards delirium or meningeal symptoms.

20,665. Is not the position of the bubo an important point with regard to the attitude of the patient?—Not particularly.

20,666. Does he not generally draw up his leg on the side of the bubo?—No; the general position is the extension of the legs, one leg crossed over the other; it is almost invariable. In children, drawing up of the leg on the affected side is more often noticed.

20,667. Does he not generally flex his legs—one crossed over the other?—Only when the infiltration is very great; otherwise, if the tension is not so very great, you will find the legs extended; that is what I say in my report,* that the attitude of patients depended upon the stage in which they were admitted. Generally, they were too far advanced to assume any characteristic position; but if recumbent they generally lay flat on the back, with the limbs extended and almost invariably one leg crossed over the other. This was so often observed and so persistent, that every time a thorough examination had to be made, the legs had to be separated apart. Otherwise, the position of the body depended upon the nervous condition of the patient. In the apathetic cases, the patient would generally lie on the one or the other side, with the arms and legs flexed, the former against the chest and the latter against the abdomen, in fact literally doubled up. If the patient could assume a sitting posture, the attitude indicated thorough prostration and helplessness, the head bent upon the chest, the arms and legs hanging listlessly.

20,668. Have you ever noticed anything peculiar about the gait of the patients?—They have a tottering gait.

20,669. Do you attribute that to the weakness of the limbs?—Yes; want of co-ordination.

20,670. But does not that peculiar staggering gait come on long before the patient is weak?—It comes on on the second or third day.

20,671. Does it not come on at once?—No, not at once, I may mention that I have had very few opportunities of seeing fresh cases; most of the hospital cases are in an advanced stage.

20,672. There is something characteristic about the aspect of the patients?—Yes.

20,673. Would you describe that?—The aspect of the patient was almost always characteristic, although it was considerably obscured during the height of delirium. Ordinarily, the plague seemed to be stamped upon the patient's features, giving it a characteristic, and not to be easily forgotten, appearance. The features depicted fear and anxiety, or sadness and resignation, as if from an intuition of the impending fate. In fact, what is called *facies pestica*, so characteristic of the affection, is typified in this mixture of dread anxiety and resignation.

20,674. I suppose the aspect of the patients afterwards varies with the condition of his lungs or his mental condition—whether he is delirous or not; there is nothing peculiar about it afterwards?—That is so.

20,675. Have you ever noticed anything special with regard to the speech of the patient?—The speech is always characteristic. It resembles that of a person under the influence of drink. At first the syllables are all spread out, the voice is thick and husky; sometimes it is very sharp, and the patient replies in a very angry tone.

20,676. Some patients are very irritable?—Yes.

20,677. Most of them are resigned?—Yes; of course then they are in a semi-comatose condition, having huskiness and thickness of speech.

20,678. Have you ever noticed aphasia going on during the course of plague?—Yes; it comes on very suddenly.

20,679. It is complete aphasia?—Yes.

20,680. The patient cannot articulate a single word?—No.

20,681. It is not only aphonia, but complete aphasia?—Yes; absolute aphasia; when the patient recovers he seems to speak like an infant first learning a word; although he is able to articulate, there is a complete loss of memory of words which sometimes lasts for a very long time, sometimes extending over a year or a year and a half before he completely recovers his speech.

20,682. He understands everything that is said to him?—Yes.

20,683. You say in your précis that there is a period of general malaise preceding the appearance of the bubo; is that usually the case?—No, not as a rule; of course it is impossible to get any information from these patients. Some of the more intelligent said that they felt out of sorts for some time.

20,684. Do not the bubo and the rise of temperature come on suddenly and very frequently without any warning?—Yes, rigor and rise of temperature, followed by the appearance of the bubo.

20,685. Have you seen any cases where there was no warning at all where the man has suddenly become very ill?—Yes; while at his work.

20,686. Does the temperature go up very suddenly, or slowly?—There is a difference as regards that in different cases; because we know that in some cases that have virulent infection, the temperature goes to the maximum within the first 24 hours, and rises up to 107 or 108.

20,687. How long does it take as a rule?—It takes three days to attain the maximum.

20,688. Does it go up more quickly in children than in adults?—Yes.

20,689. Do you think the rise in temperature in children is frequently greater than in adults?—Yes, frequently greater.

20,690. Is the temperature a criterion with regard to the gravity of the case?—No, the temperature alone is not a criterion as to the gravity of the case.

20,691. Do you mean to say that you have had very fatal cases with a high temperature?—And also with a low temperature.

20,692. Is the temperature a remittent one?—Yes, it is remittent.

20,693. When do you get remissions?—Practically, the remissions commence on the second or third day.

20,694. It goes down in the morning?—Yes, and rises in the evening. There is a difference of about a degree or a degree and a half between the morning and the evening variations.

20,695. What is the highest temperature you have ever observed?—110°.

20,696. When the patient gets well does the temperature fall down suddenly or gradually?—Generally gradually.

20,697. How long does it take to reach the minimum?—About four or five days.

20,698. And it reaches the normal about the tenth day?—Yes.

20,699. Did you ever get sudden falls of temperature?—Sometimes; they are generally associated with collapse and death.

20,700. Is that sudden fall of temperature sometimes preceded by a rise of temperature?—No, not generally.

20,701. When the bubo begins to suppurate do you get suppuration fever afterwards?—Generally when the temperature goes to about normal on the tenth day we find that the bubo has already suppurated.

20,702. When the bubo is opened do you get further fever?—Further fever goes on only if the slough is underneath the skin or if there is some deep-seated suppuration which we are not able to get at; otherwise the course is only the difference of a degree—between 98 and 99.

20,703. Have you ever taken the temperature after death?—No; but in some cases I have found hyperpyrexia in examining the bodies soon after death; I have examined the patients after death, and sometimes examined them when there was some doubt whether they were dead or not.

20,704. And you have found very high temperature?—Yes.

20,705. But you have never taken the temperature some hours after death?—No.

* Report on Bubonic Plague, by K. B. N. H. Choksy. Bombay, 1897.

20,706. When does the bubo generally appear?—Generally after fever or coincident with it.

20,707. How many hours after the rise of the fever?—Eight or ten hours at the utmost.

20,708. Do you find the appearance of the bubo is delayed sometimes?—Yes; it comes on sometimes as late as six or ten days after the initial fever.

20,709. Do you find that in mild cases or severe cases?—In some severe cases I have seen that—in cases that have terminated fatally.

20,710. Is the pain in the bubo severe?—It is very severe as a rule.

20,711. Is it severe when you leave the patient alone, or only severe when you touch it?—That severity depends upon the tension of the bubo and the infiltration round about it. Sometimes you find a very small bubo extremely tender. In other cases you can move about large masses without pain.

20,712. I am afraid I did not put my question clearly; suppose you leave a patient alone and do not touch the bubo, is there any pain in the bubo?—Yes.

20,713. What sort of pain?—Dull aching pain; of course, the patients are not able to describe it exactly, they say it is an acute pain.

20,714. When you touch it, is it tender?—Yes.

20,715. Do you find that the swelling extends to some distance around the gland?—The gland gradually gets larger and larger until it has attained a certain size; then there is cessation of further swelling.

20,716. Does an axillary bubo spread down the sides of the chest and arms?—Yes, with a few exceptions, and almost always accompanied with extensive infiltration.

20,717. And the buboes in the neck?—Yes, it is the same.

20,718. Does it sometimes extend to the larynx?—Yes, and presses upon the larynx; it presses on the œsophagus and prevents deglutition.

20,719. What is the exudation like, is it serous?—It is either serous or sero-sanguineous.

20,720. And contains a large number of plague bacilli?—Yes.

20,721. Are there hæmorrhagic symptoms?—Yes, especially in the neck.

20,722. What is the swelling like to the touch?—The bubo feels like a dense mass; the infiltration feels more or less doughy, softish; in fact, you might almost call it fluctuating.

20,723. Do you sometimes get erysipelas from the bubo?—Yes, especially in the cervical bubo.

20,724. Have you found the streptococcus of erysipelas in these cases?—I have not made any examination.

20,725. Do you think the rapidity of exudation is a prognostic sign?—Yes, a prognostic sign, and almost always meaning fatal results.

20,726. You mean when it spreads quickly?—Yes.

20,727. Do you think the size of the bubo is any prognostic sign?—None at all, except that in some cases where there are very small buboes, the cases have terminated fatally.

20,728. Will you put in a table giving the total number of femoral and other buboes, brought up to date and work out the percentages?—(Witness subsequently submitted a statement* showing the position of buboes and mortality in 2,723 cases. He explained that, on account of pressure of work, it was not possible to supply the figures for 4,000 cases.)

20,729. Does inflammation of the lymphatics spread from the point of inoculation to the bubo?—Yes.

20,730. Does it spread from the bubo to other buboes?—Yes.

20,731. You have seen that?—Yes.

20,732. I suppose the bubo may slough, may it not?—Yes.

20,733. What is the character of the slough?—The slough is very peculiar; there is generally a mixture of slough and pus; I mean you find the buboes softish, and when you make an incision all you find is that it contains a central cavity with a drop or two of pus; and the whole mass is sloughy; the slough is very hard and sometimes almost cheesy, at other times it looks like a thick tissue, something between cartilage and muscular tissue.

20,734. Does it separate easily?—No, it takes a long time; in only a few cases is it possible to take out the whole gland *en masse*.

20,735. Do granulations form easily, or is the healing slow?—The healing is not very rapid, although granulations seem to form soon.

20,736. I think you said in your report* that it sometimes takes a very long time to heal?—That depends upon the state of the infiltration. In ordinary suppuration with very little or no slough, you find the incision heals very quickly. When the pus and sloughs are extensive or buried between the sheaths of muscles they take a much longer time.

20,737. Do you find the pus has the tendency to extend between the muscles and in the muscular tissue?—Yes; sometimes it forms a regular abscess.

20,738. When the bubo is in the iliac or femoral regions?—Yes.

20,739. When the bubo is in the femoral region, does the pus burrow as far as the popliteal cavity?—Yes.

20,740. Of course, that takes a long time?—Yes; the patient dies from exhaustion by the suppuration.

20,741. Have you seen sloughing of the muscles of the abdominal wall?—Yes, but I think that is generally due to the caustics applied by the patients themselves, except in cases of local necrosis. There is a regular dissection of the abdominal wall.

20,742. Have you ever seen sloughing of the genital organs?—Yes; the whole scrotum sloughs, and the testes have been exposed; in females you will find the labia in an almost gangrenous condition.

20,743. What is the pus like?—Sometimes it looks a thick creamy healthy pus, as we find in ordinary abscesses; at other times it is thin and watery; sometimes it is stained with blood.

20,744. You say in your précis it is an acrid pus?—I mean the irritant pus.

20,745. You mean, it irritates the parts around it?—Yes.

20,746. Do you find that the blood vessels suffer in a bubo?—I think they are easily cut, and their walls become soft.

20,747. Have you ever had secondary hæmorrhages?—Yes, from ulceration.

20,748. How long did the hæmorrhage last?—We stopped it promptly by tampon, and by means of compression we were able to control it altogether.

20,749. Are you sure that it was the femoral vein?—I think so.

20,750. Hæmorrhage from the femoral vein is usually fatal, is it not?—This case did terminate fatally afterwards.

20,751. Not from hæmorrhage?—No; but it took much time to control the hæmorrhage.

20,752. Do you find the sinuses take long to heal?—Yes.

20,753. What is the cicatrix like?—It is generally puckered in cases with extensive infiltration, and it has sometimes a keloidal appearance.

20,754. With regard to the symptoms in the nervous system, what are the reflexes like?—They are dulled.

20,755. Have you tried the patellar reflex?—Yes we generally have the patellar as well as reflex of the ankle-clonus.

20,756. What is the character of the delirium?—It varies; it may be either a muttering delirium or a most violent and maniacal delirium with homicidal tendencies. The patients try to get out of bed, and run out of the hospital. They try to crawl beneath their beds; they go and fall upon a contiguous bed.

20,757. Is the delirium nocturnal or diurnal?—It is more nocturnal.

* *See* App. No. LXI. in this Volume.

* Report on Bubonic Plague, by K. B. N. H. Choksy. Bombay, 1897.

Khan Bahadur N. H. Choksy.

22 Feb. 1899.

20,758. Is it anxious delirium—do not they show any symptoms of fear?—Not when they are in delirium; it is impossible to say what their exact mental state is at the time.

20,759. Is it more marked in young than in old people?—I think in young and old—but, perhaps, more in infants and children.

20,760. How long does it last?—It lasts from about four to six days; of course there are patients that take a longer course.

20,761. Have you found in patients a tendency to get out of their own beds and crawl into somebody else's bed?—Yes, they do that very often, and we have to tie them down.

20,762. Do they try to assume a certain position?—Yes.

20,763. Do they try to escape?—Yes.

20,764. What is the state of the sphincters?—There is almost always retention of the urine; in fact, every other patient used to have a catheter used.

20,765. When does that come on?—Immediately after the second or third day.

20,766. Do you get involuntary evacuation of the urine in some cases?—Occasionally; except it may be, perhaps, in a patient who is in a comatose condition from over-distention of the bladder.

20,767. Have you ever noticed that patients have a tendency to assume a professional attitude, such as praying?—Yes, such as cart-driving and cab-driving; some were in a devout mood, falling on their knees with their hands clasped, as if in prayer.

20,768. Shoemakers will sit down as though they were making shoes?—Yes.

20,769. Some are extremely merry, are they not?—Yes.

20,770. They burst into peals of laughter?—Yes, and that is associated with tetanic symptoms; almost all those cases of loud laughter are cases in which the tetanic symptoms are developing, or are in full strength.

20,771. Do you mean they get tetanus?—Yes.

20,772. You have seen cases of tetanus occur?—Yes, tetanus with marked spasms and opisthotonos and arching of the neck as well as of the back.

20,773. In patients whose buboes are opened?—No, early cases, on the second or third day.

20,774. Are these cases of mixed infection of plague and tetanus?—It is impossible to say.

20,775. You have not made bacteriological examination of that?—No, the cases all proved fatal.

20,776. They were typical symptoms of tetanus?—Yes; in fact, sometimes the spasm was so strong that all the respiratory muscles were fixed like a board; the use of nitrate of amyl or nitro-glycerine averted death in some cases.

20,777. I think you said that they were all fatal?—I mean averted temporarily.

20,778. What is the sensibility—are they hyper-sensitive?—Sometimes they are hyper-sensitive, and wince before the finger touches the bubo.

20,779. They are afraid of being hurt?—Yes.

20,780. Did you find when you actually touched them that they felt the pain more than the ordinary patients?—The state of pain depended upon their delirious condition; sometimes they are roused out of deep coma by pressure.

20,781. Some are talkative, are they not?—Yes.

20,782. They talk the whole time?—Yes.

20,783. Have you seen instances of hallucination?—Yes.

20,784. Have you seen any hallucination of the sense of smell?—No.

20,785. Where the patient thinks he smells all sorts of things?—No, I have not noticed that.

20,786. Have you seen convulsions?—Yes, especially in children; of course there are something like epileptic convulsions, in some cases before death.

20,787. Have you found as an after-effect of plague a sort of apathetic condition lasting for some time?—Yes.

20,788. How long does it last?—I have seen it last three or four months.

20,789. What are its symptoms?—The patient lies in bed, doubled up, generally with his eyes half-closed; he is not cognisant of his surroundings or of his own personal state; he might pass urine and fæces in bed; he lives a sort of mechanical existence, everything which is forced down his throat he takes, and his mind is a perfect blank during the period.

20,790. He gets into a state of imbecility?—Yes.

20,791. Have you seen mania following plague?—Yes, but only in two cases. If the case takes an unfavourable turn, the patient gets feebler and feebler, is bundled up in bed, extremely peevish, whines or cries when disturbed; gradually it becomes extremely difficult to feed him or administer medicines, and he sinks into a marasmatic condition until death supervenes, the patient dying a complete physical and mental wreck. The condition of the patient in this stage is extremely pitiable, he becomes wasted to a mere skeleton and looks more like a corpse than a living being. The extremities are cold, pulse extremely feeble, eyes half or wholly closed, respiration shallow; there are sordes on the gums and teeth, the saliva lodges between the lips, and at each expiratory effort a little trickles down the angles of the mouth, mucus and bronchial secretion are visible at the orifices of the nose, and may be similarly discharged at each expiration. All the normal reflexes being dulled, the patient is speechless, and takes very little nourishment, or has to be supported on nutrient enemas. Even from this condition recovery is occasionally possible, and has occurred in about half-a dozen cases.

20,792. Have you ever seen hydrophobic symptoms in a patient?—No.

20,793. Have you ever seen deafness?—Yes, deafness is complained of.

20,794. Is that deafness due to some local condition of the ear, or is it central?—It is central.

20,795. Have you examined the ears of the patient?—Yes, very often.

20,796. You have not found local lesion?—No.

20,797. Have you ever found any hallucination of taste?—No.

20,798. Have you ever found permanent loss of speech after plague?—No, not permanent.

20,799. They have always recovered?—Yes.

20,800. Have you anything to say with regard to the circulatory system?—In no other acute infectious disease does the pulse—an index of circulation—present so many variations in force, frequency, volume and tone as in bubonic plague, and in no other disease is the disproportion in the normal ratio between the pulse, temperature, and respiration so divergent. The character of the pulse, apart from its frequency, varies with the course of the disease. The full and bounding pulse which is so often associated with high temperatures is conspicuous by its absence, and in the majority of cases the pulse is easily compressible, extremely feeble and very frequent. The feebleness of the circulation is well demonstrated by the feebleness of the pulse, so much so that in some cases with temperatures of 103, 104 or 105 the extremities may be not only cold, but almost icy-cold, and bathed in cold clammy perspiration. This was, indeed, very characteristic and was often noticed. Another index of the weakened heart's action was the pulse itself which could not be felt or counted at the wrist, and heart beats had to be counted instead. As the case advances, the pulse becomes intermittent, regularly or irregularly, more often the latter, and distinctly dicrotic. The dicrotism in some cases is extremely well marked, and in advanced cases may really be considered a reliable diagnostic sign. There is always a change for the better in this stage of circulation if the patient is going to recover, but, if otherwise, the state of the circulation becomes still graver, as shown yet by another variation in the condition of the pulse. It becomes of a beaded character—in fact, a regular water hammer pulse of aortic insufficiency—and it is not difficult to conceive what is thereby indicated. A step further and the inevitable must happen—failure of the heart's action. And this may be gradual or sudden. In a large number of cases the failure is gradual, the beaded pulse becomes quite imperceptible, the body temperature is scarcely

maintained, the circulation getting more and more feeble, and eventually collapse with fall of temperature and death result. In these cases much could be done to support the circulation and stimulate the heart's action, and it may even be possible in a few cases to avert failure and death. But no such hope can be entertained where the failure is so sudden—so surprisingly sudden,—as even to raise a doubt as to whether the patient is actually dead or not. A patient tries to sit up in bed, or gets out of it, or makes some sudden exertion, and falls down either on the bed or on the floor, and is found beyond all hope. Very often the heart fails suddenly without any exertion on the part of the patient. He may be sleeping quietly and dies suddenly. In sudden heart failure very often there are no indications of cardiac failure, the pulse may be of good volume, and tension, frequently easily compressible, but yet indicating no immediate danger.

20,801. Have you ever found murmurs in cases of plague?—Not distinct.

20,802. Have you ever found leucocytosis in the blood?—Yes.

20,803. What is your experience with regard to that?—In a number of cases examined by myself and Dr. Pöch, of the Austrian Mission, we found the number of leucocytes varying from 12,000 to 28,000. This was the largest number found in any case.

20,804. In fatal cases?—I cannot say that exactly.

20,805. You consider that the presence of bacilli in the blood is a grave prognostic sign?—Yes.

20,806. In how many cases have you found bacilli in the blood?—Generally, I found bacilli in cases which were very near death, or which had assumed a grave complexion.

20,807. Have you found bacilli disappear from the blood, and the patients recover?—Yes; but in a very few cases indeed.

20,808. In how many cases, do you think?—We had examined about 240 cases all told; but I do not think that in more than four or five cases was the thing observed.

20,809. Have you ever noticed epistaxis?—That is one complication; but it is not common unless the case is mixed with relapsing fever.

20,810. Have you ever seen cases in which the larynx is affected in plague?—Yes; the tonsils are affected first, and the larynx secondly.

20,811. Have you ever seen it secondly affected from the cervical glands?—Yes; and I think primary also, affecting the cervical gland, the poison passing from the tonsils and affecting the neck buboes.

20,812. We have been told that there was a form of primary laryngeal plague; have you noticed that?—I think the laryngeal plague is more a case of cervical buboes, with pressure upon the larynx from a mechanical cause.

20,813. Have you ever seen a pseudo-diphtheritic membrane on the tonsil?—Yes.

20,814. In cases where the bubo was in the neck?—Generally.

20,815. Do you, then, consider the tonsils are the point of entrance?—I believe so.

20,816. But it may be, possibly, brought in by food?—It may be from ordinary inspiration.

20,817. Or by food?—If the food is the channel, you ought to see some abdominal symptoms as well as infection of the tonsils.

20,818. Supposing the virus has been stopped at the tonsils?—That would show a selective action on the part of the tonsils to take up the whole virus, and not allow any to go into the stomach.

20,819. Supposing it went into the stomach, would it not be killed by the gastric juice?—You mean to say the secretion of the mouth would not interfere with it also?

20,820. You have no facts with regard to that?—No.

20,821. Is the hypostatic congestion of the lungs common?—Yes.

20,822. Did you find plague bacillus in the sputum in cases of hypostatic congestion of the lungs?—There is hardly any sputum in some of these cases.

20,823. Is the œdema of the lungs a common symptom?—Yes.

20,824. When does that supervene?—Generally, on the third day.

20,825. Do you think the œdema of the lungs is generally due to recumbent position, or to something more?—I think it is due to the recumbent position and flagging circulation.

20,826. You have already told us about primary pneumonia; did you get secondary pneumonia in plague?—Yes.

20,827. What organisms did you find then? Did you find the pneumo-coccus or bacillus of plague?—Both have been found in the same patient.

20,828. Is it lobular pneumonia?—Yes, in small isolated patches.

20,829. We have been told, in certain cases, that you get the whole of the lung, or a large part of it, involved; have you seen any such cases?—No; we have made several *post-mortems*.

20,830. It has always been lobular?—Yes.

20,831. What are the characteristics of the tongue?—The tongue is dry, and covered with a thick white fur in the centre; it is red at the tip and edges. The character of the tongue varies with the disease. In advanced, and neglected, cases it is of a brownish colour, and of regular rusty appearance; the lining chips off in flakes, leaving ulcers.

20,832. Have you ever seen a tongue of which the centre is perfectly clean and the two sides are furred?—I do not recollect such an instance. (Note by witness on correcting proof of his evidence—I have seen one case since the above evidence was recorded.)

20,833. You do not think it is a characteristic of plague?—No, it would not be common.

20,834. Have you ever seen acute glossitis in plague?—Yes.

20,835. What are the characteristics of that?—It is generally associated with cervical buboes and infiltration; the tongue is almost round over one-half and the other half is enormously swollen: the patient is unable to open his mouth, and has difficulty of respiration and deglutition.

20,836. Have you seen it in septicæmic plague?—I cannot say whether these cases are septicæmic.

20,837. Have you seen hæmorrhages from the tongue?—No primary or direct hæmorrhage except through ulceration.

20,838. Have you ever seen fissured tongues which bled?—Yes.

20,839. In septicæmic cases?—Yes, I think so.

20,840. What is the appetite like?—The appetite is almost nil in some cases; occasionally, in the acute stage, the patient asks for food or says he is hungry.

20,841. We have been told that the appetite is preserved in a good many cases; that is not your experience?—I do not think so, the patients take whatever is given to them by the nurses, and they have very little choice in the matter, they might like it or they might not like it, but they usually do not ask for food or say that they feel hungry.

20,842. Is thirst very great?—Yes.

20,843. Is it a marked symptom?—Yes, they always call for ice water.

20,844. Is the vomiting bilious?—Yes, generally; I think it is due partly to the calomel and soda which they get as treatment when they are admitted; but, apart from that, vomiting is at times very persistent and troublesome.

20,845. Lasting several days?—Yes.

20,846. Have you noticed any blood in the vomiting?—Occasionally.

20,847. Have you noticed hiccough?—Yes, it is very persistent either in acute or convalescent cases.

20,848. How long does it last?—It may last for a fortnight, practically defying all treatment.

20,849. Have you found that in septicæmic cases and bubonic cases only?—Yes.

20,850. What is the state of the bowels?—Generally costive; diarrhœa comes on just before the critical period, just before death, in some cases.

20,851. There is nothing special about the motions?—No, except a peculiar smell, which I found very characteristic and very offensive.

Khan Bahadur N. H. Choksy.

22 Feb. 1899.

20,852. Have you found that melæna is a common symptom?—It is observed in a certain number of cases.

20,853. Is that observed just before death?—No, as an ordinary complication.

20,854. Do you think a patient has frequent hæmorrhages in the bowels?—Yes, and in the stomach also in some cases. There is coffee-ground vomit, partly-digested blood, and sometimes almost pure blood, is brought up.

20,855. What are the characteristics of the urine?—It is always highly-coloured and albumen is present, the chlorides are diminished, and there are always hyaline casts.

20,856. Have you ever seen uræmic symptoms?—No.

20,857. Have you ever found bile pigment in the urine?—Yes.

20,858. Frequently?—Yes.

20,859. How do you test for it?—By nitric acid and sugar, I think.

20,860. In another report, I find that the free excretion of urea and uric acid and absence of albumen blood and renal casts in the urine are favourable signs, and the return to the normal quantity secreted and the presence of chlorides one of the first signs of amendment; is that your experience?—Yes, the chlorides do gradually commence to increase as the condition of the patient ameliorates.

20,861. Do you think that the catamenial discharge has any influence on plague in women?—It is brought on prematurely by plague.

20,862. Do you find it has a bad influence on the course of the disease?—It might have, indirectly, by causing too profuse hæmorrhage, and thereby further weakening the patient.

20,863. Is it your experience that it is so?—I think so.

20,864. I believe pregnant women usually abort and die?—Yes, recoveries are very rare.

20,865. There is an idea among people that syphilis protects against plague; have you ever seen a syphilitic patient with plague?—I have seen patients with fresh venereal infection and having all the symptoms of plague in them. I do not know about constitutional syphilis of long standing—I have had no experience of that.

20,866. But you have seen primary syphilis and plague in the same patient?—Yes.

20,867. Do you ever see plague in the fœtus?—No, I have not made any investigations with regard to that.

20,868. What have you to say with regard to cutaneous and cellulo-cutaneous symptoms?—The cutaneous manifestations of plague are many and various, and may be noted as:—(*a.*) Ordinary blebs or blisters. (*b.*) Blebs or blisters with hæmorrhage or acrid serous pus. (*c.*) Dark depressed blisters, ordinarily called black boils. (*d.*) Localised cutaneo-cellular necrosis. (*e.*) Gangrene. (*f.*) Abscesses.

(*a.*) Ordinary blebs or blisters.—These with serous contents were observed in a few cases at an early stage. The blister comes on generally without any appreciable cause or after, perhaps, slight friction, the limbs becoming somewhat hot. If punctured, the contents are perfectly serous like those of any ordinary blister, but the cuticle appears of a dark brownish colour. The surrounding skin may have a threatening darkish look and if not properly attended to, the limb may become gangrenous.

20,869. Are these primary lesions you speak of on the dorsum of the foot, for instance?—Not necessarily.

20,870. You say that the limbs become gangrenous; how far does the gangrene extend?—I have seen it extend almost to the half of the lower extremity.

20,871. Does the patient lose the limb?—Generally, a line of demarcation forms; I have not waited for that, I generally injected the sublimate at the periphery just where it was spreading; that has checked further spread of the gangrene.

20,872. Did you ever have to amputate?—No.

20,873. Will you proceed, please?—(*b.*) Blisters with hæmorrhagic acrid serous pus.—These were observed in some advanced cases, the blisters covering almost the whole body, but more especially the limbs, and running together into large shapeless bags. The contents were generally made up of unhealthy pus or a mixture of it with blood.

(*c.*) Dark depressed blisters.—The so-called "black boils" were observed in a large number of cases, and they seem to bear a distinct causative relation to the buboes in their neighbourhood. They differed from ordinary boils in that no inflammatory aureola surrounded them. They consisted essentially of a blister, in which the cuticle had become raised sharply and evenly from the skin, without any redness or signs of inflammation. In fact, it appeared as if a glass circle had been fixed over the skin and its top tied with transparent tissue paper. The top was centrally depressed or umbilicated, and from this there descended to the bottom a central slough, reaching down to the skin. The space around the slough was filled with pus or sero-sanguineous fluid. When the cuticle was removed and the central core or slough separated from the base, there remained a punched-out unhealthy looking ulcer which was difficult to heal, and took a long time to granulate. If seen early, the cuticle of these blebs used to appear normal.

20,874. Did you ever see localised cellulo-cutaneous necrosis?—Frequently.

20,875. What does it look like?—In the advanced stage you will find a large dark greenish looking surface, surrounded by inflammatory aureola, which is depressed in the centre, with a line of demarcation all round.

20,876. It looks like wash-leather?—Yes.

20,877. Can you check that in any way?—I have succeeded in checking it by injecting sublimate at the circumference.

20,878. Have you ever seen desquamation after plague?—No.

20,879. Have you seen any eruption of the skin?—Yes; like herpes and sometimes like eczema.

20,880. Where were the eruptions?—They were generally spread over a part of the body; and the herpes were generally confined to the face.

20,881. What part of the face?—Generally along the lips.

20,882. The same as you get in pneumonia?—Yes.

20,883. Is there such a thing as plague-rash?—I have seen in some cases, just before death, small petechiæ spread over the body, or sometimes in contiguity with exudation, but none can be said to be a characteristic sign of plague.

20,884. Have you ever seen gangrene of the limb after plague?—Yes.

20,885. How far did the gangrene extend?—In one case right up to the forearm.

20,886. From where?—I think from the thumb.

20,887. Did the man get a local lesion of the thumb?—I think there was a local lesion.

20,888. Did you have to amputate?—No, the gangrene was also stopped by sublimate. In both the cases in which it was very well marked the sublimate stopped it.

20,889. You had only seen two or three cases of that?—Yes.

20,890. Have you ever seen abscesses?—Yes; they form in all parts of the body.

20,891. Have you seen petechiæ form?—Yes, before death.

20,892. It is said that there is a peculiar smell in plague; have you noticed that?—Yes, I have noticed it very often; very marked, especially when the plague epidemic is at its height.

20,893. Do you think it is more the smell of the dirt of the patient?—No.

20,894. Do you think it is peculiar to the plague?—It is peculiar to the plague; I have often been attracted by the smell, and have asked the nurses to examine the bodies, which they have found to be thoroughly cleaned and disinfected. The smell sticks to the patient even after disinfection.

20,895. Captain Thompson describes it as an earthy, cellar-like smell?—I do not think I can describe it in any particular way.

20,896. Have you ever seen complications of the eyes?—Yes.

20,897. Can you tell us about them?—There is generally ulceration either of the cornea leading to

erforation or hypopyon, or a general destruction of ıe eyesight in a short time.

20,898. What is the cause of that? Is it due to in-ɔction of the eye from the bubo?—No; I do not think ıere can be any direct infection of that kind. There hardly any time for it; it comes on in the acute ;age.

20,899. Do you get conjunctivitis?—Yes.

20,900. Do you think it is due to inability to close the yelids?—There is such an amount of injection at first ·hen the patient gets plague that there is very little ifference between it and acute inflammation; and in-ammation comes on long before there can be any ·ritation from inability to close the eyelids.

20,901. Have you seen any photo-phobia?—Yes. In ome cases there is lachrymation also.

20,902. Do you sometimes get arthritis coming on in lague?—Yes.

20,903. Is that in cases treated with serum?—Yes; nd often in cases not treated with serum.

20,904. How long does the arthritis last?—It may last hree or four weeks. There is no actual arthritis lways; sometimes you will find arthritic pain without rthritis; the patient complains of pain.

20,905. Do you get effusion into the joints?—Yes, and welling.

20,906. Do you ever get pus in the joints?—No.

20,907. In how many cases does it occur?—In about or 5 per cent. of cases.

20,908. Can you tell what are the factors which would ffect the prognosis?—There are very many different auses which lead to it.

20,909. Do you find that stout people suffer more than hin people, and so on?—Stout people die much sooner han thin people.

20,910. You think obesity has a distinct influence?—Yes, I have found some of the Bombay workmen—abourers in the docks—who have got very good hysique—succumb to the infection in a short time, nd die within 24 or 36 hours after infection.

20,911. Can you put in a table of mortality up to the resent time, including all your experience, and giving articulars of race, sex, age, and occupation?—I have ot two tables* here—one, beginning in September 1896, nd ending in February 1899, showing the number of ases treated, and deaths within 24 hours, and deaths ithin 48 hours, the total mortality, the recoveries, nd the percentage of mortality. The other tables equired I will prepare and submit later.

20,912. Do you find that children die more easily from lague than adults?—During the first epidemic, I found hat the incidence of mortality was very great among hildren; but, subsequently, they seemed to make more ecoveries in proportion to the adults. They had con-ulsions and other intercurrent diseases, which also arried them off in large numbers.

20,913. Do you find that many or few children come nto the hospital?—I think a good proportion are hildren.

20,914. Do you find a good proportion of children nder five or six years old coming into the hospital?—Yes.

20,915. What does a patient usually die of?—I think ailure of the heart's action is the primary cause.

20,916. Do you find œdema of the glottis?—In some ases.

20,917. Hæmorrhage also?—Yes.

20,918. Have you ever found nervous sequelæ in plague asting for a long time?—Yes, such as paraplegia, eripheral neuritis, paralysis of the extensor muscles, nd wrist-drop as in lead palsy.

20,919. Have you seen them in the feet, or chiefly in he hands?—Chiefly in the hands.

20,920. Have you ever seen spastic-paraplegia?—No.

20,921. Mental depression?—Yes.

20,922. Have you ever seen dysentery following lague?—It might be there, but nothing marked.

20,923. Have you ever seen relapses in plague?—Yes, have seen they are very frequent, in fact, nearly 0 per cent. or 60 per cent. develop an iliac or pelvic ubo.

20,924. What becomes of the bubo?—It resolves generally, and if it suppurates it means long illness and probably death.

20,925. (*Prof. Wright.*) Do you get another rise in temperature?—Yes, and in fact the patient gets through a regular secondary, but milder, attack of plague.

20,926. (*Dr. Ruffer.*) Have you ever seen a man who had plague twice?—No.

20,927. Do you think that plague brings out certain latent diseases?—Yes, especially malaria and phthisis.

20,928. Do you think it has a good effect on certain infectious diseases?—It might modify them in this way; as relapsing fever and plague modify each other, it is possible that other diseases might be favourably or unfavourably modified. I have seen small-pox and plague together in the same patient.

20,929. How long do you think a patient remains infectious after plague?—After the buboes have suppurated, I suppose all the infection disappears in about three or four days after the opening of the buboes.

20,930. Suppose the patient has lung symptoms as well?—Then it depends upon the duration of the lung symptoms.

20,931. Have you any experiments to show that the plague bacillus remains in the lungs of a plague patient for some length of time?—No.

20,932. The late Doctor Davda, who got plague in the hospital, had 10 c.c. of Doctor Yersin's serum injected as a preventitive about three weeks previous to his illness?—That is so.

20,933. And he had plague and died?—Yes.

20,934. Can you tell me anything about Dr. Galeotti's serum?—The first time that that serum was used in Bombay was in June 1897. We had only six cases in Bombay, and they gave very satisfactory results. That was the first experience, just when the first epidemic was declining.

20,935. How did you choose those six cases?—They were not selected; they were injected as they came in. At that time the admissions were few, and there was not much chance of making any selection.

20,936. Have you the details of these cases?—Yes.

20,937. Have you notes?—Yes.

20,938. Can you put them in, with the temperature curves?—Yes. (Witness subsequently stated that no detailed clinical notes of the cases treated were kept on account of pressure of work and want of proper assistance. The charts of all the patients were, however, available, with such remarks as were made on the same at the time of treatment and after death. These he forwarded together with a report on all cases treated with serum in the hospital.†)

20,939. Do you find that the injection of Dr. Galeotti's serum produces any marked effect on the temperature?—Yes, it does, if one or two injections have been made.

20,940. What happens?—The temperature falls by about three or four degrees, and there is a general improvement in the condition of the patient.

20,941. Improvement shown in what way?—As regards his mental condition and circulation and buboes.

20,942. Anything else?—The buboes cease enlarging, and some altogether disappear. Of course, we go on injecting the serum by greatly diminishing doses until the temperature comes to the normal and stops there.

20,943. Have you had any experience of it since those first six cases?—We had 257 cases done last year, which gave us 145 deaths and 112 recoveries, a percentage of about 56 mortality.

20,944. What is the normal mortality in your hospital?—The normal mortality is 71 per cent.

20,945. How did you choose these cases?—At first we took all cases. We found that there were about 30 moribund in the list of 257 treated; we found that the serum was simply wasted upon them, and, subsequently, we eliminated all the moribund and all the convalescents and semi-convalescents.

20,946. When do you begin to do that?—In April.

* *See* App. No. LXI. in this Volume.

† *See* Report by K. B. H. N. Choksy on cases in the Arthur Road Hospital, Bombay, treated with serum, with six charts of cases treated in June and July 1897, and 47 charts of cases treated in March 1899, printed in this Volume as Appendices Nos. LXII. and LXIII. In App. No. LXII. is also included a report on Lustig's serum by Captain L. F. Childe, I.M.S.

Khan Bahadur N. H. Choksy.

22 Feb. 1899.

20,947. After doing how many cases?—About 50 or 60 cases in the early days.

20,948. Then you eliminated all the moribund and convalescents and semi-convalescents?—Yes.

20,949. In spite of that, your mortality remains 56 per cent.?—Yes, the mortality of the moribund is included in the 56 per cent. Thirty cases are included; if they are eliminated, the percentage is about 49 or 50.

20,950. Did you eliminate all the cases that had been ill for some time, or did you choose your cases in any way?—We did not select them; we took them as they came in.

20,951. Did you inoculate every case that came in, or every other that came in; did you get controls?—With regard to controls, there is a great deal of difficulty. There is great difficulty in getting proper controls.

20,952. Will you continue your explanation with regard to controls?—I find there is a great deal of difference with regard to the races from which the patients are selected, one race having a higher mortality than another; then, again, the position of the buboes has a great deal of influence with regard to the mortality, axillary buboes, for instance, giving a mortality of 82 per cent., whilst the inguinal buboes have a mortality of only 66 per cent. Controls, in order that they may be proper for comparison, must be more or less similar as regards age, sex, race, duration of disease, position of buboes, general condition, and the state of the circulation. If they do not answer to these requirements, any conclusions arrived at must be fallacious. And it is not always possible to get such controls. The following tables bring together the statistics I have compiled of cases in 1898 treated with the serum and those not so treated:—

TABLE showing the NUMBER of CASES treated with Prof. LUSTIG'S SERUM during 1898, and comparing the MORTALITY between SERUM and NON-SERUM CASES.

1898. Months.	No. of Cases treated with Serum.	Died.	Recovered.	Percentage of Mortality.	Percentage of Mortality in Non-serum Cases.
March - -	35	23	12	65·71	75·89
April - -	95	59	36	62·11	69·37
May - -	43	20	23	46·51	73·68
June - -	—	—	—	—	57·14
July - -	9	3	6	33·33	90·90
August -	13	6	7	46·15	83·33
September -	38	20	18	52·63	96·72
October - -	24	14	10	58·33	95·12
Total -	257	145	112	56·42	79·12

	No.	Died.	Recovered.	Percentage of Mortality.
Non-serum cases during the same period.	752	595	157	79·12

The above 257 cases include over 30 moribund cases. Subsequently all moribund cases were excluded, and so also all semi-convalescent and convalescent cases. The cases thus treated represented the average type of ordinary acute cases. In the deaths from serum-treated cases have been included several cases that had died during convalescence, at periods varying from four to ten weeks after the injection of the serum. In fact, they had died from intercurrent diseases, and not strictly from plague.

20,953. Have you excluded from these tables all the pneumonic cases?—We had no primary pneumonic cases.

20,954. What are the other good effects you noticed from Dr. Galeotti's serum?—The convalescence was rapid and there was less suppuration of the buboes.

20,955. Had it any influence on the cough of the patient?—Not that I noticed particularly.

20,956. Did you make any observations of micro-organisms in the blood?—They were made in my presence by Dr. Galeotti in two or three cases only; and it was found that the micro-organisms disappeared after the injection of the serum. Cultivations were made.

20,957. Did you notice anything else?—No.

20,958. I believe you had some experience with regard to Prof. Haffkine's serum?—Yes.

20,959. How many cases?—That was in December 1896 and January 1897. There was a mortality of 40 per cent.; 14 of those were acute cases, of whom six died and eight recovered, giving a mortality rate of 42·85 per cent. The number, however, was very limited. Then we had another trial with Prof. Haffkine's serum, side by side with Prof. Lustig's serum. There was no difference in the mortality between the serum cases and the non-serum cases.

20,960. Was there any difference in the mortality between Prof. Haffkine's series and Prof. Lustig's series?—Yes, in favour of Prof. Lustig's series.

20,961. You say that Prof. Haffkine's inoculation gave a percentage of mortality of 42·85, whereas Prof. Lustig's gave 56 per cent.?—49 per cent., excluding the moribund.

20,962. How long did you try Prof. Galeotti's serum?—It was tried from March to October.

20,963. What was the mortality in the preceding year from March to October?—Our epidemic of 1897–98 became practically over in June 1898. Then we had a rather severe recrudescence in July, August, September, and October.

20,964. Can you give us the mortality in the same months in the preceding year when no serum was tried?—The mortality during the epidemic:—

In March	1897	was	67	per cent.
In ,,	1898	,,	75	,,
In April	1897	,,	56	,,
In ,,	1898	,,	58	,,
In May	1897	,,	40	,,
In ,,	1898	,,	54	,,
In June	1897	,,	22	,,
In ,,	1898	,,	57	,,
In July	1897	,,	53	,,
In ,,	1898	,,	78	,,
In August	1897	,,	63	,,
In ,,	1898	,,	76	,,
In Sept.	1897	,,	66	,,
In ,,	1898	,,	82	,,
In October	1897	,,	51	,,
In ,,	1898	,,	84	,,

20,965. It was in 1898 that the serum was tried, was it not?—Yes.

20,966. In 1897 the average mortality was lower than 56 per cent., when there was no serum tried?—In 1897 we had no recrudescence during these months.

20,967. In 1897 the mortality was 67, 56, 40, 22, 53, 63, 66, 51 per cent., and in 1898 it was 75, 58, 54, 57, 78, 76, 82, 84 per cent.?—That is so.

20,968. Therefore the percentage was considerably higher when the serum was used than when it was not used?—The percentage was higher, not because serum was used, but because of the fact that from June to October 1897 there was no epidemic of plague; there were sporadic cases only: whereas in 1898 we had another severe epidemic during those months.

20,969. But, comparing the two, the proportion is not in favour of the serum?—The comparison would be fallacious, as the conditions were not identical. If we compare the mortality of serum cases and non-serum cases, there is a difference of nearly 23 per cent. in the same period. From March to October 1898 we treated 257 cases with serum, and 752 without serum. The mortality in the serum cases was 56 per cent., and amongst the non-serum cases 79 per cent.

20,970. Do you exclude moribund cases among the uninoculated people?—If we exclude the moribund among the uninoculated the percentage would stand at about 69. It has to be remembered that, among the uninoculated are included convalescent and semi-convalescent cases, otherwise the mortality rate in them would be higher.

20,971. That is only a difference of 9 or 10 per cent.?—Nearly 13 to 14 per cent.

20,972. What have you to say with regard to the *post mortem* appearances? — If it were possible to convey in one word the principal *post-mortem* signs of the changes that are found in the system, that would be hæmorrhage. Hæmorrhages in every conceivable and inconceivable part of the body, hæmorrhages in the dura-mater, in the larynx, in the mediastina, in the epi- and peri-pleura, in the epi- peri- and endocardium, and in the myo-cardium, in the lungs, in the stomach, in the intestines, kidneys, liver and spleen, in the bladder, in the intima of the vena cava and jugular veins, hæmorrhages in and around the buboes and in the subcutaneous cellular tissue of the neck, chest, arm, forearm, thigh, and legs, and even in the retro-peritoneal connective tissue. These hæmorrhages in one form or another were observed in all the 54 autopsies that were made, varying in extent in the organs affected, according to the nature of the case. It may be as well, however, to give a brief summary of the *post-mortem* appearances observed in the various parts of the body.

Brain and Membranes.—The meninges were injected, but hardly any traces of acute inflammation were found, except in one case. Hæmatoma of dura-mater was once observed; excess of fluid in the arachnoid cavity was well marked in a few cases, the ventricles being full, and the choroid plexuses œdematous and swollen. The brain substance showed the gross lesions, but it appeared softer than usual, the convolutions being swollen and œdematous. In fact, stasis had produced changes in the brain similar to those in the lungs, namely, œdema, but in a less degree on account of its peculiar circulation. No hæmorrhage was found in the brain substance.

Spinal Cord.—The spinal cord with its coverings was examined in a few cases, but beyond congestion nothing else was noticable.

Pharynx.—The pharynx was generally found congested, especially so in several cases with infiltrations. A pseudo-diphtheritic membrane of a dirty greyish brown colour was seen in a few cases covering it, as well as the tonsils, and extending towards the larynx. The tonsils showed occasionally abscesses within their substance, with acute inflammation and some hæmorrhage.

Larynx.—The larynx was injected and inflamed, and in some cases hæmorrhage was noticed beneath its lining membrane. The structures surrounding it, as well as the soft parts that line it, were œdematous, and the aryteno-epiglottidean fold was often found to be greatly swollen and œdematous, blocking the entrance and exit of air. The pseudo-diphtheritic membrane, above referred to, was noticed in two or three cases to extend to the larynx with deep cervical buboes and infiltration. The laryngeal symptoms were, as a rule, well marked. The thyroid was generally found to be normal. The trachea showed nothing beyond injection.

Lungs and Pleura.—The lungs were practically "blood-full" and in most cases, when there was not much extensive pneumonia, greatly œdematous. On section, a large amount of sero-sanguineous fluid flowed out of them, in fact they seemed to be thoroughly soaked in it like a sponge. The mucus in the bronchioles was frothy and blood-tinged. If pneumonia existed, it was of the characteristic lobular type, in isolated patches, having a mottled grey appearance, generally well raised above the surrounding lung surface, and surrounded by a ring of conjested lung, gradually merging into healthy lung tissue. Hæmorrhagic infarcts, abscesses, and occasionally a stray tubercle was noticed in some cases. Pleurisy was sometimes met with, and was of a fibrinous character. Hæmorrhages more or less extensive were noticed on the parietal, visceral, and diaphragmatic pleura, the latter being the less frequent, and of the two former, parietal pleura being the most often noticed with large hæmorrhagic patches. Hæmorrhages were also observed in the connective tissue of the anterior and posterior mediastina. The bronchial glands were observed in a few cases to show the characteristic tumefaction and swelling of plague.

Heart.—Pericardial fluid was found in some cases to be larger in quantity than normal. Hæmorrhages were found on the pericardium, epicardium, and also endocardium. They were also met with in the substance of myocardium, which was generally soft and in a state of acute degeneration, occasionally fatty. In some cases it was so soft that it could be rendered pulpy between the finger and thumb. The cavities were generally dilated, the aorta normal, and occasionally fresh vegetations and hæmorrhages were observed on the valves.

Œsophagus.—It was generally normal but in such cases as had extensive hæmorrhage in the gastro-intestinal mucous membrane, it also shared in the same, and showed occasional hæmorrhages.

Stomach.—The stomach was hardly ever found to be in a normal state, its mucous membrane was generally bile-stained and showed hæmorrhages which were extremely characteristic, inasmuch as they were always punctate, the same character being also noticeable throughout the intestinal tract. In the absence of hæmorrhages there was occasionally intense injection and fresh erosion of the mucous membrane.

Liver.—The liver appeared generally slightly swollen "blood-full," and in a state of acute infective degeneration, occasionally fatty. Its substance was soft and friable, and the capsule at times adherent. In one case only emboli of plague bacilli were noticed. The gall bladder was almost always full, containing thick, viscid, dark-greenish bile.

Spleen.—The spleen showed an acute tumor or enlargement, but not large enough to become prominent. It was generally in a state of acute degeneration, the capsule was adherent, and its substance soft, pulpy, and, in some cases almost diffluent, the spleen appearing like a bag containing a homogeneous jelly. Hæmorrhagic infarcts were noticeable on its surface beneath the capsule, and occasionally small abscesses and cysts were present. On section, the colour was of a deep chocolate brown, sometimes almost hæmorrhagic, the Malpighian bodies were swollen, and could, occasionally be distinctly seen, and so also the trabeculæ and the fibrous structure. In cases that had suffered from malaria, the peculiar dark pigmentation due to it was also noticed.

Kidneys.—The kidneys were in a state of acute parenchymatous degeneration, the capsule adherent, and stellate, and other hæmorrhages and hæmorrhagic infarcts were noticed in its substance. The cortex was thin, and the pyramids swollen, and so also were the Malpighian capsules which were at times traceable; small cysts and abscesses were also noticed in its substance. The suprarenal capsule appeared to be normal.

Mesentery. — The mesentery also showed hæmorrhages, and they were, besides, noticed in the retro-peritoneal connective tissue and in the loose connective tissue in the abdomen, surrounding the various organs. In some cases hæmorrhages were noticed on the inner aspect of the abdominal wall and also between the recti muscles. The mesenteric glands were not often seen to be much enlarged or infected. Whenever there was plague infection, they showed slight tumefaction and swelling, and could be at once made out from their dark purplish colour and from the hæmorrhages surrounding them. Hæmorrhages were also noticed in the ovaries as well as around the iliac glands Whenever the glands along the course of the vena cava showed infection, hæmorrhages were noticed in the connective tissue and around them as well as in the intima of the vein extending several inches both ways. The same was also noticeable in the case of jugular and femoral veins.

Intestines.—The intestines, small and large, showed punctate hæmorrhages, and in one case these hæmorrhages extended from the œsophagus to the rectum. The mucous membrane was generally found slightly inflamed, and sometimes slight ulceration was noticed.

Buboes.—The appearance presented by the buboes was quite characteristic, and their section, whenever infected, always showed characteristic appearances such as are not met with in any other affection. They were swollen, enlarged and surrounded by sero-sanguineous or hæmorrhagic exudation. On section, they appeared of a dark-purplish colour and "blood-full," and the appearance, as stated above, was always characteristic. The exudations around the glands have been already described, and so also the cutaneous manifestations found during life. Whenever the parotid was enlarged it appeared like a large lobulated mass, varying in size from four to six inches, and on section all the small component lobuli stood out distinct.

Bones and joints.—The marrow of long bones like the femur was often noticed in a state of acute red degeneration, as in other infective diseases, and the synovial fringes in the knee-joint distinctly infected.

Khan Bahadur N. H. Choksy.

22 Feb. 1899.

The *post mortem* appearances above described are from 54 autopsies that were made in my hospital, 47 by the members of the Austrian Plague Commission, and the rest by the hospital staff. The thoroughness, the extreme care and the intelligence which characterised these *post mortems*, each of them being a complete demonstration, reflect great credit on Dr. Heinrich Albrecht, the head of the Commission, and his assistant, Dr. A. Ghon, who conducted them, and I must own my deep sense of obligation to them for the way in which they utilized the material I had provided, and which forms the basis of these notes, and whatever credit attaches to them belongs to Dr. H. Albrecht.

20,973. How many of the attendants suffered from plague?—Very few; altogether, I think, there were only six of them; all those who contracted the disease were living outside in infected houses and not on the premises, and it is impossible to say whether they had infection from the hospital or from outside.

20,974. Did not one of the doctors get plague?—Yes, that doctor was working in the hospital and his house was not situated in a very sanitary locality.

20,975. Do you disinfect floors in your hospital?—We have patent stone flooring now and we wash it with disinfectants frequently.

20,976. Do you disinfect the clothes of patients?—Yes.

20,977. How do you disinfect them?—They are dipped in sublimate, carbolic acid, or phenyle.

20,978. For how long?—For five or six hours in a solution of 1 in 1,000 of sublimate, and in 5 per cent. solution in the others. They are steamed according to the native fashion, and washed.

20,979. What is the temperature you get in your steaming apparatus?—It is over 200° Fahr., and the steaming is continued at this temperature for over an hour. The steam penetrates through all the clothing, &c.

20,980. Will you describe the steaming apparatus?—It consists of fire, with a shallow copper basin containing water, and there is a sort of plinth round about the vessel, which is fixed, and wet clothes are piled on the top to the height of two or three feet, and the whole is tied up with a big thick blanket so as to make it as airtight as possible. The fire is ignited underneath, and the steam passes through the wet clothes.

20,981. How far do you think the steam penetrates?—I do not think it penetrates very far. It is the native system which they have been using for ages past, and they have made no improvement in it.

20,982. Did you notice plague in inoculated people during that time?—I had only a few cases, and in them the disease seemed to take a very favourable turn.

20,983. How many cases did you see?—About 12, with one death.

20,984. Had these people certificates of inoculation?—They had; they generally came from institutions where all these records are kept. Some came from Sir David Sassoon's Reformatory, and some from other schools. In every case particulars were supplied with regard to previous inoculation.

20,985. Can you put in a table showing how long after the inoculation they got plague?—(The witness subsequently wrote as follows:—I regret that I am not able to furnish a table as desired, as it has not been possible to sort out all the charts. No case, however, was inoculated within six months of getting plague; in all cases the inoculation had been performed from 7 to 12 months before).

20,986. Have you had any experience of inoculation yourself?—No; I have done no inoculations.

20,987. I believe you admit the friends of patients to the hospital?—Yes

20,988. How many friends come in generally?—If the friends wish to attend on the patients we allow two, one for the night and one for the day. Visitors are allowed at all hours except during the visits of medical officers.

20,989. Do the friends of the patients get plague?—There was only case. The husband of a woman who was attending upon her got plague while in attendance on her. But that is the only case.

20,990. How long do the attendants stay in hospital?—Throughout the convalescence.

20,991. And they do not get plague?—No.

20,992. (*Mr. Cumine.*) Are the attendants allowed to sit and sleep on the floor?—They sit on the floor, and sometimes sleep there too.

20,993. (*Dr. Ruffer.*) You disinfect the floor, I understand?—Yes; formerly we had earthen floors, and new flooring has been put down lately.

20,994. (*The President.*) Had you had any cases among the attendants?—Only the one I have just mentioned.

20,995. (*Mr. Cumine.*) You used to pour down disinfectants pretty frequently?—Yes; phenyle or some powder: still, there was a lot of plague-infected material going into the ground and sinking into the floor.

20,996. Before the floor of the hospital was paved it was plain mud, was it not?—Ordinary earth.

20,997. Was there any cowdung upon it?—During the plague epidemic we had hardly time to cowdung the floor; it was cowdunged during the interval; but during the actual plague visitation it was not done, because that would have necessitated the patients being turned out, and that we could not do.

20,998. I wish to know whether the difference between the mud floor in your hospital and the mud floor in an ordinary native house is that the latter is cowdunged and yours is not cowdunged?—That is so, and also we use disinfectants in the hospital, which is not done in the case of ordinary houses.

20,999. (*Prof. Wright.*) Have you had any opportunity of testing Simond's theory, that plague is communicated by the bites of insects; have insects ever been very common in your hospital?—They are very plentiful, especially flies and mosquitoes, at this season.

21,000. Are the nurses and medical attendants bitten by fleas and bugs?—Certainly by fleas and mosquitoes.

21,001. Do you think that occurs to any great extent?—To a very great extent indeed.

21,002. You do not attach much importance to Simond's theory in view of that fact?—I do not.

21,003. You do not think that insects are very likely to carry infection?—The conditions are different in the hospital from those in the closed rooms of the houses; but so far as the hospital is concerned, the evidence points the other way.

21,004. How do you think the fleas in the hospital differ from those in private houses? Are fleas not continually passing from the patients to the medical officers?—The patients are more cleanly and we get rid of all their clothing, and I suppose most of the fleas and bugs would go too. But certainly the mosquitoes are there in very large numbers.

21,005. Have you formed an opinion that plague is less common in children than in adults?—No.

21,006. Have you seen any cases of coryza associated with plague?—No, nothing very marked. (Note added by witness on correcting proof of his evidence:—Some have been noticed since this evidence was recorded.)

21,007. Have you had any epidemic of pneumonia in the hospital; pneumonic cases which have infected other people there?—No.

21,008. Have you any rats in your hospital?—There are plenty of rats in the compound.

21,009. Have you noticed that these rats become infected with plague?—I have never seen a dead rat in the compound.

21,010. You have seen numbers of living rats?—Yes.

21,011. Do you know whether this is the experience in other hospitals?—I do not know that.

21,012. Do you think these hallucinations which you have described are all hallucinations of sight?—Of sight and sound, both.

21,013. Have you noticed that they are associated with a particular kind of headache?—Headache is always complained of, but nothing very marked to associate it with one form of hallucination or other.

21,014. Have you noticed that œdema occurs on the front chest immediately before death?—We find in axillary bubo there is sudden exudation, and the patient dies.

21,015. Have you seen any œdema in the chest when there was no axillary bubo?—No.

21,016. Have you ever seen what are called choleraic cases of plague?—No.

21,017. Do you think plague patients are made much worse when they are moved to the hospital during the course of their attack?—It all depends upon the state in which they are. I would not advocate the removal of a moribund patient, or one who is likely to die in a few hours; it would be of no use to the patient. I should say that the earlier the patient is brought to the hospital, the better chance he has of recovery.

21,018. You have not seen that treatment, independent of serum treatment, has any effect on the course of plague?—The only treatment which seems to have any effect is to keep up the state of circulation. Patients have been kept up for two, three, or four days simply by hypodermic injections of strychnine, strophanthus, and digitalis, where otherwise life would have ebbed away in a few hours.

21,019. (*The President.*) Did they ultimately recover?—No, most of them ultimately died; it is simply a question of doing all you can for the patient.

21,020. (*Prof. Wright.*) You have said that blisters occur in the course of the plague; do they occur in several regions of the body at once?—I have seen only two or three cases in which there were multiple blisters all over the body; they are generally single.

21,021. Those are secondary blisters; they are not associated with the source of infection?—The multiple blisters are secondary.

21,022. What about the single ones?—I think they are primary.

21,023. (*The President.*) With regard to these modified cases of plague, *pestis ambulans*, and *pestis minor*, do you know if they are infectious?—I do not think they are.

21,024. Have you any evidence one way or the other?—I have seen a number of cases—not in the hospital, but outside—in private practice, where they have occurred; and there have been no further cases in the same families.

21,025. Have you generally found pneumo-coccus in pneumonic cases?—In secondary pneumonia the pneumo-coccus was found along with plague bacilli.

21,026. In all the pneumonic cases of plague?—I do not think so; I have seen in primary pneumonic cases of plague only pure cultures of plague bacilli.

21,027. Pneumo-coccus does not occur?—That is so.

21,028. I understand that the impairment of articulation, to which you have referred, is very frequent?—It occurs in about 10 or 15 per cent. of cases.

21,029. It appears to be aphasia?—Yes.

21,030. Is there actual power of articulation or not?—I do not think there is any loss of actual power of articulation, because the patient understands fully what you say, and makes an effort to bring out what he ought to reply, but cannot say it; he might make a certain sound.

21,031. But not an articulate sound?—I do not think he can make any.

21,032. He understands what you say, and tries to say something in reply; but that something which he says is not intelligible?—Sometimes he cannot say anything at all.

21,033. With regard to the temperature which you describe, have you any temperature-curves which will illustrate your statement?—Yes, I can put in a chart.* There are a number of charts attached to the report† here which give the characteristics of the first temperature curves of the epidemic.

21,034. Have you any typical pulse-tracings?—Yes, I have a number of sphygmographic tracings‡ taken by Dr. Galeotti and Dr. Polverini.

21,035. How do you explain the pulse which you have described as being exactly the same as the pulse of aortic regurgitation?—The contractile power of the heart seems to be feeble, and the contraction is not able to expel the full quantity of blood which the ventrical contains; there is insufficient filling of the arteries.

21,036. I understand you to say that this pulse is like aortic regurgitation; do you know if there is actual regurgitation into the left ventrical?—I did not say actual regurgitation, but I saw it resemble it in this way, that the total quantity from the ventricals is not expelled and the arteries are insufficiently full.

21,037. In that case you would not have a large expansion of the artery?—That is so.

21,038. It ought to be a large expansion, ought it not—a large volume of blood projected into the artery?—The volume is much less than one would expect.

21,039. Then it is not a very typical aortic regurgitation pulse. Perhaps you will explain what you learn from the tracings?—Yes.‡

21,040. With regard to the occurrence of blood in the urine, you are quite satisfied that all these cases which you speak of as being cases of hæmaturia actually have blood corpuscles?—Yes; we have examined them and found it was not hæmoglobinuria, but hæmaturia.

21,041. (*Dr. Buffer.*) Could you tell us whether you have noticed any difference in the type of the diseases during these three epidemics?—I find the type of each succeeding epidemic becomes more severe; certainly the type at the present time is more severe than we have ever had.

21,042. Have you ever noticed a difference in the frefrequency of the lung symptoms?—They varied in different periods; at one period the lung symptoms are predominant, at others they are absent.

21,043. Is it so at present?—In the present epidemic the primary pneumonic cases were very frequent, but now we find they are very few.

21,044. Referring again to the cases of aphonia and aphasia, do you find that certain of those cases which, when spoken to, did not try to answer, did absolutely lose the power of even emitting sound?—Yes, they did.

21,045. (*Mr. Cumine.*) Are the cases of *pestis ambulans* confined to a particular season of the year?—No, they occur all through the epidemic, from its rise to its decline.

21,046. (*Prof. Wright.*) Do you find that the severity of the cases goes down towards the end of the epidemic?—Yes, it does.

21,047. You get a larger percentage of recoveries?—Yes.

21,048. (*The President.*) How is relapsing fever modified when it occurs in plague?—I should say that plague is modified by relapsing fever, and the way in which this occurs is very curious. The patient is brought in with all the symptoms of plague, and with bubo; the temperature runs a regular plague course for three or four days, and perhaps remains persistent up to the sixth day, and then we find a sudden drop exactly as in relapsing fever; after the bubo is incised the patient proceeds into convalescence. Then there is an interval between the fall of temperature and relapse. I have at present two or three cases in the hospital which are very typical of that.

21,049. Perhaps you will include these among your charts?—Yes*; *vice versâ* a patient comes in who has relapsing fever with no bubo, and during the apyrexial stage he develops femoral or inguinal bubo and seems to go through an attack of plague. Plague seems to be considerably modified by relapsing fever.

21,050. Then you say pyrexia occurs at a stage when it should have occurred in relapsing fever and not when it usually occurs in plague?—That is so. I should like to put in a statement with regard to the details of the various series of cases treated with Prof. Lustig's serum, as follows:—

TABLE showing the DETAILS of the various SERIES of CASES treated with Professor LUSTIG'S SERUM in 1898.

Months, 1898.	Series.	Horse No.	No. of Patients treated.	Died.	Recorded.	Percentage of Recoveries.

May and July	10	3rd „	16	6	10	
September	14	5th „	10	3	7	
Total	—	—	70	32	38	54·28
		IV.				
April	3	1st bleeding	8	3	5	
May	7	2nd „	11	5	6	
July and August	11	3rd „	12	6	6	
October	17	5th „	12	6	6	
Total	—	—	43	20	23	53·48
		V.				
October	18	1st bleeding	12	8	4	
Total	—	—	12	8	4	33·33
Grand total	—	—	257	145	112	56·42

There is one point I should like to mention. Three years' experiences at the Hospital gives us an average mortality of 71·44 per cent. The following figures may be of interest to the Commission:—

TOTAL PATIENTS TREATED at the ARTHUR ROAD HOSPITAL up to end of January 1899.

3,919—died—2,800	71·44 per cent.
Died within 24 hours	29·36 „
Died within 48 hours	18·01 „
	47·37 „
Recovered under ordinary treatment	28·56 „
	75·93 „
Remain which could be influenced by serum	24·07 „
	100·00 „

From these 24·07 per cent. eliminate some that must die after 48 hours, others succumbing either through sudden heart failure, complications, pyæmia, intercurrent diseases, &c., say, about 10·07 per cent., thus leaving only 14·00 per cent. who could be pulled through by the serum.

21,051. (*Mr. Hewett.*) How many die in the first 24 hours?—About 30 per cent., and about 19 or 20 per cent. in the following 24 hours.

21,052. (*Dr. Ruffer.*) Unless you got a serum which acted immediately?—I should say that all these cases were past all hope; they could not possibly be saved except by a miracle.

(Witness withdrew.)

(Adjourned till to-morrow at Poona.)

At The Council Hall, Poona.

FIFTY-FOURTH DAY.

Thursday, 23rd February 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Capt J. B. Smith, I.M.S.

23 Feb. 1899.

Captain J. B. SMITH, I.M.S., called and examined.

21,053. (*The President.*) You are in the Indian Medical Service?—Yes.

21,054. What are your medical qualifications?—M.B., M.C.H., and I am also Bachelor of Arts.

21,055. You are also the Civil Surgeon here?—No, I am the Assistant Civil Surgeon.

21,056. You are prepared to give evidence in regard to Karad, I understand?—Yes.

21,057. In the first place, would you tell us how plague originated at Karad?—As far as it is known it was an epidemic that was concealed.

21,058. Can you give us the history of its origin?—In the end of January and the beginning of February 1897, Mr. Young, one of the Survey Department, reported that there were about 13 or 14 cases in the Karad taluka. From that onwards nothing particular happened till the month of March, when the death-rate began to go up. The average death-rate for five years for the town of Karad was 21. The death-rate rose in March to 30, in April it rose to 40, in May it rose to 108, and in June it apparently fell to 52. Major Baker, I.M.S., who was the Plague Supervising Officer, thinks it was due to concealment. In July it rose to 230, in August there were 730 deaths, in September 313, and then it fell in October to 62, in November to 29, and in December to 26.

21,059. What is the normal population of this town?—About 12,000.

21,060. Did you ascertain how plague originated in the town?—No. It was concealed for two months, and it was not notified as plague till the 7th of July. On the 1st of May cholera was notified in the town, and most Medical Officers who have had anything to do with Karad have come to the conclusion that it was not cholera but really plague.

21,061. There was no special means of ascertaining what caused the people to die at that time?—No, except the ordinary Municipal register.

21,062. There was no inspection of corpses?—No, not at that time.

21,063. Having ascertained that there was plague, what did you do?—Before I went there, a Plague Flying Column was sent there on the 13th of July. I did not go there until the 2nd of September, when the epidemic was at its height.

21,064. What had been done before you went?—Search parties were instituted of the ordinary character, and corpse inspection was started. Patients were removed to hospital and their friends were segregated, but no evacuation was carried out.

21,065. By friends, do you mean contacts in general?—Yes.

21,066. There was a special difficulty, you think in the diagnosis of the earlier cases. What was that due to?—It seems to me that very possibly the earlier cases were not bubonic.

21,067. On what grounds?—I have no grounds; it is a hypothesis. I will give you the reason for it afterwards. In the taluka, in the villages round Karad, where plague was in an earlier stage than in Karad, the cases were very largely non-bubonic, so that one would assume it was possibly the same in Karad itself. In several villages I afterwards heard that the earlier cases were non-bubonic. In one village, called Kesa, the earlier cases were always non-bubonic,

21,068. How were these cases known to be plague cases at all?—From their general resemblance to plague—the plague countenance, and the eyes.

21,069. You have seen such cases?—Yes.

21,070. Will you state the grounds on which you came to the conclusion that they were plague cases?—They have absolutely the same appearance as a plague patient, except that there were no buboes—the suffused eyes, peculiar tongue, the stupid expression of the face, the high temperature, and the hot burning skin, and their rapidly fatal termination.

21,071. What is this peculiarity about the tongue?—It is a tongue whitish in the centre, with red edges and tip.

21,072. You are arguing by analogy?—Yes, because probably nobody knows what actually did take place in Karad at first.

21,073. After you came on duty, were the measures extended in any direction?—The measures were very largely extended. The staff of the Plague Column was considerably increased. A large number of coolies were imported from Bombay, some European Inspectors were sent, and also another doctor.

21,074. That is in regard to the staff, but as to the measures themselves, what was the extension?—The only extension was that they were made more perfect. No extra measures were taken; the measures previously in existence were carried out more perfectly.

21,075. Did you ever adopt evacuation on a larger scale than you have described?—No, not in Karad town.

21,076. It was only partial evacuation?—We had no evacuation.

21,077. Only the actually affected people and the contracts were segregated?—Yes. It was in the middle of the rains, and it was extremely difficult. The whole trade of the place was paralysed, and it was practically impossible to get accommodation for the people. We had the greatest trouble in getting accommodation for the ordinary segregation and observation camps.

21,078. In those houses where the inmates had been removed as you have described, what measures did you adopt?—We disinfected them with perchloride of mercury, we opened the roofs, and made large holes in the roofs all along the ridge of the pole, two feet on either side; I took off all the tiles and all the matting underneath, and exposed them to the air and then disinfected them with perchloride spray.

21,079. How long were they left unoccupied?—They were certainly left unoccupied for ten days, the period during which the people were segregated; in the majority of cases they were left longer.

21,080. When re-occupied, did any plague cases occur in these houses?—Not to my knowledge.

21,081. Do you mean that you have no knowledge?—I mean that I should probably have heard of any case. I should have known of any case if it had occurred. There was a case afterwards, in the general disinfection of the town.

21,082. There was a further measure then; what was that measure?—Yes. We did not know what houses were affected in the first instance, and so we commenced at one end of the town, and disinfected right on to the other end.

21,083. About how many houses would that represent?—We disinfected altogether about 2,200 houses before I left, and they were still at it.

21,084. What happened to the inmates of these houses while they were being disinfected?—The inmates had to live in their own verandahs; there was no accommodation for them elsewhere. They refused to go to the segregation camp.

21,085. Were the clothes, and everything in the houses, disinfected?—Everything was disinfected, except things that would be ruined by the perchloride.

21,086. Clothes also?—Yes.

21,087. How was that done?—By perchloride; we steeped everything in perchloride, except woollen and leather goods, which were put out in the sun.

21,088. What was the general result of these measures in so far as the progress of plague was concerned?—The plague went down very rapidly. Here is a chart showing the course of the epidemic. (The witness handed in two charts).*

21,089. In what particular does it show it?—When the measures became effective, the plague mortality and the plague attacks went down. About August the 23th, Major Baker visited the place and got an extra staff, and things were put on a better basis, and from that onwards the death-rate went down, and the attacks went down.

21,090. You had commenced these measures in August?—They were commenced at the end of July first, and they were put on a better basis in the beginning of September. The plague broke out in July, and the plague measures really only began about the end of July. The Plague Column arrived there in July.

21,091. The plague continued to increase?—Yes, until the very end of August.

21,092. While these measures were being carried out?—They were being carried out in an ineffective way.

21,093. Will you describe the difference between ineffective and effective in this case? What do you mean by effective in one instance and ineffective in the other? What was the difference?—Everything was done more thoroughly after the beginning of September. In disinfection, at first, they had too small a number of coolies to overtake the houses infected; after that we got enough coolies to keep pace with the epidemic as it went along. The houses were disinfected within one or two days after they were infected.

21,094. When that was done thoroughly, you think the epidemic began to fall?—It began to fall, but whether it was a coincidence or not, I cannot say.

21,095. Did you find much difficulty in carrying out disinfection thoroughly?—I had the greatest difficulty, extreme difficulty.

21,096. What kind of difficulties?—Unless you are constantly present with your coolies, they have a tendency to shirk their work, partly through laziness and partly through corruption.

21,097. Is there any special difficulty in villages; you refer to that in your précis?—The difficulty of providing European supervision. Unless disinfection is done with European supervision, I do not think it is much good, because these coolies, if you do not watch them continuously, get very careless.

21,098. What kinds of floors had the houses you were dealing with?—Earthen and cow-dung floors.

21,099. Did you do anything more than apply perchloride or other disinfectant solutions to these floors?—No; the floors were not touched, except to soak them with perchloride solution.

21,100. The walls and the ceilings also?—The walls, and the ceilings, the floors, the furniture, and everything was taken out of the house that could be removed, and before returning, they are put through solution.

21,101. What did you regard as the chief channel of infection?—I cannot give any opinion on that.

21,102. Have you any idea as to any channels of infection; how is the plague communicated from one person to another?—It seems to be a local infection of the house, but I had no leisure at the time to follow up the cases one by one.

* *See* App. No. LXVI. A, and B, in this Volume.

Capt. J. B. Smith, I.M.S.
3 Feb. 1899.

21,103. You have no instances in which it seemed to be conveyed, for example, by one person to another?—No. I had one instance where it seemed to be conveyed by furniture, but as the people were related to one another, of course there is a flaw in the argument The family got plague in the house before disinfection. After the people had been taken to the hospital they sent some of their furniture to a brother-in-law's house and in about four or five days some people in this house got plague. But then that may not have been by the furniture, as they were nearly related.

21,104. They may have come into personal contact with one another?—Yes. That is the only instance I know of communication by furniture apparently.

21,105. Have you any instance as to the conveyance by animals of the infecting virus?—No, all the rats were dead at the time I got there.

21,106. You had some experience with Yersin's curative serum?—Yes.

21,107. Would you detail that experience?—There are 32 cases treated. I propose to hand in a statement showing the details.

21,108. Perhaps you will summarise them?—There are 32 cases treated, and of those 21 died. There were two cases which were doubtful as to whether they were plague or not, and two were very mild cases.

21,109. These recovered?—Yes. The statement is as follows:—

STATEMENT of CURATIVE INOCULATIONS performed by DR. SIMOND, at KARAD, with M. YERSIN'S SERUM.

Serial No.	Register No.	Names.	Age.	Sex.	Caste.	Street.	Date of Admission.	Date of Death.	Date of Discharge.	Dr. Simond's Notes.
1	639	Chandra Subhana	9	Female child.	Mahratta	Mangalwar Pet.	5.9.97	7.9.97	—	Bubon inguinal droit et pneumonie 2e jour de la maladie, cas très grave, 40cc. sérum en 2 fois.
2	638	Datto Ram Krishna	7	Male child.	„	Somwar Pet.	„	5.9.97	—	Bubon axillaire et pneumonie à droit 2e jour de la maladie, cas très grave, 15cc. de sérum injecté 6h. avant la mort.
3	639	Krishna Mahadéo	32	Male	„	„	„	6.9.97	—	Bubon inguinal droit parotide embarrassée, 2e jour, cas très grave, 60cc. de sérum en 2 fois.
4	643	Shita Kom Pandoo	25	Female	„	Karad	6.9.97	8.9.97	—	Bubon axillaire et bubon cervical 3e jour de la maladie, cas très grave, 60cc. sérum en 2 fois.
5	649	Dhond Bhat Manikhat	50	Male	Brahman	Guruwar Pet.	„	9.9.97	—	Pneumonie double, pas de bubons, 2e jour de la maladie, cas très grave, 90cc. sérum en 4 fois.

21,110. (*Dr. Ruffer.*) Where was the serum used?—In Karad town.

21,111. (*The President.*) Was it used in the hospital?—Yes.

21,112. Did you apply it?—No. Dr. Simond applied it.

21,113. Do you know the details?—More or less.

21,114. Do you know what dose was given?—The dose is all given in the statement, which also gives Dr. Simond's own notes on the subject.

21,115. What was the general result in your opinion?—That it was ineffective, and of no use.

21,116. What was the mortality?—The mortality was as bad (65·6 per cent.) as the average hospital mortality.

21,117. The mortality was greater than the average hospital mortality?—Dr. Simond's cases were, perhaps, better diagnosed than our general Plague Hospital statistics. I should say the mortality rates were about the same.

21,118. Have you had some experience of prophylactic treatment?—Yes. I have very little experience about Haffkine's. In Karad town and the districts we did 136 cases altogether, and so far as I know none of those people got plague.

21,119. You guard yourself; have you not been able to follow the history of these persons?—The ones in Karad up to the time I left had not got plague. I know about 101 up to the time I left Karad that had not got plague.

21,120. How long after inoculation would that be?—A varying period; some were inoculated a fortnight before I went away, and some were inoculated very much earlier than that.

21,121. How much? What was the longest interval and what was the shortest?—I should say about a month and a half or two months, probably. Of course we commenced inoculating at the time when plague was practically over in Karad.

21,122. This was the period of the fall of the plague?—Yes, at the end of the plague.

21,123. About when was that?—About the middle of November the death-rate in the town was down to normal. The reason these people were inoculated was that they wanted to go out into the infected villages for trading purposes. Sixty-one people got inoculated on that ground.

21,124. What is your opinion of the value of that evidence as showing whether there was any protection produced or not?—I should think, as there were 61 people who went backwards and forwards to infected villages, they stood a very good chance of getting plague if they had not been inoculated.

21,125. Are you aware of any number of people who were not inoculated, who also went backwards and forwards between the villages?—You will see them marked in the upper chart.* Those cases that occurred, the imported cases, were amongst the uninoculated people who went backwards and forwards.

21,126. Do they represent a larger proportion than those actually inoculated?—I should say they represented about the same.

21,127. (*Mr. Hewett.*) I do not know whether you stated the population of Karad?—It was about 12,000 in 1886.

21,128. Was there an Assistant Surgeon there when plague broke out?—There was a Hospital Assistant.

21,129. I suppose he had not had any previous opportunity of seeing a case of plague?—No.

21,130. Apparently plague went on till the end of January 1898?—Dropping cases, yes. Most of them were imported as you will see by the upper chart.*

21,131. I see that the curve goes up and down almost evenly. The epidemic went up to a certain point, and then down again. The descending line is very like

* *See* App. No. LXVI. A in this Volume.

Capt. J. B. Smith, I.M.S.

23 Feb. 1899.

the ascending line. Do you think that this indicates that the suppression of the epidemic was clearly due to the measures taken?—Only this, that when measures began to be very thorough the epidemic began to go down; it is a coincidence.

21,132. When do you think that the measures began to be done very thoroughly?—I should say about a week after I went there.

21,133. When was that?—I went there on September the 2nd.

21,134. The plague had already begun to decline?—It had, but Major Baker had been there before me, and he had the searching done more thoroughly.

21,135. When did he go there?—On the 26th of August. A slight decline took place at once.

21,136. But starting from the week ending the 28th of August which was the week of the maximum number of attacks there were 518 attacks in the four preceding weeks, and 479 in the four succeeding weeks; do you think those facts show that it was the measures that caused the epidemic to decline?—All I can say is that it is a coincidence, if they have nothing to do with it.

21,137. Would you expect that the decline would be more rapid if it was the result of the measures taken?—No, I do not think so.

21,138. What is the particular measure to which you attribute the decline of the epidemic at Karad?—I consider disinfection had the great effect, and taking the contacts out of their houses.

21,139. Have any of the houses which were disinfected in Karad become re-infected?—They have within the last month or two.

21,140. Have you been able to trace this re-infection to people coming from other places?—I have nothing to do with Karad now, but I have been told by people on the spot that they have been infected by people in the Pathan taluka.

21,141. Does your experience at Karad show, in your opinion, that in order to suppress an epidemic of plague, it is not necessary to insist upon evacuation of the place?—If I have to go back to Karad, and at a suitable time of the year, I should prefer evacuation.

21,142. On what ground?—On the ground of the effect it had in villages. People were turned out of the villages by executive order, as soon as the rains had subsided, and the death rate went down very rapidly.

21,143. (*The President.*) I understood you to say you had no experience of complete evacuation?—That was in charge of the Medical Officer who actually did the work, and I only dealt with the subject as his superior officer. He is at home now, so he cannot be called.

21,144. (*Mr. Hewett.*) Were these villages evacuated during the rains?—They were evacuated immediately after the rains. They were evacuated partly by the will of the people themselves. As soon as the rains ceased they went out into their fields.

21,145. Do not you think that evacuation on black cotton soil is very difficult to effect during the rains?—That was the difficulty in dealing with the people in Karad and the villages during the rains; it was impossible to do it.

21,146. When you evacuated these villages after the rains were the people whom you turned out allowed to go where they liked?—They were in most villages.

21,147. Do you think that was a good plan?—I think there is a great risk of their going to other villages.

21,148. But you think it is a good thing to get them out of the infected site?—Yes. There are two kinds of villages that one must take into account; agricultural villages, and commercial villages. The agricultural villagers are not likely to leave their village, they are accustomed to go out and live in their fields in the cold weather, and in the dry season, and they have no particular object in going off to other villages; whereas in commercial villages weavers, for instance, cannot carry on their trade in the fields, and they must go to some place where they can get a house.

21,149. Does that chart* show the results of the evacuation of these villages?—I think so. One shows the rainfall, and the other the course of the epidemic. You must make allowance in these charts, however, for the fact that the returns are made by the village officers, who are very slow in sending in their information with regard to plague. But as soon as the rain ceased the epidemic went down, in about three weeks I think.

21,150. Did you observe any instance in which a village having been evacuated, because a particular portion of it was infected, the inhabitants, on returning to the village, got plague in other portions of it?—I think, as a matter of fact, the whole of the village was evacuated. The Second Assistant Collector, who was the Chief Plague Authority, issued an order that they were to clear out, and they did, into the fields. There was no partial evacuation at all.

21,151. I was asking about what happened when the people were allowed to go back to their villages?—I was not there then.

21,152. Were the villages entirely disinfected?—They were supposed to be.

21,153. Did not you find that a difficult process in a village?—Yes, it is almost impossible in the villages.

21,154. Why?—Because you have to trust to people of a very low social scale who are very open to bribes, and who in many cases are careless about the process, and think that things are of no importance which might really be of great importance.

21,155. Do you think that it is essential to disinfect the roof of a house?—That I am not in a position to say. I am not a bacteriologist.

21,156. Do you think that it is possible to disinfect the roof of an ordinary house in a village?—I do not think it is possible to do it thoroughly; I am almost certain it is not. What I should propose to do in a village, as soon as a plague case is reported, is to have the house in which it occurred immediately unroofed. In a village you have not any police, as a rule, except the ordinary village police, and it is impossible to make certain that the people do clear out of the infected houses. But if you take the roof off, I do not think it matters very much whether the people live in the house or not; they would have lots of fresh air and sunlight.

21,157. Do you know whether the villages which were infected in Satara in 1897, have become re-infected now?—As a matter of fact I do not think they have ever been absolutely free since.

21,158. (*The President.*) Were those villages evacuated?—Yes.

21,159. (*Dr. Ruffer.*) Can you point out on this chart the day when the evacuation took place?—I am sorry I cannot give you the order, but as soon as the rains were over the people began to clear out at once, partly of themselves to attend to the cultivation of their fields.

21,160. Looking at this chart it would appear that 10 weeks elapsed before the disease disappeared?—Yes, but it went down with a run. The fair weather began in the week ending November the 6th.

21,161. When did the disease almost disappear?—The lowest figures are for January the 15th.

21,162. How many weeks is that?—Ten weeks.

21,163. How long did it take in the village where no evacuation took place?—Seven weeks.

21,164. That is seven weeks as contrasted with 10?—Yes.

21,165. What then is the benefit of evacuation?—It is possible to carry it out effectively, while it is not possible in villages to carry out disinfection.

21,166. You said you stopped the epidemic quicker by evacuation, but, in this case, the epidemic seems to have stopped quicker by disinfection?—I believe you can improve upon that by adding evacuation to disinfection.

21,167. Why do you think so?—Because you have the people absolutely away from the infected site.

21,168. But in the infected villages it took a longer time?—As I told you, it took some time for the people to clear out, to make certain that the rains had stopped. Those are the weeks that are reported at the Mamlutdar's office, and it takes the village officers a certain amount of time to send them in. They are very slow in sending in a document of that kind, so you must allow those returns to represent, I should think, two weeks earlier.

21,169. You saw the cases treated by Dr. Simond?—Yes.

* *See* App. No. LXVI. B in this Volume.

21,170. I see he mentions two cases of intestinal plague. Have you any experience of that form of plague?—No, not except what he has there. I should have called that the ordinary non-bubonic form.

21,171. Septicæmic plague?—Yes, septicæmic plague.

21,172. Have you ever seen a case of what you might call intestinal plague, where the intestinal lesions were very clearly marked?—No, I cannot say that I have.

21,173. Have you any experience of plague *post mortem*?—No.

21,174. (*Prof. Wright.*) What inducement has a villager to offer bribes to a disinfecting coolie?—To save his kit being put into perchloride solution.

21,175. Does that spoil the clothes?—It does not spoil cotton clothes, but it spoils woollen clothes, and it spoils leather.

21,176. (*The President.*) In those villages that you have referred to, what was the time occupied in effecting evacuation?—That I could not tell you. It was left to the village officers to turn the people out, and in some villages they would be quick, and in others slow. It was done simply by an order of the Second Assistant Collector, and issued to village officers.

21,177. You have no personal knowledge?—No.

21,178. How do you know they were ever entirely evacuated?—I heard it from the Medical Officer who was under me, and from the Assistant Collector.

21,179. So far as you know, how long did it take?—I would rather not answer that question; I do not know.

21,180. It may have been a very long time or a very short time?—I should think it was within a fortnight in all cases, perhaps less.

21,181. What means were taken to prevent evacuated persons from returning to the houses in the village or villages?—The village officers were supposed to prevent that, and that is the weakness of the system; you have to trust so much to village officers in these matters.

21,182. You do not think that is an effective method of preventing the return; you think they probably did come back?—It is not an effective measure, and I think that people probably did come back every now and then. They would give a rupee or so to the village officer and go back for kit, or to stay in the house.

21,183. You cannot present these as a model example of evacuations; there were a great many flaws in the process?—No, I do not present them as a model example. There were a great many flaws. There were no means to prevent the people going to other villages, which is a very great flaw, in my opinion. There was one village which was taken in hand by Dr. Robertson. He passed all the people out of the village through an observation camp, and allowed them to go anywhere. He then got all the village disinfected, and he brought them in again in the same way through the observation camp, and that village remained uninfected and I believe it is still uninfected.

21,184. You think that plague was stopped in the first case?—Yes, and so far as I know, it has not occurred again in that village.

21,185. Within that time, was it stopped among the evacuated?—I think there was only one or two cases among the evacuated altogether.

21,186. Have you got any figures?—I cannot give any figures. This was a year and a half ago, and I am now away from my office, and I have no means of procuring those figures.

21,187. You have no access to the records?—No.

(Witness withdrew.)

Lieut.-Col. W. J. Fawcett, R.A.M.C., called and examined.

21,188. (*The President.*) You are in the Royal Army Medical Corps?—Yes.

21,189. And you can give us evidence about Poona and Kirki?—About Poona and Kirki cantonments, and the suburban Municipality from the commencement of work by the Committee formed by Government under the Presidency of General Duncan, on the 17th November 1897 up to August last, when I left the Committee. But plague had ceased in the portions of the country under our control about the 11th of March, which was the date of the last case.

21,190. (*Dr. Ruffer.*) Could you tell us what the population of the Poona cantonment was at the beginning of the plague epidemic?—It was believed to be between 25,000 and 30,000 people.

21,191. When was the last census taken?—That I could not say. The above was the information I received at the time.

21,192. What was the population in Kirki cantonment?—The cantonment bazar about 2,000, and the followers of the Royal Artillery 1,700; but that is merely a rough guess.

21,193. Plague appeared first in the Poona cantonment on the 27th of June, did it not?—Yes.

21,194. There are two cases among the followers of the 2nd Bombay Lancers?—Those were the first recorded cases.

21,195. Have you any reason to believe that there was plague before that?—I was not present at the time. I fancy it is very probable that there were cases of plague before that.

21,196. Why?—From what I have seen of the difficulty of diagnosing first cases of plague.

21,197. You say in your précis of evidence, "On the 2nd of July a sawar was attacked." What is a sawar?—A sawar is a trooper of a Native Cavalry regiment.

21,198. On the 4th there were three cases, on the 5th, one child, and on the 6th, two sawars and two children, all in the 2nd Bombay Lancers?—Yes.

21,199. You have been told that the disease "had been imported with grain purchased by the regiment in Bombay." Could you give us any evidence as to that?—Not the slightest evidence. It is contained in a Report* made by the late General Duncan, and when writing the report on plague in Poona I did not feel myself justified in altering it in any particular. I do not hold myself responsible for that statement. At the time it met with general approval.

21,200. (*The President.*) Does that apply to the whole of this Report*?—Not to the whole of it, only to the first five pages. The foregoing is a statement with which I do not agree. I see no grounds for agreeing with it.

21,201. (*Dr. Ruffer.*) Why not?—My experience of plague leads me to believe that it is not at all probable that grain will carry the germ of plague for any considerable length of time.

21,202. In this particular instance?—In this particular instance I know that plague existed in the villages around the cantonments, although I cannot prove it, before June. I know it from my experience in talking to the villagers, and in the bazars afterwards, that there was plague in the surrounding country before that.

21,203. Then the plague spread to other squadrons of Cavalry in the cantonments, did it not?—In the Cavalry lines in the cantonment, yes.

21,204. Can you tell us when the first cases occurred in the chawls in the borders of the lines?—I could not. I was not present.

21,205. Have you any evidence to show that there were cases in the chawls before the regiment was attacked?—None whatsoever.

21,206. Could you tell us whether there had been plague in the Kirki bazar during that time?—There were no cases in June. In July there were cases in the bazar in Kirki. There had been three cases in May, but none reported in June.

21,207. Do you think that these were really the first cases, or only the first cases that were noticed?—I think they were the first cases that were noticed, but that must be a matter of opinion.

* "Report on Plague in Poona and Kirki cantonments and suburban limits from 17th March 1897 to 19th March 1898," by Lt.-Col. W. J. Fawcett, not reprinted with the Proceedings of the Commission. The opening portion of this report had been written by Lt.-Gen. J. Duncan.

Lieut.-Col. W. J. Fawcett, R.A.M.C.

23 Feb. 1898.

21,208. On the 7th August disease broke out in the Royal Artillery followers' lines?—Yes.

21,209. And these followers were moved block by block into the health camps?—Yes.

21,210. Were the lines disinfected?—They were disinfected; at least, it is reported so.

21,211. How?—By the use of perchloride of mercury, I understand.

21,212. You did not do it yourself?—I was not there at the time.

21,213. Did any cases of plague re-occur when the regiment went back to those lines?—In Kirki. I think it would be better for me not to answer that definitely because I was not there, and the records kept at the time were extremely confused, and any information I could give you that I derived from records would be practically worthless with regard to that portion of the epidemic in Kirki about the re-infection.

21,214. Why do you think it is worthless?—I have seen the records, and I have conversed with men who were working at the time before the appointment of Major Temple. They were overworked; it was raining night and day, and there was a scene of confusion; there were not sufficient hands and there were not sufficient heads.

21,215. Major Temple assumed charge on the 20th of August?—Yes.

21,216. Can you tell us what measures he enforced?—He commenced by instituting search parties, which were very carefully carried out indeed, that is to say, I think from the time he commenced work it would have been impossible to conceal a case within the limits of the cantonment. The bazar at that time was almost deserted; instead of containing 2,000 there was not probably more than 600 people in it; the lines were being evacuated at the time.

21,217. What had become of the 4,000 people?—The other 1,600 people. There were 2,000 inhabitants of the bazar alone who fled here and there throughout the country—melted away. It would be almost impossible for a case of plague to exist for 24 hours without being discovered under Major Temple's arrangements. On discovery of a case it was at once sent to the hospital, the whole of the inhabitants of the house were at once placed in segregation camp, and the house immediately disinfected with very elaborate disinfecting arrangements—quite a toilet—and I think that constitutes practically the whole of his arrangements.

21,218. The houses were disinfected with perchloride of mercury?—Yes.

21,219. How long did the people remain in segregation camp?—10 days.

21,220. They were then allowed to go back to their houses?—Yes.

21,221. When were the last cases of plague under this system in Poona cantonment?—The last case of plague occurred on the 11th of March, but practically the last indigenous case occurred in Poona cantonment about the 28th or 29th of December.

21,222. The epidemic in Kirki was practically at an end in September, was it not?—Yes.

21,223. Did the neighbouring villages get infected?—All the villages in the immediate neighbourhood were infected.

21,224. How many?—There were practically only two near Kirki, and they were both infected.

21,225. What were the names of the villages?—They are two small villages near the cantonments; their names are not given on the map I have.

21,226. There was some plague among the Royal Artillery followers in Kirki, was there not?—Yes, there was very severe plague indeed amongst them.

21,227. How many followers are there, and how many died?—There are about 1,700 followers, but the number that died is uncertain. The families are continually varying in numbers.

21,228. In August there was a total of 181 cases and 80 deaths among the followers?—Yes.

21,229. Did you perform any inoculations among the followers?—Inoculations were performed.

21,230. When?—That I cannot tell you. I have seen the records, and I had hoped to lay the particulars before the Commission, but I regret to say that the records are valueless. The only Medical Officer there was was overworked at the time. He inoculated the people it is true, and he endeavoured to follow the course of the life-history of those people afterwards, but the results he arrived at are so widely different from those arrived at by other people that I decline to produce them.

21,231. How many did he inoculate? Does he know that?—No.

21,232. Does he know how many deaths occurred amongst those who were known to be inoculated?—I have not got the records with me, and I can only say that it was impossible to arrive at any exact conclusion. There were numbers of pieces of paper with the same names repeated.

21,233. So that you think the whole of the figures are valueless?—Yes. I think the figures are valueless. The conclusions are different from those arrived at by Prof. Haffkine. They are valueless in my opinion.

21,234. Could you give us the figures as they are?—I can ask for the records, and bring them if you wish. They are not in my possession at present.

21,235. In whose possession are they?—They are in the possession of the Deputy Assistant Adjutant-General of the Poona District.

21,236. Can you give us any information about the Bombay Sappers and Miners in Kirki?—The Sappers and Miners were not infected until much later than the followers of the Royal Artillery. Their lines are situated on the other side of the river. They had dropping cases amongst them.

21,237. What is the number of the Bombay Sappers and Miners?—I could not actually say; I should think about 700.

21,238. They had three men, two women, and six children attacked, had they not?—Yes.

21,239. Eleven cases and nine deaths?—Yes.

21,240. Were any inoculations performed among the Bombay Sappers and Miners?—No.

21,241. When were the Bombay Pioneers attacked?—The 28th Bombay Pioneers were also attacked in October, and the last case occurred on the 26th of December. Seven men, nine women, and seven children suffered. There were 20 deaths.

21,242. Were the Royal Artillery followers or the native troops sent out of their lines, or did they remain in their lines?—The Sappers and Miners and the 28th Bombay Pioneers were camped out. They had a few cases among them. The result was eminently beneficial. Three cases occurred among the 28th Bombay Pioneers after they were camped out.

21,243. How many cases had they had before?—Seven men, nine women, and seven children; and deduct three patients from the total.

21,244. How many cases were there among the Bombay Sappers and Miners?—Only two cases occurred after they went out. One of those was a man who was engaged in whitewashing in the infected lines.

21,245. How soon after evacuation did these three cases of plague occur?—As regards the depôt of the 28th Pioneers—the camp was formed on the 28th October 1897. Cases after 1st November 1897 occurred as follows: one soldier on the 12th November; one Banniah on the 23rd November, and one soldier on the 25th December. As regards the Bombay Sappers and Miners—the camp was formed on the 7th January 1898. One case occurred on the 7th January and one on the 22nd January.

21,246. You had a Plague Hospital in Kirki, had you not?—Yes.

21,247. We will now return to the Poona Cantonment. Poona Cantonment was re-infected on the 9th of August, was it not?—Yes, it was said to be re-infected then.

21,248. It was supposed to have been re-infected from Kirki, was it not?—Supposed to have been.

21,249. Do you think it was actually re-infected, or do you think plague has been going on?—I have no doubt it was re-infected. I fancy that there were dropping cases of plague in the supposed interval between May and August.

21,250. In the interval between May and August was there anything like corpse inspection or search parties?—I was not here at the time, and I am not quite certain whether there was corpse inspection or not. My personal experience only began late in October.

21,251. Can you tell us anything about plague among the troops, Native or otherwise, in the cantonment?—The disease first attacked the troops in cantonment on 28th September; on that date two cases occurred in the 19th Bombay Infantry; on 29th another case occurred in the same regiment, and six in the 2nd Grenadiers; prior to this, however, there had been some cases in the bazar of the 2nd Grenadiers, quite a village, being very much overgrown and overcrowded. On this date, 29th September, both regiments were moved into camp on the Poona Racecourse. As cases continued to occur after these regiments moved into camp, the camp of the 19th Bombay Infantry was moved on to the top of Gibbet Hill on 15th October, and that of 2nd Grenadiers to the foot of Gibbet Hill on 23rd October; three cases having occurred in the lines of the depôt of 14th Bombay Infantry, on 27th October they likewise were moved into camp on Gibbet Hill.

21,252. How many cases occurred after these regiments were removed into camp, and what were the dates of the recrudescence of each case?—The particulars are as follows:—

2nd Bombay Grenadiers. Encamped on Racecourse, 29th September, 1897.

1st October	- -	One case in a child.
3rd ,,	- -	,, ,, woman.
3rd ,,	- -	,, ,, child.
10th ,,	- - -	,, ,, boy.
13th ,,	- -	,, ,, follower.
18th ,,	- - -	,, ,, ,,
21st ,,	- -	Four cases in soldiers.
22nd ,,	- - -	One case in a woman.

Camp moved 23rd October.

14th November	- -	One case in a soldier.
15th ,,	- -	,, ,, woman.

Depôt 14th Bombay Native Infantry. Encamped on the 28th October, 1897.

5th November	- -	One case in a child.
5th ,,	- - -	,, ,, follower.
6th ,,	- -	,, ,, child.
10th ,,	- - -	,, ,, ,,
18th ,,	- -	,, ,, woman.

Camp moved further from cantonments.

19th Bombay Native Infantry. Encamped on Racecourse, 29th September, 1897.

30th September	- - - 2 soldiers.
1st October	- - - 3 ,,
2nd ,,	- - - - 1 woman.
3rd ,,	- - - - 1 soldier.
3rd ,,	- - - - 1 woman.
7th ,,	- - - - 1 child.
11th ,,	- - - - 1 soldier.
12th ,,	- - - - 1 ,,
12th ,,	- - - 1 woman.
13th ,,	- - - - 1 soldier.
13th ,,	- - - 2 women.
13th ,,	- - - 2 children.
14th ,,	- - - - 1 soldier.
14th ,,	- - - - 1 woman.

Camp moved 15th October, 1897.

15th October	- - - 1 follower.
17th ,,	- - - 1 soldier.
21st ,,	- - - - 1 ,,
22nd ,,	- - - 1 ,,
24th ,,	- - - - 1 ,,
28th ,,	- - - 1 ,,
10th November	- - - 1 ,,

These regiments were sent into camps without any disinfection of clothing or kit, as they were moved into tents.

21,253. Had there been any disinfection among any of these regiments?—No; they were marched out without disinfection of any kind. The following additional precautions were taken after moving these camps: each corps had a Banniah with it in camp who was required to purchase weekly the grain required for the men, and not to issue it until it had been exposed to the sun and air for 24 hours; the guards over the lines were on duty for a week, and during that time were not allowed to enter the Quarter Guard or any of the buildings, but were accommodated under canvas, and on being relieved were segregated for another week before being allowed to rejoin their regiments; as cases still continued to occur it was thought that this was due to the families visiting the bazar, and therefore the next precaution was to move the families away from the men and further from the bazar, and also to place guards over them, to prevent them leaving their camp. No further cases occurred amongst these Native Infantry regiments after this last precaution.

21,254. I believe plague broke out in the Transport lines among the followers?—Yes. Plague broke out in the Transport lines among the followers and their families, about 400 strong, on 5th October, and up to 4th November 24 cases had occurred; on that date the whole of the followers and their families, numbering altogether about 400, were moved into camp near the rifle range, but as 14 more cases occurred, arrangements were made on 13th November to move the camp a few yards to the front across the main road running parallel thereto. Each tent was sprayed with perchloride of mercury solution, then carried across the road and put up; the followers and their families including even their cats and dogs, their cocks and hens were carefully disinfected before being allowed to cross the road and re-occupy their tents; the experiment was eminently successful, for after that date not a single case of plague occurred among those who had crossed the road, proving convincingly the efficacy of disinfection.

21,255. How did you disinfect the cocks and hens?—I think I may say that that is a joke of the late General Duncan. I believe it is a fact that they were dipped into the perchloride of mercury solution before crossing the road, but I am not sure that I directed that extreme measure.

21,256. Did you disinfect the clothing?—Every single article that these people possessed was dipped.

21,257. The result was that you had no plague?—The result was that there was not a single case of plague across the road, except two children I found ill in a family on the right hand side of the road. We left them there, and they developed into plague in a day or two. There was also one case of a man who was left on watch in the Transport lines. He was the only man left in the lines. A few days after this health camp had been carried out, this man died of plague in the lines. I think that shows that infection was still rife in that ground, and did not travel across the road with the people who had been disinfected.

21,258. Plague went on in the cantonment?—Yes.

21,259. What measures did you take in the cantonment?—On the 17th of November the Plague Committee, as established by the Government of Bombay, commenced actual work. On the 27th of November, a Plague Committee was formed by a Government order, but we commenced work on the 17th November. At that time there was a great deal of confusion. People on plague duty were overworked. According to our views, and according to General Duncan's opinion, all was not being done that could be done, chiefly owing to the men on plague duty being overworked. On the 17th of November, arrangements were made for a more efficient manner of dealing with it, or, at all events, a more complete method of dealing with it. Major Ross was placed in chief executive charge. Plague at that time was so diffused throughout the cantonment that it was exceeding difficult to grapple with it, and, after careful consideration, it was decided to completely surround the enemy, and attack him simultaneously from all quarters. With this in view, the cantonment was divided into three divisions, each under a British officer, and each division was divided into a number of sub-divisions, in all 17, each under a supervisor, who was either a Native gentleman or a pensioned Native officer. Each supervisor had to prepare a list of all the inhabitants in his sub-division, with the object of keeping a check on arrivals and departures, and by this means to facilitate the segregation of the persons arriving from infected areas. Each subdivision had a search party, varying in numbers according to the density of the population in the particular area they had to search. Each division had a depôt or head-quarters, where the divisional establishments were located during work hours, and the depôts were as follows:—

No. I. Division—Nusserwanjee Petit Hall, Bhawani Pet Road.

No. II. Division—Charitable Dispensary, Connaught Market.

Lieut.-Col. W. J. Fawcett, R.A.M.C.

23 Feb. 1899.

No. III. Division—Camp, Brigade Parade Ground.

The divisional establishment was common to all the sub-divisions of each division, and consisted of:—

Medical official.
Ambulance party.
Disinfecting party.
Whitewashing party.
Segregation party.
Four ambulance carts.
Two disinfecting carts.
Two limewashing carts.
Two coolies carrying basins and bottles of disinfecting lotion, for the use of the search parties to disinfect their hands and clothing at once after handling a case.

No. I. and II. Divisions each had two lady searchers for visiting Muhammadans' houses where there were pardah ladies, and each lady was accompanied by a small escort of two soldiers. With this sub-divisional and divisional establishment nearly every house in Cantonments was searched daily. As cases were found by the different search parties, intimation was sent to the depôt. The Medical Officer went to diagnose the case; if pronounced plague, ambulance, disinfecting and segregation parties followed. The patient was removed to hospital, with one member of the family as an attendant, the remainder of the family or household were taken to the depôt for segregation. The effects were removed from the house, either left with the neighbours, sent to a store kept for that purpose, or taken with the family at their own discretion, and the house was disinfected and closed. Whitewashing was carried out the following day. All persons collected for segregation during work hours were taken in batches at the completion of the searching of each Division to the segregation camp. Where dead bodies were found two soldiers were left in charge of the funeral rites. As far as possible, members of the household only were allowed to handle the body, the remainder being kept at a distance. The soldiers accompanied the party, and as soon as the body was disposed of, the members of the household were taken straight to the segregation camp by one soldier, and the remainder of the party who assisted at the funeral rites were taken to the nearest disinfecting depôt by the other soldier, they and their clothing were disinfected and they were released.

21,260. Did you find much difficulty with regard to corpse inspection?—None whatever.

21,261. Corpse inspection was done before the body was moved?—Yes.

21,262. Did you find much difficulty among Muhammadan women?—None whatever. I have never heard of a complaint of any kind. Had there been any complaints I should have been sure to hear of them; but, as a matter of fact, I never heard of a single complaint. There are not very many Muhammadans living in the cantonment, but there is one lane which is certainly full of them. In any case there was a lady doctor available to visit Muhammadan women, if necessary.

21,263. What have you to say with regard to hospitals?—From motives of economy, the General Plague Hospital, and all private hospitals, consisting of four, Parsee, Muhammadan, Hindu, and Marwari, were all common to Poona City, Suburban Municipality, and cantonment. With the exception of the Parsee Hospital, they were outside Cantonment limits, and were entirely managed by the City Plague Committee, the cantonment bearing a share of the General Plague Hospital expenses.

21,264. I believe you issue death certificates?—Yes. There was reason to believe that the existing practice of accepting death certificates from other than Commissioned Medical Officers led to the concealment of plague in some instances, consequently orders were issued by the Plague Committee that death certificates from all causes other than plague would only be accepted from a Commissioned Medical Officer, and arrangements were made for a Medical Officer to be available at fixed hours, morning and evening, to view all dead bodies and to grant the certificate free of charge.

21,265. Did you evacuate the houses in which there was a plague case?—Every house in which a plague case occurred was evacuated completely.

21,266. For how long?—For 10 days.

21,267. Were the people placed in health camps?—When a case occurred people were placed in the segregation camp; the whole inhabitants of the house.

21,268. Were they allowed to go back to their work?—No, they were confined to the camp.

21,269. Do you think you got all the people to go into the segregation camp?—I should not like to answer positively with regard to that. I know we took an immense amount of trouble to get them all. I think we got very nearly all the people in Poona cantonment; but then you must remember that we had an enormous staff, both of Natives and Europeans, and European soldiers and Native soldiers.

21,270. What percentage of people do you think escaped?—I could not give the numbers.

21,271. In your opinion, would it be 5 per cent., or 20 per cent., or what?—Nearer 5 than 20 per cent.

21,272. I believe the people were made to take a bath in a solution of carbolic acid, 1 in 40, on entering camp?—Yes.

21,273. Do you think the people found that very painful?—That was modified, and phenyle was used afterwards on some occasions. I do not think that a bath in a solution of 1 in 40, made up with soft soap, is painful. I have often had my hands in a solution of 1 in 20 for a considerable number of hours a day.

21,274. I should think that to the scrotum, for instance, it might be?—There was never any objection made. Hundreds passed through the tubs.

21,275. Did the people go voluntarily into the health camps?—Not quite voluntarily. Major Ross and myself decided, on one occasion, to evacuate a certain block, it being riddled with plague cases. We went down in the morning and said to the people, "Now you have to go out." We got carts for them, and any number of soldiers to help them. They went out very quietly and happily, especially after they had seen some blocks evacuated. Towards the end of the epidemic they had their things ready, and were out in two or three hours.

21,276. You never evacuated a whole town?—Not at the same time.

21,277. Could you tell us how many deaths you had in the segregation camp?—No.

21,278. Could you tell us the number of cases?—No; I do not think they have been recorded. I have tried to obtain the information.

21,279. Can you give us the number of deaths in the health camps?—No. I can absolutely state, however, the number of cases of plague.

21,280. There was only one?—One absolutely; nominally there were one or two others.

21,281. Did you have a roll-call in the health camps?—Yes, at nine o'clock at night.

21,282. Did you find that all the people turned up, or did a certain number of them escape?—A certain number of them escaped.

21,283. How many?—A small proportion. The people were punished; it was not worth while to be absent.

21,284. How do you know that people actually answered to their names; might not someone else have answered for them?—We had a Native officer and two corporals—sepoys,—and three or four men. The Jamadar called the roll. Each corporal had his division and each man had his sub-division. They soon knew the number of people in each hut.

21,285. I believe when the Wanauri bazar people were sent to the health camp, a small row of huts was overlooked?—Yes. When the bazar people were sent to the health camp a small row of huts was overlooked, and the inmates left undisturbed. Amongst these people five cases occurred and three terminated fatally within 24 hours. The remainder were then segregated without delay. This object lesson proved of great value, and was not forgotten by the people.

21,286. Were you able to turn out the people in Wanauri village?—We had not room in the health camp, and about 1,500 Wanauri villagers practically remained unattended to until January.

21,287. And plague went on?—Yes; plague went on and on in that village until the people themselves fled to their fields. They brought plague with them into the fields, and cases continued. Our search parties used to visit the huts in the fields, and all the cases which are shown as cantonment cases in January are

practically from the fields of Wanauri and Wanauri village.

21,288. I suppose there was no disinfection?—No. The people left their houses, flying into the fields. It was with considerable difficulty that we could find the cases. They were scattered over miles.

21,289. How did you disinfect the houses in the cantonment?—Every house in which a case occurred had the roof or a portion of it removed. First of all the interior of the house, the floors, the walls, and dusty corners were lightly sprayed with a solution of perchloride of mercury. Every moveable thing inside the house was removed. All the people's clothing which had been left behind (the people having gone to the segregation camp) was disinfected with perchloride of mercury solution. All the collections of rags and rubbish, and all odds and ends which were valueless (and which collect to an enormous extent in some of these native houses) were brought into the street and burnt. During the earlier part of the epidemic we took up the floors; but we very soon abandoned that as unnecessary. Then the whole of the interior of the house was sopped with perchloride of mercury solution, until the floor was a bog. This was all done under the supervision of a British soldier. Practically every house in the bazar was done under the supervision of a British officer. Every house was seen wet by a British officer. As soon as it had dried it was whitewashed. The latrines were most carefully attended to; in fact, not a detail that one could think of was left undone.

21,290. Did you demolish any house?—Yes, we demolished a considerable number of houses.

21,291. How many?—The details are given in Appendix "B" of my "Report on Plague in Poona" and Kirkee Cantonments and Suburban Limits, from "17th March 1897 to 19th March 1898."* They may be summarised as follows:—70 houses were demolished or pulled down to be rebuilt, and one house was improved by the provision of windows for ventilation. This cost Rs. 5537 in payments of compensation money.

21,292. Have you anything to say with regard to the manner in which insanitary houses are formed?—Yes. It may be of interest to describe the process by which these houses get into this insanitary state, a procedure that can be seen in full operation in any regimental or Sadr Bazar, but which has now received a severe check in this cantonment. The operations are as follows: A row of houses consisting of single or double rooms is sanctioned with a broad street between the rows. The inhabitants first proceed to make a small enclosure in front of their houses, marked by a row of stones; the stones are succeeded by a low mud wall; then a few sheets of tin forming a verandah are put up partly resting on the mud wall and partly on a few sticks; the wall rises in height and the sheets of tin increase in number from year to year; then a few tiles and rafters are put up and before many years go by there is a room or, if the owner is more enterprising than his neighbours, even rooms both front and back; though it is true the door-way is not more than 4 feet high and the inner rooms are quite dark, but these are not considered drawbacks by the inmates.

21,293. I believe you had some plague among European troops?—Yes. Two cases occurred in soldiers of the Royal Irish Rifles employed on plague duty in the city, one on the 20th and one on the 29th of January, both patients were in hospital at the time plague was diagnosed, suffering from venereal disease, admittedly contracted while on their rounds in the city. On the 4th November 1897 a woman, the wife of a sergeant living in the Wanauri Barracks, was attacked. She had recently been shopping in the Sadr Bazar. All three cases ran a very similar course ending in recovery after a prolonged convalescence. In the cases of the two men the bacillus was searched for and it was recognised in one. All three patients had buboes in the groin, which suppurated. One of these men had been inoculated in April; in fact, he had been inoculated twice with Haffkine's serum. He got plague in January. The other had not been inoculated. About 50 men had been inoculated and 1,900 men had not been inoculated. One of the 50 inoculated men got plague, and one of the 1,900 inoculated got plague.

21,294. (*Prof. Wright.*) How long after inoculation?—The inoculation was performed in April, and he got plague in January—10 months.

21,295. (*Dr. Ruffer.*) I believe a certain number of squirrels died of plague, did they not?—Yes. In December 1897, when plague was very bad, I noticed squirrels crawling along the road, and not able to go up the trees. Then I heard some people saying that they saw three squirrels drop off the trees dead. After that I could at any time find the corpse of a squirrel about here if I looked for one.

21,296. Have you any evidence to show that these squirrels died of plague?—No.

21,297. I believe a grey squirrel in a cage died in the house of a European woman?—The wife of a sergeant who was attacked in November had a pet grey squirrel in a cage in her room, and it died suddenly the second day of her illness, when she was going to the hospital.

21,298. You have no evidence to show that that squirrel died of plague?—None whatever. I was too busy at that time to make any experiments.

21,299. What measures did you take to prevent re-infection?—By the middle of December the epidemic in cantonments was considered checked, and the following measures were adopted to prevent re-infection:—

1. A corpse inspection by a Medical Officer in every case of death.
2. Every case of sickness in the native population to be at once reported by the head of the house to the Supervisor of the district, by whom it was at once brought to the notice of the Medical Officer on plague duty, who, with the least possible delay, saw the case and determined the nature of the complaint. Both these measures worked wonderfully well and smoothly, the people knew and trusted their medical man.
3. Every arrival from outside the station had to spend 10 days in the health camp before being permitted to take up his residence in the bazar; but this rule was modified to suit many emergencies.
4. The normal population of the Sadr Bazar is probably 25,000, but by the end of November there were not more than 12,000 people in it at the utmost. All unoccupied houses were securely closed and sealed under the orders of the Cantonment Magistrate. No house was re-occupied until it had been well cleaned in the fullest sense of the word, disinfected and limewashed.
5. Surprise night visits were made by the troops on plague duty under their officers, and it was remarkable how few breaches of the regulations numbered 2, 3, and 4 were brought to light, and when a few delinquents had been punished the necessity for the night visits ceased. The people had learnt to trust in the plague measures, and to a great extent co-operated in them.
6. Under the Poona City Plague Committee a strict surveillance of all arrivals by rail was arranged for, those coming to cantonments were sent to the health camp, and if they came from an infected locality obliged to sleep there for 10 nights. Many modifications and relaxations of this rule were from time to time introduced but detailed description does not come within the scope of the present statement.
7. On the 16th January a sanitary cordon of cavalry was established around the city, cantonments, and suburban limits to deflect the traffic on to the main roads, where observation posts were established, supplied with disinfectants, and small camps were erected in which the people wishing to enter were detained till they were seen by a Medical Officer.

It may be noted that, as far as can be gathered, but six cases of sickness were sent during the whole time from the posts to the Plague Hospital.

21,300. Will you give us the orders for the cordon?—They were as follows:—

1. From 6.30 a.m. till 6.30 p.m. no carts, pack animals, or coolies carrying other than articles of merchandise will be allowed to pass through the cordon *except* by one of the authorised roads where there is a post.
2. Agricultural labourers, coolies carrying articles of produce for sale, persons in charge of cattle, and all persons without other effects than what they are actually wearing will be allowed to pass at all points.
3. The object of the cordon is to insure that all persons and families who have been living outside Poona will, with their effects, be properly

* Not reprinted with the Proceedings of the Commission.

Lieut.-Col. W. J. Fawcett, R.A.M.C.

23 Feb. 1899.

disinfected before being allowed to return to reside in their houses in Poona. The question of their disinfection and retention at the several posts does not concern the cordon, it will lie with those in charge of the posts, and the men employed on cordon duty are simply to insure that all such persons and families pass by the posts and not by other roads.

4. From 6.30 p.m. till 6.30 a.m. all carts, pack animals, or coolies carrying articles such as household goods and wearing apparel will be stopped outside the cordon and not allowed to pass. But all empty carts, unladen animals, night-soil carts, rubbish carts, and carts or animals carrying grain, produce, and articles of merchandise only, will be allowed to pass freely.

21,301. What were the orders for posts?—They were as follows:—

1. A cordon has been placed round Poona for the purpose of stopping the importation of plague by persons returning to reside there from infected areas.
2. Posts have been established at all the main approaches to Poona, and the duties of the cordon are simply to make all such persons pass by the Posts and not by other roads, and to stop their passing at all during the night when the work at the Posts must of necessity cease.
3. The N.C.O. in charge of each Post will arrange for the inspection of all traffic that passes and will work as follows:—

(I.) All carts, animals, or persons carrying only articles of merchandise will be allowed to pass without detention.

(II.) All empty carts, night-soil and rubbish carts, unladen animals, and persons carrying nothing but their wearing apparel, will be allowed to pass without detention.

(III.) All carts, animals, and persons conveying articles of household use, bedding, clothing, &c., will be stopped either passing in or out.

(*a.*) All those passing out will have their persons and effects disinfected, and they will be allowed to proceed.

(*b.*) Those passing in will be disinfected and detained till an Officer on plague duty decides what is to become of them.

(IV.) Europeans in Government employ will, with their servants and belongings, be allowed to pass at all times.

(V.) All persons showing signs of sickness will be sent or detained for medical inspection.

(VI.) Persons arriving at a Cantonment Post, who propose to reside in the city, will not be disinfected in cantonments, but will be passed under escort to the City Segregation Camp, Parvatti Road, with a note of their numbers. Persons arriving at a City Post, who propose to reside in cantonments or Suburban Municipality, will be similarly passed under escort to Cantonment Health Camp, Shunkerset Road.

21,302. What are the Sanitary Orders for Troops on Plague Duty?—They were as follows:—

1. They are to live in camp.
2. Sober men only are to be chosen.
3. The working parties are to be inspected by a Medical Officer daily before they move off; those with any sign of fever or debility to be struck off duty.
4. Abrasions on the hands or face are to be specially looked for; the men may grow beards.
5. A good breakfast is to be supplied before work begins.
6. Arrangements should be made to supply a midday meal in cases where the men cannot return to camp in time for their dinner.
7. Putties should be worn to prevent the dust from infected houses coming in contact with the legs.
8. It should be impressed on the men that a fruitful mode of infection is through abrasions on the skin, and all such should be reported at once to the Medical Officer.
9. A supply of carbolic lotion, 1 in 40, is to be sent with each party, and in the interval of work the hands should be swilled with it.
10. The parties should be warned not to commence thorough cleaning until some preliminary disinfection of an infected house has been carried out.
11. Disinfectants should be freely used in camps.
12. Immediately on return to camp from plague duty the whole of each man's clothes will be changed, and the suit taken off and hung in the sun, then each man will take a bath with phenyle in it; carbolic soap will be liberally supplied.

21,303. I believe there was also some plague in the suburban part of the town?—Yes. That was in a tongue of land between the city and Poona cantonment and Kirki. It also contains the Poona railway station. For a long time every case found in the railway station was shown as an imported case of plague in the Suburban Municipality.

21,304. Did you take the same measures?—Practically the same measures.

21,305. In your report* on plague in Poona and Kirki cantonments and suburban limits, you give some medical notes on the late epidemic, and you say, "The "perchloride of mercury used must be the English "salt. A native-made salt, supposed to be perchloride, "has, I know, been used, but it is worse than useless, "as it consists of more than 50 per cent. of calomel, "as well as some sulphate of mercury, and clay." Have you had this native salt analysed?—Treacher and Co. told me that they had analysed it, and had found that it consisted chiefly of calomel, and something which they believed to be sulphate of mercury and clay.

21,306. In your experience has English salt been used, as a rule, or native salt?—When I came here native salt was the only thing used.

21,307. Native salt is very much cheaper, is it not?—Yes. It was impossible to make the solution with it. It was issued in packets, and each packet is supposed to be sufficient to form a bucketful of solution of 1 in 1,000. I examined some of the packets. The weight, I think, should have been 184 grains; but the weight of these packets varied from rather less than $\frac{1}{2}x$ to $2x$. It was impossible to make more than from 30 to 50 per cent. of any single packet dissolve in water.

21,308. Can you tell us how much clay the perchloride of mercury contains?—I do not know. There were impurities.

21,309. There must have been a considerable quantity of impurity if only 50 per cent. dissolved?—You could not make 50 per cent. of native salt dissolve with any amount of sodium chloride.

21,310. So that your 1 in 1,000 only contained ·2 per cent.?—It is something very small. Even by the addition of acid you could not make more than 50 per cent. of the native salt dissolve.

21,311. Do you think that the native habit of sleeping on the floor has anything to do with their getting plague?—I think so. It is, however, merely a matter of opinion, and not of fact.

21,312. (*Mr. Hewett.*) The habit of sleeping on the floor is more prevalent in this part of India, than in Northern India, is it not?—Yes. Charpoys are very generally used in the north of India, and I think that may have an influence in causing a plague epidemic to be more easily controlled in Northern India than in Southern India.

21,313. In your Report* you say that the total number of cases in Kirki was 690. What was the population among which these cases occurred?—3,700.

21,314. In Poona cantonment there were 422 cases among a population of 12,000?—At that time the population had probably sunk to 12,000.

21,315. The number of deaths at Kirki was 561?—Yes.

21,316. And in Poona cantonment 298?—Yes.

21,317. Was there anything particular in the character of the population of these places which made your task easier than it might have been in other parts?—I think so. The people were well acquainted with the habits of Europeans. They were people whose livelihood depended upon the Europeans living in Poona. They were not afraid of Europeans; they had been accustomed to them all their lives. This, undoubtedly, made our task much easier.

* *See above.* Not reprinted with the Proceedings of the Commission.

Lieut.-Col. W. J. Fawcett, R.A.M.C.

23 Feb. 1899.

21,318. Do you consider that even passive opposition on the part of the people would have made your task much harder?—No one could hope to control an epidemic unless the population were on his side.

21,319. (*Prof. Wright.*) Did you find any objection to disinfection, did the people try and conceal their best clothes or bribe the disinfectors?—I think it is hardly possible. I have known a bribe offered to British soldiers, but it was quite useless. The people had much better submit; and they did submit. I do not think there was any concealment. At the first the lady of the house would do her utmost to conceal her best belongings, and carry them away through the back door, as soon as she knew a search party was coming. Very little could be done with success, however, in that direction. We had such an enormous body of people helping us that the back door was as carefully guarded as the front door. There was no escape.

21,320. (*The President.*) Do you endorse the opinion of Major Ross, which you have quoted in your Report* ?—Yes. Major Ross writes:—"The effect of health-"camping was almost magical: of 4,000 people taken "from the worst infected areas, only one undoubted "plague case occurred after they had returned to "their houses: in that instance the woman who was "attacked was only six days in camp, and was taken "ill the evening of the day she left." I believe that firmly; in fact, I can go further and say that the total numbers were 6,100, and that was the only undoubted plague case that occurred after the return of those 6,100 people from the health camps.

21,321. You endorse it from your own observation?—Entirely.

21,322. What do you mean when you state, in your Report,* "On the other hand, no disease is so easily "combatted by the resources of the modern sanitary "science"?—In my experience, the measures which were successful in removing plague from Poona cantonment were those which, if applied to an epidemic of scarlet fever or diphtheria at home, would not produce the same results. Plague, in my idea, is a purely local, narrow disease, and is easily dealt with. Its means of spreading are so local and few that it is perfectly possible, by following out the ordinary sanitary rules, which would be applied in every epidemic, to obtain a much more successful result than when dealing with an epidemic of any other infectious disease. Nothing but these facts would justify the amount of money we have spent on plague; a similar expense in an epidemic like scarlet fever in England, or here, would be waste of money, because the results would not be commensurate. I hold that the results have justified the expenditure. I may also say that I have heard it said that the measures were taken on a falling epidemic, and were therefore successful. But I must say that these measures in our instance, neither in Poona cantonment, nor in Poona city, were adopted on a falling epidemic. The epidemic increased, or certainly held its own for the first weeks afterwards. It rose for two or three weeks before we commenced our measures. We commenced our measures in Poona cantonment on the 17th of November, but it was not until the beginning of December that efficient measures were adopted in Poona city; yet the epidemic continued as virulent in Poona city as it had been, while it was declining in Poona cantonment.

21,323. Do you still adhere to the opinion you have expressed in your précis that "It is unfortunately an "axiom that plague in its epidemic form is only to be "found where dirt, darkness, and overcrowding pre-"vail; in a word, in those places where sanitation is "unknown, impossible, or neglected. Most fortu-"nately, it cannot be carried to any appreciable "extent by water or air, and the bacillus which causes "it, though capable of multiplication with extra-"ordinary rapidity in a suitable nidus, has neither "power of resistance, locomotion, or spore formation, "and dies at once in the light of day"? Does that entirely represent your present views?—Yes; I hold by every word of that.

21,324. On the last page of your précis you express certain views with regard to inoculation. I suppose those views are based partly on your own observation?—Yes. Observation and reflection, I think, enable me to draw the conclusion that it would need to be universal in order to be successful.

21,325. Will you read what you say?—That is what I say:—"I feel that I have not sufficient experience "to add anything to the knowledge of inoculation and "its uses; but I may be permitted to say that it "appears quite clear that if inoculation is generally "adopted, in supersession of the ordinary sanitary "regulations, as a measure for the suppression of "plague, it should be universal, which is obviously "impossible; because, if any minority in an infected "city remains uninoculated their doom is sealed, they "must be practically exterminated. A little reflection "will prove this, while the inoculated are, in a great "measure, protected for a limited time, and are "thereby given a feeling of security, their houses, "clothing, bedding, etc., continue to hold and carry "the seeds of the disease, and will undoubtedly dis-"seminate it far and wide, to the utter destruction of "the uninoculated minority."

21,326. From as full a consideration of the subject as you have been able to give, you still endorse those opinions?—Those are the conclusions I have arrived at. It is true that they are not absolutely mathematically correct, but they are conclusions one arrives at from experience and reflection upon the subject.

21,327. (*Dr. Ruffer.*) You say in your précis, "The "sanitary cordon as adopted round the city and can-"tonment in January 1898 appeared necessary at the "time, but it can now be shown that it was not really "required." Kindly tell us upon what you base that statement?—I am afraid it would be very difficult to show that absolutely. I am prepared now to think that it was not really required at the time.

21,328. Why?—Because, after we had put it on, we came to examine carefully into the working of the cordon, and we found, especially at night, that it was perfectly easy to get through. Internal quarantine, as I said at the time it was put on, can never be effective. Anyone who chose to get through it, especially at night, could do so with greatest facility. One could take a horse, or a carriage and four, through it if one wished. There is not the least difficulty.

* *See above*; not reprinted with the Proceedings of the Commission.

(Witness withdrew.)

Mr. H. C. Venis.

Mr. H. C. Venis called and examined.

21,329. (*The President.*) You have had experience of plague duty in Poona?—Yes.

21,330. Have you an official position here?—I was sent out by the Secretary of State for India.

21,331. Will you mention your medical qualifications?—L.R.C.P., L.R.C.S. Edin.

21,332. (*Prof. Wright.*) What duties do you perform at present in Poona?—My duties include a variety of things—my chief duties are corpse inspection and examination of the sick.

21,333. Is every case of sickness notified to you?—Yes. Cases of illness in the city are reported by the friends of the patient, or by the volunteers either to the Medical Officer on duty at the Central Plague Office, or to the Cheif Volunteer at the Ward Office of the division in which the patient lives. The Chief Volunteer then forwards the report of the sick to the Medical Officer.

21,334. Do you look after one ward or one division of the town?—No, we (*i.e.*, my colleague and I) are the Medical Officers of the whole city.

21,335. Do these notifications of sickness come in?—Yes, either by the friends of the patients directly to the Medical Officer at the Central Office, or through the agency of the volunteers.

21,336. Do the Medical Officers attend all through the 24 hours?—They attend for 12 hours from seven in the morning till seven in the evening.

21,337. No Medical Officer attends during the night?—No.

Mr. H. C. Venis.

23 Feb. 1899.

21,338. Notifications of the sick all come in during the day?—Yes.

21,339. When they come in do you go immediately to see the sick person?—Yes, but if there are some corpses to be examined, the sick are taken after the examination of the corpses, or on the way there; it all depends upon circumstances.

21,340. Is there opposition to your examining the sick?—During my 15 months' experience I have had only about two or three cases in which the friends of the sick person objected to medical examination.

21,341. Is every case of sickness reported to you, such as a case of diarrhœa?—Yes, all cases of sickness.

21,342. Even mild attacks of fever?—Yes.

21,343. And headaches? I want to know whether the cases of sickness which are reported are only grave cases?—No, not only the grave cases. I had a case of deafness reported to me yesterday morning.

21,344. There are comparatively slight cases among these returns?—Yes.

21,345. Then you go round and see them?—Yes.

21,346. What examinations do you make of them? Do you content yourself with determining whether they have plague, or do you examine them to see what is the matter?—Up to last February, when plague was rife, we did not diagnose beyond seeing whether a case was plague or not, but after that time, when the epidemic died away, we arrived at an approximate diagnosis in each case.

21,347. And that is your practice at present?—Yes.

21,348. Did you find many of these patients had been sick for a number of days before you were called in?—Some of them.

21,349. What are the regulations—that they shall report one day's illness to you?—No. Parties of volunteers go round in each division of the district. They notice the sick people in their homes and report.

21,350. Do the volunteers go into the houses?—Yes, native gentlemen, who have volunteered to report cases of illness.

21,351. What is their work? Do they go into houses and force an entrance, or are they allowed to go in voluntarily?—They are allowed to go in voluntarily. They ask at the doors if anyone is sick.

21,352. Does most of the information come to you by means of the volunteers, or is it notified by the relatives?—About half and half. The people voluntarily report cases of sickness now.

21,353. When these deaths are notified to you, do you find that a large percentage of them had been notified to you previously as sick cases?—Yes.

21,354. What is the percentage?—From the 25th January to the 31st December 1898 I examined 1,809 sick people, and of those 601 died.

21,355. Every corpse had been previously seen by you during life?—Yes, *i.e.*, every corpse included in the number (601) mentioned above, which is the number of those people who, previous to death, had been examined and certified by the Medical Officers. This is the form of certificate:—

No.

MEDICAL CERTIFICATE.

Name _____

Age _____

House No. _____ Peth.

Certified that I have examined this person and that _____ is not suffering from Plague but from _____

Special Plague Medical Officer,
Hd. Qrs. Segregation Office,
315, Shukrawar Peth.

Date ____ 189

No.

MEDICAL CERTIFICATE.

Name _____

Age _____

House No. _____ Peth.

Certified that I have examined this person and that _____ is not suffering from Plague but from _____

Special Plague Medical Officer,
Hd. Qrs. Segregation Office,
315, Shukrawar Peth.

Date _____ 189

The left-hand side is kept by us, and the right-hand half is given to the patient.

21,356. When you examine corpses do you issue another form of certificate?—Yes, I should rather call it a pass, a cremation or burial pass.

21,357. What examination of the corpses do you make to determine whether the person has had plague or not? Have you got that certificate with you when you go to see the corpse?—In many cases.

21,358. You examine the certificate which the patient had during life?—Yes, because we find it (*i.e.*, the left-hand duplicate of it) in the Medical Officer's Office.

21,359. If that says that the patient died of plague or was ill of plague you take no further steps?—That is so.

21,360. You make a fresh examination?—Yes, many of those certificates have been issued six or seven months before.

21,361. The patient had been sick six or seven months?—Yes.

21,362. Then you make a fresh examination of the corpse; what do you examine for?—Specially for buboes and glandular swellings of any sort.

21,363. Are there any other signs of plague which you can detect in a corpse?—The general appearance and the previous clinical history.

21,364. What is there in the general appearance which would put you on the track?—The last few cases which we have had in Poona City have been of the septicæmic type of plague.

21,365. How do you determine those to be cases of plague?—There is a peculiar facial expression about the corpse; the features are contracted, and there is a sort of anxious expression which the deceased had before death, and the eyes are fixed and glistening. The whole countenance has a worn expression, as it were; the cheeks are sunk in, and the tongue, in the majority of cases, exhibits a thick white fur, and in a few of the septicæmic cases, a black fur. By the time the Medical Officers arrive, if many hours have not elapsed, the body is distinctly warm. There are no buboes in those cases.

21,366. Do you find a plague corpse keeps warm longer than that of a person who has not died of plague?—Yes, it is a continuation of the increased temperature.

21,367. How soon after death is the corpse examined?—In some cases within half-an-hour or an hour, but if I am out on my rounds and the death is reported, it may be two hours before the corpse is examined.

21,368. A patient who dies after seven in the evening is not examined till the next morning?—That is so.

21,369. Is there trouble with the relatives?—We have had two or three complaints.

21,370. What are the complaints, that the laying out of the patient has been delayed?—Yes.

21,371. Have you any other complaints but that?—None that have been brought to my notice.

21,372. Do they object to your examining the bodies of females?—Not of females particularly. I have had two cases of objection which I have called case A and case B in my précis of evidence.

21,373. Perhaps you will tell us what the objections were founded on?—The first case was that of an ascetic, a holy man, a Fakir, I had seen this patient myself, and he was suffering from dysentery. He had also been under treatment at the Sassoon General Hospital, from which institution he got the certificate. When I saw his corpse about five days after my first visit, I had no need to examine the corpse because I myself had seen. His friends produced a certificate which I had given him (the right hand duplicate), and they also produced a certificate from the Surgeon of the hospital. There was no swelling, and the cause of death was quite plain. In another case an objection was raised on the ground of the patient's caste. He was a Brahman, and they asked through the Chief Plague Authority if a Brahman medical man might examine the corpse for buboes in the presence of a Medical Officer. This condition was readily granted, and the native medical man examined the body in my presence. I was as close as possible, and satisfied myself there were no buboes.

21,374. Those are the only cases?—Those are the only two cases in my experience lasting 15 months.

21,375. You have examined all the female corpses just the same?—Yes. My colleague, Dr. Botenson, had an objection raised when he was examining a female corpse, but that has not occurred in my experience.

21,376. How many cases of plague have you detected by corpse inspection?—106 cases of plague out of a total of 3,035 corpses examined.

21,377. How many of those cases were detected as plague cases during the corpse inspection which had been recognised to be plague when they were previously visited?—I cannot answer that question because when a case is diagnosed as plague it is sent off to the Plague Hospital or the observation ward, and they die there.

21,378. These are all cases which were not recognised as plague in the sick visitation?—Yes.

21,379. You think the visitation of the sick by itself would not suffice, because these 106 people slipped through your hands during the sick visitation?—Yes. (Witness, in correcting proof of his evidence, added a note correcting his statement as follows:—None of these 106 cases of plague were seen during life, and they were seen for the first time as corpses.)

21,380. How many plague cases did you discover when you visited the sick?—The total number of cases of illness in Poona City examined during life and certified by the Special Plague Medical Officers from the 25th January 1898, to the 31st of December 1898 was 1,891, and of these cases 601 resulted fatally. From March up to about the end of December, by means of our sick examination system, we discovered 25 or 26 cases of plague which were sent to the Plague Hospital or to the observation ward. Before that I had no figures.

21,381. Out of every five cases of plague discovered by means of sick visitation and corpse inspection, was only one discovered by sick visitation and four by corpse inspection?—Yes.

21,382. You think that of these two measures corpse inspection is by far the most useful?—It is very valuable.

21,383. Do you think the sick visitation might be omitted?—No, I do not think so, because that is a very useful mode of procedure too in helping us to detect cases of plague in the early stages.

21,384. What advantage do you think you get from that:—the lessening of the spread of inspection?—Yes, certainly, because as soon as a case is seen and diagnosed to be plague, arrangements are made for the removal or treatment of the patient, and thereby the further spread of the disease is prevented.

21,385. In your whole year's work you only found out 25 cases by your sick visitation?—Yes; they were seen and removed within a very short time.

21,386. Were these cases which you took out moribund or in the early stages of plague?—In the early stages, many of them.

21,387. If they had been moribund, I presume you would have got them a few hours afterwards as corpses?—Yes.

21,388. Do you know how long they had been sick, or were the facts you got not sufficiently trustworthy?—We have notes of all these cases which will be produced by the Chief Plague Authority.

21,389. Have you any other duties in connexion with plague besides sick visitation and corpse inspection?—Yes; I had medical charge of three camps—the railway detention camp, the segregation camp, and the Bhamburda health camp.

21,390. Are there any statistics available to tell us what the percentage of attacks was in the segregation camp?—Yes, I will supply those.

21,391. Can you compare those with the incidence of plague in the town? Can you tell us whether the percentage of attacks among the contacts was greater than the percentage of attacks in the town?—Yes. (The following statement was supplied later by the witness:—

Week ending.	Segregation Camp.			City.	
	Cases.	Admissions.	Percentage.	Cases.	Percentage.
8th October -	3	420	·710	114	·190
15th „ -	3	169	1·775	180	·300
22nd „ -	3	218	1·376	242	·403
29th „ -	6	324	1·851	347	·578
5th November	6	556	1·079	396	·660
12th „ -	5	986	·507	316	·526
19th „ -	3	850	·352	413	·688
26th „ -	9	971	·926	382	·636
3rd December	4	527	·759	376	·626
10th „ -	3	502	·597	424	·740
17th „ -	2	539	·371	334	·556
24th „ -	2	717	·278	211	·351
31st „ -	2	391	·511	155	·259

The percentages of attacks are taken week by week, from 2nd of October to the 31st December 1897, this being the period during which the epidemic was at its height. The comparison with the percentage in the City is not easy to obtain owing to the great exodus of people during the epidemic, and is taken for the same three months for 60,000 people. The total percentage is given below, the mean between the epidemic population and the normal being taken as a fair average of the population during the whole outbreak. The percentage for the City for the whole epidemic, taking the population at 90,000, is 5·16.)

21,392. Have you done any disinfection work?—Lately I have been placed in charge of disinfection work.

21,393. What houses have you disinfected?—The Medical Officer, in the course of his rounds, makes a note of all the houses in which plague deaths have occurred, or plague sicknesses, and he reports those to the Central Office. There are two Superintendents for the city of Poona, and they take out disinfecting parties to disinfect those houses.

21,394. Who are those Superintendents?—Captain Lockhart Muro and Mr. Holland.

21,395. Are these officers directly in charge of the disinfecting parties?—Yes.

21,396. How many disinfecting parties go out in the day? Are there only two disinfecting gangs, each with with an officer?—There are so many men available at the present time for this disinfecting work, and those men are divided up. If the houses all happen to be in one direction in the division of one officer, he takes the whole party.

21,397. Is there a European officer sent out with every gang?—A Superintendent goes out with a party.

21,398. Does a European officer superintend the disinfection of every house?—Yes; the European officer being the Superintendent as well.

Mr. H. C. Venis.
23 Feb. 1899.

21,399. Where are the disinfectants made up?—At the Municipal Technical School, where the disinfecting apparatus and materials are stored. The disinfectant used is an acid solution of perchloride of mercury.

21,400. Are those concentrated disinfectants?—Yes.

21,401. Do you know what strength they are?—1 in 725, that is what we are using at the present time.

21,402. That is not the solution sent out?—No; it is sent out in a strength of 1 in 100.

21,403. A 1 per cent. solution is sent out, and that is diluted?—Yes. A wooden corn measure is taken filled with the original solution; that is placed in a wooden bucket, and water is added from a pail to about four inches from the top. That makes a solution of 1 in 725. For the disinfection of clothes we use a strength of 1 in 1,000.

21,404. You dilute the solution 7·2 times?—Yes.

21,405. Why was this inconvenient measure taken?—It is convenient for us, because it is very easily obtained. Each disinfecting party takes the solution with them in small casks. We can easily get water in Poona, and the solution is made to this strength on the spot.

21,406. How is the disinfectant applied? Is it sprayed on?—We have pumps. Before the coolies are allowed to enter a room the floor is wetted with the solution. To protect the coolies, I may add, I was supplied with wooden sandals to protect their feet. Then the floor is scraped up, and the floor and walls are thoroughly disinfected.

21,407. Has everything been removed from the room before disinfection was undertaken?—Yes.

21,408. How are the articles which are removed disinfected?—With the solution.

21,409. Are they dipped into the solution?—Yes, at the discretion of the officer in charge of the party.

21,410. How is this discretion exercised?—The clothes are disinfected in the solution of 1 in 1,000.

21,411. Supposing they are clothes which would spoil with the solution, what is done? Is there an alternative measure?—We have compensation, and so on.

21,412. What is done with the metal vessels?—They would not be disinfected.

21,413. Are there a good number of articles which may escape disinfection?—Certainly.

21,414. Do you know whether any cases of plague have occurred in your disinfecting gangs?—No cases have been brought under my observation since I have been in charge.

21,415. Have disinfecting gangs been inoculated with Professor Haffkine's prophylactic?—No.

21,416. You have sent in a statement showing the statistics of corpse inspection, with a variety of diagnoses; do you put that statement in?—Yes. It gives the total number of corpses examined, together with the probable or approximate cause of death in each case. No *post-mortem* examinations are made, therefore the exact cause of death is not ascertainable. The statement is as follows:—

STATISTICS of CORPSE INSPECTION, POONA CITY, 1st January to 31st December 1898.

Probable Cause of Death.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total Deaths from each probable Disease.

21,417. Are these diagnoses arrived at by corpse inspection?—Yes.

21,418. You have diagnoses, for instance, of snake bite and spleen; were those diagnoses made at the corpse inspection?—Yes, from the clinical history and from the mark of the snakebite, and so on.

21,419. Would you be able to make any of these diagnoses independently of the medical history which has come to you?—In many cases we can; we could see for ourselves.

21,420. Let us take these things one by one; could you see alcohol?—We had the history of the three cases of alcoholism mentioned in the table. They were examined and certified during life.

21,421. I am asking you, could you diagnose it independently of the history, because the history depends on the patient who may give you a wrong history?—We go by the history and the general aspect.

21,422. You do not profess that these diagnoses, such as alcohol, blood diseases, and bronchitis, are all derived from corpse inspection?—No, they are the approximate causes of death, arrived at by a general consideration of the facts of the case. All these diagnoses are found by corpse inspection *plus* previous examination of the deceased during life, because many of them were certified. The clinical history was gone into as fully as possible, and the approximate cause of death arrived at.

21,423. (*Mr. Cumine.*) What is the population of that part of the town in which you had the inspection of sick persons and corpses?—Not less than 130,000. We inspect the whole city.

21,424. Do you, personally?—I and my colleague personally..

21,425. What is the penalty for not reporting sickness?—There is no penalty—at the present time, that is to say.

21,426. What is the penalty for not reporting a death?—There is no penalty now.

21,427. Supposing a person is found to be dead at 7 in the morning, what means have you of knowing whether he was ill before 7 o'clock the previous evening? When plague is very virulent people are taken ill and die within 12 hours, do not they?—Yes.

21,428. When they are reported to be dead at 7 o'clock in the morning, what is the means that you have for knowing that they were or were not ill before 7 o'clock the previous evening?—The clinical history supplied by relatives and friends of the deceased.

21,429. Supposing they declared the man was not ill before death, or that he was taken ill after 7 o'clock in the evening, what means have you of knowing it is not true?—We have no direct means, but we reconcile the statement with the general appearance of the body.

21,430. What is the largest number of corpses you have ever had to inspect of people who have died during the 12 hours of night?—I have examined as many as 27 corpses in one day, and 18 in the morning, but I cannot tell you how many died in the previous 12 hours. Some of them I know died an hour before I arrived.

21,431. 18 is the largest number you have had to examine in one morning?—Yes.

21,432. How long would it take you to examine 18 corpses?—These were not reported at the same time. They were in different parts of the city, and reports came to me up to 11·30 or 12 in the day.

21,433. So that the inspection of these corpses took you to 11.30 or 12 in the day?—Quite that.

21,434. If somebody died at 5 minutes past 7 on Friday evening, his corpse might not be examined until 12 o'clock mid-day on Saturday?—That is not so, because that particular case would be reported the first thing in the morning by the friends of the deceased and that corpse would be seen first.

21,435. What is the maximum number of deaths which you have had reported to you at 7 o'clock in the morning as having occurred within the previous 12 hours?—I cannot tell you that. I do not think we have a means of knowing, because we do not keep the hours at which reports are made by the friends.

21,436. How long does it generally take you to get through the corpses of people who have died in the preceding 12 hours at night?—On the occasion I have mentioned, when I had 18 corpses, they were finished at about a quarter to 12.

21,437. It is possible, is it not, that a person might die at 7 o'clock in one evening and the corpse not be examined till 12 o'clock the next day?—If the cases were reported at 9 or 10 o'clock I would be on my rounds which would fully occupy 1½ hours, because the sick have to be examined, especially urgent cases of illness. When I come back, if there are four or five deaths reported, I start out again.

21,438. What is your answer then?—I say it is impossible to tell, because we do not notify the time at which death reports are received at the Medical Officer's office, but I should not think it is possible, because if a person died at 7 o'clock at night the friends would be anxious to give information the first thing in the morning, and then that corpse would be seen forthwith.

21,439. When you go to breakfast in the middle of the day, who is there present to do corpse inspection of any one who may die?—There is an interval of three hours.

21,440. Then you are not on duty ready to do corpse inspection from 7 in the morning till 7 in the evening?—The work is divided between the two Medical Officers from 7 a.m. to 7 p.m., with the exception of an interval at noon.

21,441. What is the interval in the middle of the day during which there is nobody on duty?—From 12 to 3.

21,442. Supposing that by 12 o'clock you had not finished an inspection of all the corpses of people who had died at night and in the morning, what would you do?—We would finish them.

21,443. Is it not the case that sometimes in bubonic plague the buboes subside before the man dies, or just after?—I have not met with an example.

21,444. In some cases, I think, the disease was not diagnosed as plague in the lifetime of the person, but was diagnosed as plague after death. In how many cases did that occur? Was it 106?—These 106 were cases diagnosed which had not been previously reported—they were the corpses seen.

21,445. They had not been seen in life at all?—That is so.

21,446. Were these people living in Poona or did they come from outside anywhere?—I take it they were residents of Poona.

21,447. How had they got the plague?—The month of January (when plague was very bad) was the second bad month. You will remember that in the last outbreak of plague for the week eneing 11th December there were 470 odd cases of plague. In January the cases were 90, in February 10, and in March two, and in April one. Then we had one imported case in June and one again in October, making a total of 106. Then, of the imported cases which occurred sporadically, there was one in August, one in October, and one discovered by the surveillance system. Of course, these 90 cases were not seen during life; we were at the height of the epidemic, which was of a virulent type.

21,448. Since July last has there been any case where the patient has been seen in life but the illness has not been diagnosed as plague, but has been diagnosed as plague after death on corpse inspection?—No, there has not been any such case, because they were diagnosed during life. They were found out during life through our system of reporting sickness.

21,449. (*Mr. Hewett.*) How many of the 106 cases of plague which were detected by corpse inspection were bubonic plague?—The great majority were during the months of January and February.

21,450. Were any of them cases of pneumonic plague?—Not at that time.

21,451. What proportion of the people who are sick do actually report their sickness and obtain certificates, in your opinion?—We could easily calculate that. The present population has largely increased, and is now about 130,000. It has increased from last June, when the city got very full indeed. Out of that number, 1,891 have been certified up to the end of the year.

21,452. Do you think that half of the people who are sick report themselves as sick?—I should not think as many as half.

21,453. Do you think anything like half do?—No.

21,454. I see that you certified 45 persons in the month of June, and examined 210 bodies in that month What proportion of the cases of sickness do you think

Mr. H. C. Venis.

23 Feb. 1899.

were reported then?—That would be about one-fifth or nearly one-sixth.

21,455. Why would it be nearly one-sixth? It would be about one-fifth, assuming that almost everybody who fell sick and was not reported to be sick died of his sickness, would it not?—Yes; but, as I said before, it is almost impossible to tell, unless one went into all the districts of the city and found out which districts were reporting most cases of sickness and in which districts most deaths occurred during the corresponding period.

21,456. If all the mild cases of sickness were reported to you, would not you expect to find the number of cases of sickness far in excess of the number of deaths?—Yes.

21,457. Then in the months of November and December, when you certified 192 and 153 sick respectively, and when you examined 327 and 332 bodies respectively, a good deal of the sickness could not have been reported to you?—Yes.

21,458. Have the people here any objection to treatment by means of European medicines?—No. I cannot say that they have any great objection.

21,459. Do they prefer to be treated by their own medical attendants?—Yes.

21,460. Is the pardah system in force to any considerable extent here?—In certain parts of the city.

21,461. Among whom?—The Muhammadans.

21,462. (*Dr. Ruffer.*) Will you look at your statistics of corpse inspection of Poona city? (*See* Question No. 21,416.) In the month of January you had 90 cases of plague. I see that you had 63 cases unknown. Do you think some of them might have been plague?—These 63 cases were marked "Not plague" because no approximate cause of death was then required. This was during the height of the epidemic.

21,463. I do not understand why?—We either marked these cases as "plague" or "not plague." The diagnosis in these cases was that it was not plague. The approximate cause of death was not arrived at.

21,464. How do you know it was not plague?—The Medical Officer decided that.

21,465. How could you diagnose a case of plague pneumonia after death?—From the history and appearance of the body.

21,466. What appearance of the body or what history would enable you to diagnose a case of plague pneumonia from a case of ordinary pneumonia?—It would have the appearance of plague.

21,467. Supposing the man had no bubo?—In that case the clinical history would have to decide the point.

21,468. Suppose you had a case of acute pneumonia, how would that differ from a case of plague pneumonia?—It would not necessarily differ.

21,469. To what do you attribute the large number of cases of deaths from inanition in July, August, September, and October? I see the deaths from inanition jumped up from 24 to 59?—We include deaths from marasmus, lack of suckling, and deaths occurring among sickly and rickety children. At this time we had the rainy season, which is always a fatal time for weakly children.

21,470. To what do you attribute the great rise of death from bronchitis during September and October?—To extremes of temperature, cold chilly nights, followed by warm sunny days.

21,471. Does the Poona Municipality provide you with a microscope?—Yes, we have one at the Plague Hospital.

21,472. Have you the means of making a bacteriological diagnosis of a case of plague pneumonia?—No, but we are taking bacteriological specimens now, and we send them to Bombay for examination.

21,473. Have you an incubator and the necessary machinery for making cultivating media?—No.

21,474. Have you the necessary material for making cultivations?—Yes.

21,475. Then you can make a bacteriological diagnosis here in a doubtful case?—No; but we send to Professor Haffkine's laboratory.

21,476. Supposing you want to make a bacteriological diagnosis, would you make it here or would you send it to Bombay?—It would be sent to Bombay.

21,477. (*Mr. Cumine.*) Of these 3,035 people you have mentioned in your statistics of corpse inspection, was not the illness reported before death in any case?—That number includes all reported and not reported. This is a record of all the corpses seen from the 1st January to the 31st December, and includes cases reported during life.

21,478. With regard to these 106 deaths put down to plague, I understand you to say that you had received no previous notice of illness?—Yes. In this record we did not take into account the fact whether they were seen or not seen. This is only a statement of corpse inspection.

21,479. Do those 106 include cases in which the illness was reported before death?—No.

21,480. And cases in which the illness was not reported before death?—This only means *corpses seen in the city of Poona.* During the months of August and October two cases, which are marked "1" and "1" respectively, were seen by the Medical Officer, having been reported by volunteer gentlemen, and they were sent off to the General Plague Hospital, and died there. This does not include any which were seen by the Medical Officer and died in hospital.

21,481. Among those 106 corpses, were there some cases in which the illness had not been reported before death?—Yes, all of them, indeed, were cases "*not reported*" before death.

21,482. Are there some in which the illness had been reported before death?—None.

21,483. Can you tell us in how many cases the illness had been reported to you before death?—One case was seen by my brother (who was then my colleague) when *in extremis*, and death ensued in half-an-hour. Word was brought to him and he went back again. I think he had another case like that. These are all corpses actually seen after death. You cannot call them being reported in life, because the patient was in a moribund condition.

21,484. (*The President.*) Had you known of these 106 cases previous to the corpse inspection?—No.

21,485. I understand you to say that when you had information of a plague case in life you did not again examine the corpse after the patient died, but gave a pass for burial?—No, we saw the corpse.

21,486. Do you look at the corpse of every man who dies here?—Yes.

21,487. (*Prof. Wright.*) I understand that every case which is diagnosed as plague during life is sent to the Plague Hospital?—Yes.

21,488. Then his corpse is not re-inspected there, is it?—I do not know. We have nothing to do with the Plague Hospital's internal administration.

21,489. This does not include people who died at the Plague Hospital?—No; but yesterday morning a case was sent by my colleague suffering from plague, and the same day word was brought to me that that man had died from plague before removal to hospital, and that corpse was seen by me in the city of Poona.

(Witness withdrew.)

Prof. G. K. Gokhale.

Professor G. K. GOKHALE called and examined.

21,490. (*The President.*) You hold an office in the Fergusson College, Poona?—Yes.

21,491. What is your position?—I am Professor of History and Political Economy.

21,492. (*Mr. Hewett.*) You have only been employed during the second epidemic in Poona, I think?—Yes; I was doing work here as a plague volunteer during the time.

21,493. Between what dates?—From the middle of September to about the end of February.

21,494. What were your duties?—Up to the middle of November I had merely to accompany search parties

composed of soldiers, both British and Native. Afterwards, in addition to this duty of search I had to visit the detention and segregation camps on certain days, and advise the Superintendents of those camps upon matters on which they wanted to consult me.

21,495. Were you enabled to trace the source of the second infection at Poona?—No. The general impression here was that the poison was first imported from Kirki, but I am not sure that it was so, seeing that after the first epidemic we had stray cases occurring, say, one or two a week, in the town all through the intermediate months.

21,496. Have you any opportunity of discovering how a place gets infected with plague?—Yes. In my search work I often came across instances which appeared to me to indicate that the soil must be getting infected first, and that the infection must be spread chiefly through the soil.

21,497. What led you to form that opinion?—I found, for instance, that men who were sleeping on the ground floor were most liable to be attacked, while men who were sleeping on the first or second floor had very few cases among them. I also found that in the hospitals and segregation camps, where good care was taken to disinfect the soil, there were very few cases.

21,498. Do the majority of the people of the lower classes sleep on the floor without any beds?—They just put a mat or something like that on the ground.

21,499. How do you think that plague proceeds from an infected house to the neighbouring houses?—The process of dissemination seems to me to be this:—The poison in the system of a plague patient or of an affected rat or some such animal acts on the soil, if the soil is in a fit condition to be affected. Certain poisonous matter is then produced in the soil. The virulence of its infection seems to depend on the nature of the soil, and also, of course, upon atmospheric conditions. Persons who come into contact with such soil, and whose constitutions are not of a character to resist its power, come to be attacked. The infection seems to creep from the soil of one house to the soil of another, where the conditions are favourable. Affected rats, in many instances, carry the poison from the infected house to localities close by. Affected human beings carry it to longer distances, and thus form new centres of infection in congenial soils.

21,500. Have you had an opportunity of observing whether the infection proceeds by contact between human beings?—No, I do not think it does.

21,501. Or by clothes?—There were a few instances in which men who had come from Bombay were found to have brought the infection with them, though they themselves were not attacked.

21,502. Did you notice any affected rats in Poona?—Yes, several.

21,503. At what particular time did you observe them?—I specially saw them at the commencement of the epidemic.

21,504. In what months?—In September and October, particularly, I think.

21,505. Did you notice that plague was more virulent in any particular class of houses in the town than in others?—Yes. Generally, I found that houses which were damp, dark, and ill-ventilated were most exposed to the attack.

21,506. You are of opinion that the best means of dealing with it is to keep the patient away from the infected house?—Yes, the patient, as also the healthy inmates of the house. *Prof. G. K. Gokhale.* 23 Feb. 1899.

21,507. Have you had any opportunity of noticing the effects of disinfection?—I think so. Wherever these cases were discovered houses were disinfected, and it was then found that the infection did not spread to the adjoining houses; at any rate, not in the same rapid manner in which it had done so before.

21,508. Have the people here shown any objection to disinfection?—Yes, there is a natural disinclination to it.

21,509. Is this due to the feeling that it may destroy their property?—Partly. But there is personal disinfection as also disinfection of clothes.

21,510. Which do they object to?—They object to both, but personal disinfection is more disagreeable to them.

21,511. Are the people of a large town less inclined to move out into the neighbouring fields than the inhabitants of an agricultural village?—I should think so.

21,512. What are the reasons which would deter them from going out?—Their habits of life are such that they are not used to living in the open fields. Moreover, in large cities it is a costly thing to have huts put up, and many of the people cannot afford them. They are also afraid that their property, if left behind, would be stolen, and if they take it with them they are afraid of robbers.

21,513. Do you think that the people report the great majority of cases of sickness which occur in the town?—I think they do.

21,514. Before death takes place?—Yes. There may be a few cases where it is not reported, but, as a rule, they are now ready to report, because they know the advantages which they now secure by reporting.

21,515. How do you account for the great excess of deaths over reports of sickness?—Do you mean at present?

21,516. In the month of December last?—I was told that there was exceptionally heavy mortality among children, and that these cases were not reported.

21,517. Is your opinion based on facts?—I give you what I have heard.

21,518. (*Dr. Ruffer.*) Do you have many houses of two and three storeys in Poona?—Yes.

21,519. On what facts do you base your opinion that people in the upper storeys did not get plague so much as people on the lower floor?—For four or five months I was going about with the search parties. We found that most of the cases which occurred were on the ground floor.

21,520. Do the poorer people live on the ground floor?—Yes, as a rule. In fact, they live in houses which are only one storey.

21,521. Are the ground floors more crowded than the upper floors?—I think so.

21,522. Is there more ventilation on the upper floors?—Yes.

(Witness withdrew.)

Mr. Vishnu Anant Patwardhan called and examined.

21,523. (*Mr. Cumine.*) I believe you are a Municipal Commissioner?—Yes, at present. I was not during the epidemics. I received a letter from Sir Andrew Wingate stating that Government desired me to give evidence. *Mr. V. A. Patwardhan.*

21,524. You have come to tell us about the city of Poona during the second outbreak of plague?—Yes.

21,525. Have you lived long in Poona City?—Yes, for more than 30 years.

21,526. Which were the plague operations with which you were connected?—(1.) The house-to-house visitation by soldiers and volunteers in search of plague cases. (2.) The segregation and quarantine camp at the Sawar's Gate. (3.) The disinfection and detention camp at the Poona Railway Station. And latterly I have been serving as a Chief Volunteer in charge of one of the wards into which the city has been divided for plague administration.

21,527. Will you tell us what lesson the experience of Poona especially impressed upon you?—When the plague broke out for the first time in Poona, no one knew exactly what measures to adopt, and every step that was suggested as possible to help the suppression

Mr. V. A. Patwardhan.

23 Feb. 1899.

of plague was adopted. The people were new to these measures. They were panic-stricken and they considered these measures to be more horrible than plague itself. The result was the concealment of plague cases *which helped the spread of the disease.* No plague measures should, therefore, be so severe that people will try to evade them. The maximum of efficiency should be sought for with the minimum of inconvenience to the people. The experience of Poona has fully taught us that it is with the co-operation of the people themselves that this end can best be secured.

21,528. Will you tell us what has been done in Poona during the last few months to prevent the re-infection of the town?—The whole city is divided into 16 wards. A native gentleman called a Chief Volunteer is entrusted with the sole business in connection with plague in that ward, and a European officer supervises his work. The Chief Volunteer finds out native gentlemen to co-operate with him voluntarily, and one to be in charge of each sub-division. A complete census of each house in the ward is taken and is kept corrected up to date. The householders are required to report all new arrivals, all departures, every illness, and every death. They have also been required to report the appearance of dead rats in any house. The volunteers in charge of each sub-division visit each house once a week to check the census. All new arrivals by rail or road are required to report themselves at the Ward Office, and are kept under surveillance for 10 days, that is, they are required to present themselves at the Ward Office every alternate day during this period, and their names are entered in the census if they stay longer in the city; but persons leaving Poona during this period are freely allowed to go. No one on the census list can go by rail or road without a pass from the Ward Office, and no one can arrive by rail and enter the city unless he is vouched for by some volunteer, and information as to the locality he comes from, and the place where he will put up on arrival, is furnished. If any passenger, released on surveillance, fails to appear at the Ward Office, the gentleman (volunteer) who vouched for him is called upon to produce him or to explain for his absence. Every illness is to be reported, and a Plague Medical Officer is to examine the sick person and certify to his illness. If any illness which is not previously reported turns fatal, the inmates of the house are kept under surveillance for 10 days. No corpse can also be removed from the house until examined by a Plague Medical Officer. In this way a watch is kept over every individual inhabitant, and any case of plague, indigenous or imported, is brought to notice within a short time. The sick person is then at once removed to hospital, the inmates of the house are kept under surveillance, and they are asked to vacate the house for disinfection. The first cases of sickness are thus detected, isolated, and effectively dealt with, and are not allowed to grow into so many different centres for dissemination of plague. Had this very thing been done in December and January 1897, when we had imported plague cases from Bombay, we would have probably had no epidemic at all, or we would have at least considerably arrested its growth.

21,529. Have you any figures to put in to show us how this organisation protected Poona?—From July 1898 to the end of January 1899 there were in all 28 cases of plague, 4 of which were indigenous and 24 imported. In each of these cases the measures I have described were taken, and we believe that those measures prevented each of those cases becoming a plague centre.

21,530. Do the inhabitants of Poona city themselves appreciate the importance of this organisation?—All plague restrictions are, of course unpleasant, but the people realise the necessity that they must choose the less of the two evils. I believe that people have learned the value of these measures.

21,531. Has the late infection of Poona been due to a Poona person or an outsider?—It is due to an outsider, a Bombay man, residing here for a short time, and having frequent communication with Bombay.

21,532. Was not the person in whose house he lived to blame?—The house was vacant and this man hired it, but we do not know whether the owner of the house looked after it and knew of this, and the consequent illness, &c.

21,533. Have you noticed during the first outbreak that one particular part of the city was affected and during the second, another part?—Yes. During the first outbreak the eastern part, and during the second the western part, were particularly affected. It was a remarkable feature in these outbreaks, that while the disease was seriously raging in the eastern part, only stray cases occurred in the western part, which did not form centres of infection; and that while it raged in the western part only stray cases occurred in the eastern part. In some instances, houses which were affected at the first outbreak were also affected at the second.

21,534. Have you any figures with regard to that?—Yes, I have figures only for three Pets which formed the western part. In Narayan Pet, from January to May 1897, there were 27 cases and 21 deaths; in Sadashiv Pet there were 96 cases and 79 deaths, and in Somwar Pet there were 82 cases and 60 deaths. That was during the first epidemic. During the second epidemic, that is, October, November, and December 1897 to January and February 1898, in Narayan Pet we had 195 attacks and 169 deaths, in Sadashiv Pet we had 544 attacks and 429 deaths, and in Somwar Pet 317 attacks and 260 deaths.

21,535. Where do you think the poison lies in an infected town?—My impression is that there is something wrong in the soil of the infected house. I also observed, looking to the situation of the houses, that the poison appears to pass or be carried from house to house.

21,536. Have you noticed on which floor people are affected most?—On the ground floor. I have prepared a statement for houses in the Narayan Pet, and there you will find a number of small blocks of houses affected. I have myself gone over these—I know the locality.

21,537. Will you tell us your deductions from it?—That a block of houses becomes infected, and when there is a patient in one house my impression is the poison passes along or is carried to and infects the soil of the next house. I say the soil, because I find that in hospitals and segregation camps and so on the soil is not affected, and no amount of contact affects the other persons, but it is the residence in an affected area itself which communicates the contagion. If there is one case in one house and the people continue to reside in that house, it is my experience that other cases follow in the same house.

21,538. How do you think the infection spreads from house to house?—In Poona the poison imported from Bombay grew in the soil of the affected houses and spread from house to house, *how* it is very difficult to say! Rats may be one of ths agencies which spread the plague. They are also the first to be affected, and they serve as a warning to human beings to quit the locality. I know of houses where dead rats were discovered and removed, but where no cases of plague occurred. These houses are, however, well built and well ventilated, and were occupied by fewer inmates after the appearance of dead rats. I consider that poison is not carried from person to person by mere contact, however close, but is imbibed by a person by residence in an affected locality, which is not sufficiently exposed to the sun and breeze. The experience at the several hospitals supports me in this belief. I know of cases in hospital as well as outside hospital, where sick wives and other relations were attended upon night and day, and not even the vomit of the patient on the body of the attendant affected the latter. Some of these patients recovered and some died. The very small number of fresh attacks compared with the total number of admissions in the detention and segregation camps also supports this view. Native volunteers who accompanied search parties and entered affected houses barefooted or even touched sick persons were in no way affected. I have a statement showing the number of fresh cases in the several camps and hospitals.

21,539. Will you tell us what those figures are?—In the railway station detention camp from the 13th February to the 13th May, 13,606 people were admitted, and there were only 23 attacks. In the Bhamburda health camp from December 1897 to May 1898 there were 8,282 admissions, out of which 4,807 were from

infected parts, 2,935 were from arrivals by road and 540 arrivals by rail; that was when the railway detention camp was not ready. There was only one plague case. Then in the Sawar's Gate segregation camp from the 12th March to the 12th June 1897, 3,461 people were admitted and there were only 41 attacks. At the Hindu Hospital the rule was that each patient was allowed to have one attendant. There were 104 patients and an equal number of attendants, and among those attendants there were only two cases during the first outbreak, that is from the 15th March to the 31st May 1887. During the second outbreak from the 1st October 1897 to the 15th March 1898, 533 patients were admitted with an equal number of attendants, and among the attendants there were two cases, and two amongst the establishment, which numbered 57. In the General Plague Hospital from the 1st June 1897 to the 31st March 1898 there were 4,138 patients, and I take, as before, an equal number of attendants. No case of illness is reported among the attendants, but only among members of the establishment. There were 376 persons employed, out of which 26 were attacked.

21,540. Do you consider isolation of the sick to be necessary?—I consider the isolation of the sick to be necessary in the interests of the patient himself. If the locality of the house is affected, the patient has less chance of recovery by continuing to reside in the same house. Few people who continued in the same house recovered; while the non-removal of the first case led to several other cases in the same house. Instances of this can be given in numbers. Also about 20 to 30 per cent. of the cases which were removed to hospitals recovered.

21,541. What is your opinion of the importance of the evacuation of infected houses?—Evacuation of the affected house is also necessary in the interests of other inmates. Wholesale evacuation is highly objectionable especially in the monsoon and cold weather. If the persons who came in close contact with the patient leave the affected house that is quite sufficient. Where they should go is a question. I do not think all such persons, high and low, should be segregated at one place, as was done in the Poona segregation camp. Well-to-do, middle and upper class people, though they were willing to make their own arrangements to segregate themselves effectively, were not allowed to do so. If rich people go and occupy their garden houses, and if others go to reside in other vacant houses in an unaffected locality, I think they should be allowed to do so, provided they agree to remain under daily surveillance and medical examination at any of the Ward Offices. As to the lower classes, unless you provide accommodation for them, evacuation is a misery to them. They suffer by exposure to heat and cold, to which people living in crowded houses in a city are not accustomed. Inmates of neighbouring houses should be asked to vacate only in those cases where it is absolutely necessary to do so, but they need not be carried to health camps outside the city. They should be permitted to reside elsewhere in the city. If they are kept under daily surveillance for 10 days, that will be sufficient.

21,542. What have you to say about suspicious cases?—In suspicious cases the inmates were segregated even before the case was declared to be one of plague, and they had to undergo the pangs of segregation for nothing. This should be avoided. I have noticed in my own experience that a person who was subsequently found to be suffering from syphilis was removed as a suspicious case, and the inmates were then and there segregated and had to remain in the segregation camp for ten days.

21,543. You do not say, do you, that all the suspicious cases turned out not to be cases of plague?—No, what I mean is unless a case is declared to be plague the inmates should not be segregated. If we have a complete census of the locality we know who the inmates are and we can get hold of them, and when a case is declared to be plague they can be segregated.

21,544. Do you think that one central Plague Hospital is enough?—No. The ward hospitals, as in Bombay, are more suitable. We are naturally averse to remove our sick to hospital, but if a hospital could be provided for in the ward itself the *opposition of the people would be reduced and concealment of the plague cases would be discouraged.* If a separate house could be secured close by for segregating the contact people, so that they could frequently visit their sick and attend upon them, it would be all that could be desired. People in general have no faith in hospital treatment, and especially a central hospital as in Poona. The extreme desire of the people to go to their caste hospitals supports me to some extent in this view. In Poona the hospital and the segregation camp were at the two extremities of the town, one to the north and one to the south, which caused extreme inconvenience and irritation. The patient died in hospital and his relations did not even know of it in the segregation camp. Such a state of things is most repugnant to native feeling, and the remedy is to have the hospital and the segregation camp close to each other.

21,545. You attach great importance to this point?—Yes.

21,546. What have you to say with regard to disinfection?—On this point I am not in a position to give any decided opinion, because disinfection of houses was carried out, but I have something to say on the other side. Several dead bodies were found on the roads, and several deaths were reported which could not be traced as having occurred in any particular house, in which cases no disinfection took place either of clothing or anything else. These very clothes were, of course, used again, and my general impression is that the people continued to occupy those houses with safety and even used the clothes.

21,547. I thought you said it could not be found who the people were?—It could not be found to what houses they belonged, but they must have been residents of Poona. They must have belonged to some house, and my impression is that the people removed the dead body in order to free themselves of the consequences which would follow reporting the case. In those cases the houses could not be disinfected. Disinfection of affected houses was carried out with particular attention. Well-ventilated, spacious houses, exposed to heat and sun, which were surrounded by affected houses, could not have escaped the contagion. They were in several cases vacated and locked, or in some cases occupied by a few servants and others. They were not disinfected, and yet no cases occurred in them; and they were re-occupied with safety. What seems necessary is merely evacuation and exposure to the sun and air for some period. If the inmates desire to re-occupy the house early, it is safer to disinfect it and allow it to dry before it is re-occupied.

21,548. What sort of houses, in your experience, were the ones most affected?—My experience at the time of the house-to-house visitation showed that most of the houses affected were either old buildings with moist floors, or ill-ventilated and with insanitary surroundings; and in such houses more cases than one occurred, while the number of houses which were marked affected, but which were spacious and well-ventilated, was very small, and it was very doubtful whether they were at all affected. Out of 486 houses in Narayan Pet 84 were were affected, and out of them only about eight or 10 were good buildings. I have prepared a statement of these 84 houses which gives particulars, as follows:—

Mr. V. A. Patwardhan.

23 Feb. 1899.

STATEMENT of affected HOUSES and their CONDITION with DATES of ATTACKS from September 1897 to March 1898 in NARAYAN PET WARD, DIVISION Number XIV., POONA CITY.

Serial No. of House.	Dates of Plague Attacks from September 1897 to March 1898.				Total No. of Attacks.	Remarks as to Condition of House and other Special Particulars.
4	14.10.97	1.12.97	—	—	2	No plinth, has ground floor only, old rotten house, house occupied by Dhobis.
5	23.10.97	4.11.97	—	—	2	Has plinth in front but outside rotten, has ground floor, inhabited by Mahrattas, who make tin pots.
7	10.11.97	—	—	—	—	Rickety shed, as used for cattle.
10	2.11.97	—	—	—	—	Has no plinth, occupied by goldsmith, not ventilated.
14	11.11.97	—	—	—	—	One storeyed, is a good building.
22	29.10.97	—	—	—	—	Damp soil, no ventilation, old building, front part temple, back part used as residence.
23	11.12.97	—	—	—	—	Is gymnasium.
26	12.12.97	—	—	—	—	Rotten building used as a cattleshed, recently rebuilt.
27	7.12.97	—	—	—	—	Rotten building, extremely dirty, no plinth.
30	27.12.97	—	—	—	—	Milkman's house, used as cattlesheds.
31	27.12.97	—	—	—	—	
35	1.12.97	2.12.97	17.12.97	—	3	Narrow space, a building of two Khans adjoining a garden. Old building ill-ventilated.
36	21.12.97	—	—	—	—	Residences of milkmen, no plinth. Extremely dirty sheds.
37	18.11.97	—	—	—	—	
54	8.12.97	—	—	—	—	No ventilation, moist floor.
69	30.11.97	15.12.97	—	—	2	There was no ventilation, windows made by Municipality recently.
90	4.11.97	—	—	—	—	Old ricketty building, moist, adjoining river.
93	7.12.97	—	—	—	—	No ventilation, no plinth, old building.
98	31.10.97	—	—	—	—	Stables, one-storeyed.
111	7.12.97	—	—	—	—	Old building, ill-ventilated, moist floor, dirty surroundings.
112	28.10.97	—	—	—	—	Temple, good building.
121	5.12.97	—	—	—	—	Overcrowded. A small wretched and close building without light and plinth.
135	30.11.97	—	—	—	—	Overcrowded chawl, and occupied by shoemakers, surroundings dirty and unhealthy.
142	5.10.97	—	—	—	—	Very dirty house adjoining river, moist floor.
154	13.11.97	—	—	—	—	Extremely wretched building, moist floor.
184	10.11.97	—	—	—	—	Ill-ventilated, no plinth.
197	14.11.97	—	—	—	—	Shoemakers' building, ground floor only.
206	22.11.97	—	—	—	—	No plinth, moist floor.
234	12.11 97	—	—	—	—	The old house destroyed and new one built.
235	10.11.97	—	—	—	—	No plinth, ill-ventilated.
250	27.12.97	13. 1.98	—	—	2	Adjoining garden, ill-ventilated.
253	7.12.97	—	—	—	—	No ventilation, no plinth.
262	12.10.97	19.10.97	4. 1.98	—	3	Overcrowded. Row of shops in front, old rotten building, moist floor.
265	12.12.97	—	—	—	—	Moist floor.
300	10.12.97	—	—	—	—	Old ricketty building, extremely dirty.
302	19.12.97	—	—	—	—	Sweeper's house.
321	4. 1.98	—	—	—	—	Windows opened by Municipality recently.
323	22.12.97	—	—	—	—	Old rotten house.
333	10.11.97	—	—	—	—	A row of four rooms on the ground floor, adjoining a garden, no ventilation and no plinth.
340	10.11.97	—	—	—	—	There was no case in this house. A patient in the Plague Hospital wrongly gave his address in this house. It was marked as affected, and the segregating party broke open inner doors and boxes and cupboards to search contacts. The owner had left for Berars and a servant was kept to watch. It is a newly-built and substantial building.
347	14.12.97	—	—	—	—	A close house without ventilation or light, and inside dirty.
348	12.12.97	—	—	—	—	A good building, proper ventilation.
349	5.12.97	—	—	—	—	A temple, a good building, clean, newly-built house; contagion caught in No. 362, opposite, the house on the other side of the road.
353	11. 1.98	—	—	—	—	A washerman's house, a wretched row of rooms on the ground floor, moist and dirty.
357	9.12.97	—	—	—	—	An old ricketty building without plinth, not well ventilated.
362	6.12.97	7.12.97	9.12.97	10.12.97	4	An old building on the ground floor, moist, not well ventilated.
363	21.10.97	—	—	—	—	Not a good house; vegetation in the rear.
365	23.10.97	23.10.97	—	—	2	Overcrowded. An old house, rooms on ground floor well ventilated, part one-storeyed, ricketty.
367	30. 7.97	—	—	—	—	An old ricketty house, moist and dirty.
368	10.11.97	—	—	—	—	Moist floor, rooms on ground floor, ill-ventilated, recently holes made by Municipality in the house.
369	18.12.97	—	—	—	—	A good building, well ventilated, but is connected with 367.
371	31.10.97	5.11.97	—	—	2	Barber's house, surrounding is dirty.
372	6.11.97	—	—	—	—	A narrow house, dirty, ill-ventilated, moist floor.
374	29.11.97	—	—	—	—	An old house without any ventilation.

Serial No. of House.	Dates of Plague Attacks from September 1897 to March 1898.					Total No. of Attacks.	Remarks as to Condition of House and other Special Particulars.
376	18.10.97	—	—	—	—	—	An old ricketty house, rooms on ground floor moist floor inside below the level of the road.
383	20.10.97	21.10.97	25.10.97	27.10.97	30.10.97	16	An extensive ground, let out on ground rent, where poor people have built rows of ricketty small houses on the ground floor, without any plinth, without any drainage; very dirty. After a few cases the inmates dispersed, but, when affected outside, came to die in their own houses. Hence the large number of attacks At the first outbreak no cases occurred in these houses. Was overcrowded.
„	30.10.97	31.10.97	2.11.97	5.11.97	6.11.97		
„	6.11.97	8.11.97	8.11.97	10.11.97	15.11.97		
„	25.11.97	—	—	—	—		
390	2.11.97	6. 1.98	—	—	—	2	Dirty surrounding.
391	29.11.97	—	—	—	—	—	Old ricketty rooms on ground floor, ill-ventilated moist floor and surroundings dirty.
392	22.10.97	—	—	—	—	—	
398	16.11.97	—	—	—	—	—	Ill-ventilated, moist floor, narrow, one-storied building without open space, waste water drained through floor of house to the front road.
400	29.10.97	—	—	—	—	—	
402	21.10.97	22.10.97	—	—	—	2	An old building.
404	12.10.97	—	—	—	—	—	Milkman's house, used for cattle; inside dirty and ill-ventilated.
407	20.10.97	20.10.97	—	—	—	2	An old house, close, moist floor, one-storeyed.
409	14.10.97	—	—	—	—	—	Ground floor, extremely moist, ill-ventilated inside, no plinth, one-storeyed, old house.
412	5.11.97	—	—	—	—	—	Inside extremely wretched, moist floor, without light or ventilation; outside, one-storeyed ground building.
418	24.10.97	—	—	—	—	—	
420	9.11.97	—	—	—	—	—	An old one-storeyed house where casees occurred on the upper floor, ground floor moist.
421	13.11.97	—	—	—	—	—	An old overcrowded house, ill-ventilated, moist floor.
430	24.11.97	—	—	—	—	—	A part of the house old, and part newly built and well ventilated.
434	4.11.97	—	—	—	—	—	Ill-ventilated, surrounded by houses on both sides.
443	12.11.97	14.11.97	—	—	—	2	Ill-ventilated; inside, dirty and moist, rooms on ground floor in the rear, waste water drained through the ground of the house; outside, open and one-storeyed house.
448	26.11.97	3.12.97	5.12.97	12.12.97	13.12.97	5	House of a milkman, old rooms on ground floor moist, close to a garden. Cattle sheds.
449	31.10.97	31.12.97	—	—	—	2	Overcrowded. An old ricketty building on ground floor, moist and dirty.
454	30.10.97	—	—	—	—	—	Old house, no proper ventilation.
461	12.12.97	—	—	—	—	—	Old house, no plinth.
465	20.10.97	—	—	—	—	—	On the same level with road, moist floor.
466	7.12.97	—	—	—	—	—	No plinth.
472	9.11.97	—	—	—	—	—	A close house surrounded on all sides by houses, extremely moist floor, one-storeyed, without plinth.
473	4.11.97	25.11.97	—	—	—	2	A ricketty chawl, moist floor. Overcrowded.
477	30.11.97	—	—	—	—	—	New building, proper ventilation.
480	12.11.97	—	—	—	—	—	Old one-storeyed house, moist floor.
481	9.11.97	—	—	—	—	—	Good ventilated house, no plinth.
484	1.11.97	—	—	—	—	—	Very good building, ventilation proper, inmates say that there was no case in the house, occupied by a native doctor.

The floors are without any plinth, and moist during the monsoon and so on. Generally the houses had insanitary surroundings. In this very Pet 74 deaths could not be traced to any particular house, but my impression is that they must have been residents of the locality.

21,549. What have you to say with regard to corpse inspection?—Examination of corpses was strictly carried out. It ensured correct registration of deaths from plague, and enabled the authorities to trace out every affected locality where a plague death had occurred. In some cases the examination was delayed for several hours. With us, the dead body is to be removed from the house to the cremation ground as early as possible. But if a death took place at 10 p.m. in the night, the dead body had to be kept in the house till 10 a.m. next morning, to allow of its inspection by the Plague Medical Officer. This delay in the examination of corpses caused great annoyance. Corpse inspection is a necessary measure in times of a plague epidemic, but arrangements must be made for examination at all hours of the day and night. It is a necessary measure, but it should be carried out with as little inconvenience to the people as possible.

21,550. What do you think is the necessity for the measure?—If people conceal plague cases or do not report illness, that is a test by which we can ascertain even after death if there are signs of plague. I believe if every corpse is inspected there is a great guarantee of every plague case being detected.

21,551. Who do you think should have the duty of disinfecting and limewashing the houses?—I think that might be left to the owners themselves. If a rule were framed in Poona to that effect, we could very effectively carry it out by providing simply somebody to supervise that the work is done properly. If it were left to the people themselves, they would do it more carefully and willingly in their own houses.

21,552. Is there any other point you wish to lay before us?—Yes. I think that the plague measures should not be enforced equally in all cases. Captain Lockhart Mure, under whom I am at present working, made it a point to make certain exceptions in particular cases, modifying the rules. At the railway station he exempted high-class people from the disinfection of clothing and person, and even in the case of surveillance he allowed some, I believe, to be exempted altogether, and others were only asked to appear on the first and last days of the 10 days. They were, of course, educated people. I think that discretion should be used in enforcing the rules.

21,553. (*Mr. Howett.*) When the plague broke out at Poona, was there a byelaw of the Municipality requiring deaths to be reported?—Yes, there was.

Mr. V. A. Patwardhan.
22 Feb. 1899.

21,554. Was that byelaw allowed to fall into disuse?—Even after the enactment of the byelaw the procedure was that the Municipal Inspectors of the different wards and the sweepers made inquiries of deaths and reported, or the constable at the nearest police station, who got information, reported it.

21,555. Did the byelaw impose the obligation on the householder?—Yes.

21,556. Was it enforced against the householder?—I think not.

21,557. (*Mr. Cumine.*) Is there any penalty for not reporting cases of sickness, at present?—Of course, the notification issued provides that people who fail to report will be prosecuted, but as a matter of wisdom this rule is not enforced, because, in plague matters, the officers do not like to go to the extreme with regard to prosecution. These measures are against the ordinary habits of the people, and although the people have to submit to them, the officers do not go to great lengths in the matter.

21,558. Is there any advantage held out to people to report cases of sickness?—Yes.

21,559. What is the advantage?—From June 1898, it was a rule that, if illness was previously reported and death ensued, the people were not put to any inconvenience, they were not segregated, nor even kept under surveillance, but if death occurred, and the people had not previously reported the case, they were kept under surveillance for 10 days.

21,560. Was that carried out?—Yes, for a time, until we had the present epidemic.

21,561. (*The President.*) You say in your précis, "It "is said that the inmates of the affected localities "should not be allowed to run over the whole place. "There is much truth in this." What is the truth?—It is likely that some of them might carry the germs of contagion with them, and though a small percentage, still some of them might develop plague.

21,562. Then that may altogether destroy some other measures which you may adopt by their spreading the infection all through the town?—The percentage of such infections, as shown by the results of the segregation camp, is so small that I propose that instead of taking them to the segregation camp they might be kept under surveillance, and if you could watch them for 10 days you could pick out any case which developed plague.

21,563. But the information you get with regard to sickness appears to be very imperfect?—But we should have the people under surveillance, which means they would have to report themselves every day to the Ward Office for medical inspection by the Medical Officer, or, in the absence of the Medical Officer, by the Ward Officer. That would be a guarantee that they would appear for inspection every day. In case they did not, we could find out what the cause was, and if there were any cases of plague we could take them to the hospital.

21,564. In those houses of the worst character which you refer to, where the plague was most prevalent, was there most overcrowding?—In some of the houses, but not all.

21,565. Are they the localities where overcrowding is most prevalent?—Yes, they are. There is a chance of more cases occurring in those houses, and I have noticed one or two houses where more cases occurred owing to overcrowding.

21,566. With regard to corpse bearers, do you find that they have been infected by bearing corpses?—I am not personally aware of that.

21,567. You have heard of no cases?—No, not where they were affected. But even if they were, there is one fact which we must bear in mind, and that is that usually the relations and neighbours of the deceased come to carry the corpse. If there are relations amongst, them it is very probable that their death might be due to the original contagion they carried, and not necessarily from contact with the corpse.

21,568. You mean they might have become infected by coming in contact with the patient during life?—Yes.

21,569. You do not know of any instances in which direct infection appeared to be conveyed by carrying the corpse?—No. Mere contact is not sufficient to carry the contagion in my opinion.

21,570. (*Prof. Wright.*) Do you think any bodies are surreptitiously buried?—There was one case in the Sadashiv Pet where a dead body was reported to have been buried privately. It was found out and the man was prosecuted and punished.

21,571. Is it difficult to escape corpse inspection?—Yes; this was very early in the first outbreak.

21,572. Do you think it is difficult now?—I do not think any corpse could be surreptitiously buried now.

(Witness withdrew.)

Rai Bahadur B. C. Sathe.

RAI BAHADUR B.C. SATHE called and examined.

21,573. (*Mr. Hewett.*) You are a retired Deputy Collector living here?—Yes.

21,574. Were you employed in any plague duty in any of these epidemics?—Yes; I was employed as a volunteer in the ward in which I reside, that is the Sadashiv Pet.

21,575. During both epidemics?—In the first epidemic I served simply as a volunteer, but during the second epidemic I did a good deal under the Superintendent of the ward.

21,576. What were your duties during the second epidemic?—I was there to collect other volunteers to go round the Pet with the military to find out sick cases, to superintend disinfection of the houses, to report cases of sickness, also to report when corpses were found, and generally to do any work which was told to me by the Superintendent.

21,577. Are you at present employed on that duty?—Yes.

21,578. In reporting cases of sickness?—Yes, searching houses for sick persons, reporting them, and also, if necessary, looking after conservancy on the premises.

21,579. Had you any opportunity of observing how Poona got infected the second time?—During the second epidemic, the Kirki people came to Poona without any restriction and brought the infection.

21,580. Did you find the same places get infected in the second epidemic as in the first?—At first it was rather peculiar. The places which were secure from the first epidemic got the second epidemic at first, in that part of the town which was considered to be fairly clean

21,581. Did you notice that any houses which were well ventilated, and of good structural condition, had plague cases in them?—That is my humble opinion, especially with reference to a particular part of the town, namely, the south-western portion of the town somewhat near to the river.

21,582. Do you mean that in the south-western portion of the town some good houses were attacked?—Yes.

21,583. Is that the part of the town in which the best houses are?—I would not call them the best houses, but they are in the best locality, I should say. The houses are of an ordinary nature, but they are on a raised platform and have sufficient air and light, having back and front verandahs, and there the infection for a time raged very high.

21,584. Were they private houses or lodging houses?—In some of them the owners lived with lodgers also. We have very rarely different lodging houses and private houses; they are all jumbled up together.

21,585. Did the people show a dislike to leaving the town and going to camp?—They did not. As far as they could, they left *en masse*. At least, three-quarters of the Sadashiv Pet people ran away to different places. I have locked and sealed very many houses in Sadashiv Pet where they were kept vacant by the owners.

21,586. You did not find them averse from leaving their houses?—When they found it convenient to go away voluntarily they went away.

21,587. Do you mean that they did not like to go away if the plague authorities suggested it to them?—When people of their own free will could make proper accommodation for themselves they went outside, but when

they found their means not sufficient to do what was necessary outside they were reluctant to go.

21,588. Were the great majority able to make arrangements or not?—The great majority were able to do it.

21,589. Did you disinfect the houses in which plague cases did not occur as well as those in which plague cases did occur?—In Sadashiv Pet all the houses were disinfected.

21,590. Do you think that is necessary?—As it was carried out during the second epidemic the disinfection consisted of two portions. The first was disinfection with some mercurial liquid, and no one will object to that. But secondly there was disinfection by the spreading of quicklime on the floor, and most people objected to that very much. Although I cannot pronounce any scientific opinion about it, yet I say from experience that our people in their own houses, and all children, go about without any covering on the feet, and the spreading of lime over the floor keeps the feet burning for a number of days. The people very much objected to that, but they did not care about the liquid.

21,591. Do you think that it is unnecessary to disinfect a house adjoining a house in which plague has occurred?—I think the solution is all that is necessary. I think that the quicklime is not necessary unless the house is very bad.

21,592. I understand you to mean that houses where cases of plague have not actually occurred, but which adjoin such houses, should be disinfected, but that it is sufficient to disinfect them with perchloride of mercury?—Yes.

21,593. Did any instance come to your notice in which after a house had been thoroughly disinfected the people re-occupied it and cases of plague recurred in it?—I am sorry to say that in Sadashiv Pet such cases may have occurred, but I cannot remember that at this moment, because as soon as there was a case so many people left the place and did not turn up for a couple of months.

21,594. Do the great majority of the people here sleep on the floor or on beds?—Many of them sleep on the floor with hardly a mat.

21,595. Do you find the people are now ready to report all cases of sickness?—My own impression is that they have got thoroughly used to the system which has been prevailing for the last six months, and that they always do their utmost to report cases to the office.

21,596. How many cases of sickness have been reported in your own ward during the past week?—I think about 8 or 10.

21,597. How many corpses have been examined during the same week?—About 10 or 12 were inspected.

21,598. Then all the cases of sickness were not reported?—I will tell you how it was. Some of those sick cases were considered to be suspicious, or thought to be plague cases, and some of them were removed to the hospital, and when the fatality took place in the hospital we had nothing to do with it.

21,599. Do you only report severe cases of sickness?—No; all cases of sickness that come to our notice are reported and we leave it to the Medical Officers to decide whether it is or is not a plague case.

21,600. What is the population of your ward?—I believe about 5,000 or 6,000.

21,601. It is very healthy if there are only 8 or 10 cases of sickness in the course of a week, is it not?—I believe we have enjoyed a pretty good time during the last five or six months.

21,602. (*Prof. Wright.*) Were any of those 8 or 10 cases plague cases?—In the last week there were some plague cases.

21,603. Then you ought to add to the corpses which have been inspected also the corpses of those who died in the hospital?—We have nothing to do with the corpses of people who died in the hospital.

21,604. But if you added those to those which you examined in your ward you would have more dead bodies than cases of sickness, would not you?—Yes.

21,605. (*The President.*) Were there many cases of plague in the second epidemic?—There were very many cases in the second epidemic in the ward to which I belong.

21,606. How many?—I think about three or four hundred or even more.

21,607. Between what dates was the mortality very high?—From the 12th September 1897 to the 7th February 1898.

21,608. What ward was is it you refer to where the houses are in good condition?—I refer to my own ward, the Sadashiv Pet ward.

21,609. Are all the houses in good condition there?—I think most of them are in fair condition.

21,610. There are no bad houses?—Very few.

21,611. They are a better class of people?—Yes.

21,612. Did many slight cases of plague occur in any one individual house?—There have been some such houses where three, four, five, and six cases occurred.

21,613. One after the other?—Yes, and simultaneously sometimes.

21,614. In these cases where they occurred one after the other were the cases which first occurred removed? Were they removed one after the other from the house?—In some cases the first case was removed and the house disinfected. Then between that disinfection and the first attack another case cropped up which proved fatal. Then that case was removed. Sometimes when these cases were going on unfortunately these was a third case fatal at once, perhaps through fright. The people in most cases got it because they lived in a close atmosphere and in very small rooms.

21,615. Could you give us a statement of the houses in which plague occurred, showing the nature of each house, the total number of people living in each house and the number of rooms, and including the kind of floor and the means of ventilation?—Yes. I have prepared two statements of all the houses affected, giving the above particulars, and these may be abstracted as follows:—

——	Number of Houses.	Average Number of Persons in each House.	Average Number of Persons attacked.	Average Number of Deaths.	Nature of Ventilation.	Kind of Floor.
Class I. -	70	16	2	1·4	1 fair, remainder good.	Mud.
Class II. -	113	14	1·8	1·3	4 fair, remainder good.	Mud.
Class III. -	81	12	1·7	1·4	1 fair, remainder good.	Mud.

21,616. Have you anything else to say?—I would like to bring to the notice of the Commission one thing with regard to locomotion by railway. In the matter of locomotion there was a great cry all over the place that there was no uniformity of procedure adopted. For instance, things which were considered sufficient by the Poona authorities were not considered sufficient by the neighbouring district authorities or Native States where the Political Agent's will was supreme. In fact, the rules with reference to locomotion varied in each district, and consequently people who were obliged to travel from one place to another were placed in an awkward position, not knowing whether it was safe for them to travel or not. In many instances I have found people who wanted to go to a place and come back within two or three days, who did not know whether it was possible for them to do the journey within the specified time because at the place they were going to there were certain rules against which they could not guard themselves beforehand. What we all wished was that anything which might pass with one authority, might also part with another authority, unless in the meantime the circumstances of the traveller undergo a change.

21,617. You have found the differences very inconvenient to travellers?—Yes.

(Witness withdrew.)

Assist. Surg. E. S. Bharucha.

24 Feb. 1899.

Assistant-Surgeon E. S. Bharucha called and examined.

21,618. (*The President.*) You have had hospital experience, I think?—Yes, partly hospital, and I was also in charge of the Flying Column No. 4 at Kaledhon in the Satara district.

21,619. (*Prof. Wright.*) Where were these flying columns equipped?—There were about eight columns and they were organised in Bombay. My column was No. 4.

21,620. Was the column organised when you took charge of it?—No.

21,621. Then you had to do the organization yourself?—Yes.

21,622. Who were the men in your column? How was the gang recruited?—I was the head of the gang, and under me there were three Hospital Assistants and three medical students from the Byramji Jeejeebhoy Medical School, Poona.

21,623. How many men were there in the gang?—Besides the above we had six sweepers and a dozen coolies, and, in addition to that, more than 50 men locally obtained direct from the place.

21,624. Were you supplied with pumps?—Yes.

21,625. What sort of pumps?—At first I had a few brass pumps, but afterwards I had a large supply of wooden pumps sent by the Surgeon-General.

21,626. How did you get the disinfectants?—I got them direct from Bombay by making requisitions from time to time on the Surgeon-General.

21,627. What disinfectants did you use?—We used in the early beginning phenyle and carbolic acid, because I found it locally there.

21,628. You had nothing with you when you began?—No. I was sent out from Poona without any notice. What I found there was a few brass pumps, phenyle and carbolic acid. These were supplied to me by the Collector at Kaledhon.

21,629. Do you know where they got that?—They must have got them direct from Bombay. On my going there I represented my requirements to the Surgeon-General and within a fortnight I received a full stock of instruments and disinfectants from Bombay.

21,630. How did you make up the disinfectant used by your gang?—I used to make it up with four ounces of corrosive sublimate and eight ounces of common salt which I obtained from the bazar, and added 30 gallons of water. I had wooden casks supplied to me which held about 30 gallons of water.

21,631. What strength does that make it?—Approximately 1 in 1,000.

21,632. Did the whole of the perchloride of mercury dissolve?—Yes, very nearly.

21,633. Did you take it out with you for your disinfection operations in that solution?—I used to have packets made up and sent round to all the different members of the staff. Each packet contained four ounces of the corrosive sublimate and eight ounces of salt which was dissolved in water in those casks. These casks were supplied from Bombay and they held 30 gallons of water.

21,634. Was it hard or soft water?—It differed, but in most places it was hard water.

21,635. Before you went down to Kaledhon I think there was cholera reported?—It was reported in Kaledhon and the district round about.

21,636. Do you think this cholera has any connection with plague?—I do not think so. My own belief is that most of those cases of cholera which were reported were, properly speaking, cases of plague. Nobody had an opportunity of seeing them; there were no medical men on the spot. It was an out-of-the-way spot altogether.

21,637. Is there any symptom of plague which might have been mistaken for cholera?—Not so far as medical men are concerned, but I think ignorant people could mistake it; or possibly it was returned as cholera in order to prevent the difficulties which would arise if plague were reported.

21,638. You think that any epidemic disease would be reported as cholera by the villages because they know that best?—I believe all these villages were reported as having cholera before plague, but no village which was affected after my taking over the charge was shown to have had cholera before plague.

21,639. You say in your précis that the evacuation of infected villages is very effective when it is carried out early; have you any instance in which evacuation was very effective?—Yes, I have instances where evacuation was carried on by the people voluntarily. One such village was Valuj.

21,640. Were you on the spot?—Yes.

21,641. When did you first get notice?—On the 16th October 1897, and I visited the place on the 17th or 18th October.

21,642. How many plague cases had there been?—Ten cases of plague had taken place before I went there. I believe plague was probably there two or three days earlier than that, but they were all discovered on the 16th. When I arrived there I was surprised to see the people had of their own accord gone out to live in the fields—almost the whole village.

21,643. How many inhabitants has this village?—Approximately about 800 people. I found it entirely empty with the exception of two or three village officers in charge.

21,644. Did the people go back into the village?—Not for a month-and-a-half.

21,645. Did not they go back from day to day to fetch things?—They were almost all agricultural people, and had very few wants. They took everything from their houses and lived in camp.

21,646. How many plague cases occurred after evacuation?—On the 16th and 17th there were 10 cases, and then there were no cases on the 18th, 19th, 20th, 21st, 22nd, and 23rd, not even in the fields.

21,647. How did you know there were no cases? Did you go round to the huts?—Not personally, but my assistants went round the huts. There was a regular searching carried out. On the 24th two cases were reported. These were in the same family which had been affected before. Then on the 25th another case was reported, on the 26th another; on the 27th there was no case, on the 28th there were three cases, and then practically the disease disappeared.

21,648. Did you stay on the spot until the 28th?—I was not in the same village, but I visited it every second or third day. I had a number of other villages to look after.

21,649. After the 28th you say there were no other cases?—There were cases, but I know how those cases occurred. A man had been living in the village who was one of the village officers and a Brahman. He was not an agriculturist, and did not know where to go, and he lived in the outskirts of the village. I believe he got his infection from the village. The second case which occurred after that was the man who attended on him.

21,650. And then did the plague epidemic stop?—Yes, there was no more of it. There were altogether 19 cases there. That is an example of a village where voluntary evacuation was carried out with good results.

21,651. Do you often find that buboes are small at the beginning of an epidemic?—Yes, even smaller than a betel nut.

21,652. Were these cases very severe?—Yes. Comparatively speaking they were more severe than those where the buboes were more marked. I have often observed that. They are almost invariably fatal.

21,653. Did you see any mild cases of plague, so-called *pestis ambulans*?—I have said in my précis that in one village an outbreak of mumps preceded an attack of plague, and this was also noticed by me in Poona. I was in charge of the observation wards of the Sassoon General Hospital there. From a particular house from 20 to 25 famine children were brought in—it was famine time then—all suffering from mumps. One of them afterwards developed characteristic symptoms of plague. She had mumps, and afterwards developed a bubo in the groin, and all the other characteristic signs of plague.

21,654. You have seen this also in the plague-infected villages, I understand?—In one village, Mahuli.

21,655. Was that at the beginning of the epidemic?—Yes; in fact, I diagnosed these cases as mumps at

the time, but I now believe they were cases of *pestis ambulans*.

21,656. Did these symptoms only occur in children?—In Poona only in children, but in my village they were in men, women, and children.

21,657. Then I believe you have seen an association of small-pox with plague?—Yes. This has come to my notice in three villages. In one village very near my headquarter station, named Chitale, about 14 cases of small-pox had taken place before plague occurred there. The early cases of small-pox were not seen by me, but by the vaccinator of the district, and he proposed vaccinating the remaining part of the population, but the people refused. Then in the same family where the last two or three cases occurred, I was told there were some cases of fever, but there were no signs of small-pox. I went to see them. I could not come to any conclusion, because these cases of fever which occurred were in the same family where the cases of small-pox occurred, and I thought they might be cases of small-pox without any eruption, although I had never seen such cases. I deferred the diagnosis until the next day, when one of the two suspicious cases died and the other developed a bubo. From that time onwards regular cases of plague were seen.

21,658. You say that sometimes the incubation period has extended to 14 days?—Yes, I have noticed it in a case in Poona. I believe this case was probably reported to you by Col. McConaghy in Karachi. It was a Parsee child who arrived in Poona on the 3rd December 1896. She came from the district of the Fort in Bombay where plague was then raging very fiercely. Thirteen days after that the child was doing well. On the 14th day I was called in to see the child about two o'clock in the afternoon, and she had a temperature of 104, which in the evening went up to 106.

21,659. When did the child get this temperature?—On the 17th December, the 14th day after arrival from Bombay.

21,660. Do you think the child may have had clothes on her which came from the infected district?—I do not know.

21,661. (*Dr Ruffer.*) Was there any plague in Poona at that time?—In the cantonment where the child was living there was no plague then. *Assist.-Surg. E. S. Bharucha.* 23 Feb. 1899.

21,662. Was there any plague in Kirki?—Long after that.

21,663. In the town?—There were suspicious cases beginning to come, but there was no reason to believe that this child had access to the city.

21,664. (*The President.*) With regard to those cases of mild plague which you mistook for mumps, was the swelling on one side or on two sides?—Sometimes on one and sometimes on both, in the parotid region.

21,665. Was it infective?—I considered them as infective, because there were so many other children brought from the same place. They all recovered, with the exception of the one who got the bubo in the groin. That case was transferred to the Plague Hospital and died there.

21,666. You think the duration of an epidemic may be greatly modified by the measures which are adopted?—Yes.

21,667. Especially by what measure?—I believe two measures are of the greatest importance, viz., early and complete evacuation if you can get early notice, and a careful searching of the fields and the removal of any plague case occurring in the fields to hospitals, and separating those people from the healthy. In the village of Lengre where this searching was not done very well, plague continued some time, so I had the fields searched under my own supervision, and succeeded in bringing out 10 cases in one day, whereas formerly only one or two cases where reported. For only two or three days after this cases came to be reported, and subsequent to this no more cases occurred, and the place up to date remains uninfected.

21,668. Can you give us an example in which the duration lasted for only a fortnight?—It lasted 16 days in one village named Chitale, and 21 days in the village called Valuj.

21,669. Were the measures there completely carried out?—Yes. In the village of Valuj there was voluntary evacuation.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Council Hall, Poona.

FIFTY-FIFTH DAY.

Friday, 24th February, 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

MR. C. J. HALLIFAX (*Secretary*).

Major W. L. READE, R.A.M.C., called and examined. *Major W. L. Reade, R.A.M.C.* 24 Feb. 1899.

21,670. (*The President.*) You are on Special Plague Duty here?—Yes.

21,671. As the Chief Plague Authority in Poona city?—Yes.

21,672. When did you assume this office, towards the end or at what time, relatively, to the first epidemic?—I came out originally in February 1897.

21,673. So that you can speak of the first epidemic?—I was here for several days at intervals during the first epidemic.

21,674. When did the first epidemic commence here?—It commenced here in December 1896.

21,675. Was it discovered how it originated?—I think there was very little doubt it was communicated from Bombay by train. I do not think that has ever been traced accurately, but I think there is little doubt it was by railway intercourse.

21,676. Would you give us an account of the first epidemic in Poona and the amount of the plague which occurred?—It was about the middle of February that measures were first taken for search parties and compulsory isolation of the sick in hospital.

Major W. L. Reade, R.A.M.C

24 Feb. 1899.

21,677. You are aware of the account* which has been written of the epidemic?—Yes. Dr. Lowson and myself were in an advisory capacity to the Committee. We used to advise the then Chairman of the Committee with regard to measures we thought necessary.

21,678. You adopt this account of Mr. Rand's as being an accurate account of the epidemic?—Yes, I have read it, and I take it as an accurate account.

21,679. Do you know when the first epidemic terminated?—It was over at the end of May 1897. There were a few dropping cases in May. Then during June and July occasional cases occurred. The total mortality, however, was heavy; it was accounted for by cholera, there was a cholera epidemic at the time.

21,680. When was Poona entirely free from plague after this epidemic?—There was an interval during June and July. With the exception of, I think, one case in July, it was practically free in June and July 1897.

21,681. When did plague again appear in Poona?—There were imported cases from Kirki in August 1897.

21,682. Did that constitute the commencement of a second epidemic?—Of course it is difficult to say whether it might have been what is called an indigenous outbreak. I have no evidence of that, but there was direct evidence that Kirki was infected, and we have direct returns of imported cases from Kirki.

21,683. Could you describe the course of this second epidemic, starting in August 1897?—There were four imported cases on the 30th July from Kirki. That was practically the start of it. Then there was one on the 1st of August, one on the 7th, and one on the 9th of August, and so on. Then it went up to an average of about one a day. Then the indigenous cases commenced, I mean the indigenous cases were above the imported cases, but during all that month of August we had continuous records of imported cases from Kirki.

21,684. What was the course subsequently?—I was not here during this time from August to September, I came here in October. On the 11th September there were 14 cases, then it went continuously upwards, and on the 20th November there were 400 cases a week. It reached its acme on the 11th December, and then from that day there was a continuous fall down to the end of February 1898.

21,685. Could you give us the total number of cases in this epidemic?—The total mortality from plague was 3,633, and the cases were 4,644.

21,686. What has been the history of plague in Poona since February 1898, when the epidemic you have just spoken of terminated?—Since February 1898 to February 1899 we have only had imported cases. The last week we have had a little outbreak in Sadashiv Pet from an imported case from Bombay, in which we have had the so-called indigenous cases, but which have resulted from the imported ones.

21,687. You remained practically free until this month?—Yes, until this month. We have had 30 cases in the last nine months, since the epidemic of 1898.

21,688. These were all imported cases?—Yes, all of them.

21,689. Are you in a position to state briefly what were the measures employed during the first epidemic?—Rigorous isolation of all the sick in hospital was carried out, compulsory detention of the contacts in segregation camps, and disinfection of houses and clothes, and there was an organisation of search parties by British soldiers and sepoys accompanied by native workers.

21,690. And the segregation was a partial one, as far as I understand?—It was compulsory detention in a segregation camp in the 1897 epidemic. Evacuation was not carried out in this epidemic. There were no health camps. From February 1898 to the present date observation of contacts has been carried out.

21,691. Is the rapid decline in the first epidemic, from December 1896 to the end of March or April 1897, coincident with any plague measures that were adopted?—Undoubtedly.

21,692. Which plague measures?—The measures which were brought into force, namely, the isolation of sick into hospital, and the segregation of the contacts.

21,693. There was a decline, and I understand you to say that took place after these measures had been adopted in the first epidemic?—There was, I think I might say, a continuous fall in the first epidemic.

21,694. What measures were adopted in the second epidemic?—In the second epidemic we relied more on the help of the native people, and we gradually lessened the strictness of the measures, and after a time we modified them more. We have done away with the compulsory detention of the contacts in a segregation camp, and we have lessened our measures quite recently with regard to hospital treatment, but I think the chief measure was the lessening of the strictness of our segregation system. We created a system of open segregation by which people were allowed out during the day, and they had to report themselves at night. We had a roll-call every morning.

21,695. Previously, they were kept in the camp?—Yes, in a guarded camp.

21,696. In the second epidemic how long were they segregated?—Ten days.

21,697. What was the treatment of the evacuated houses?—Thorough disinfection with perchloride of mercury.

21,698. To what extent was evacuation carried out? What was included in the evacuation in the second epidemic?—In the second epidemic we rarely disinfected more than one house unless we had some evidence to show that the adjoining houses had been contaminated. We judged each case on its merits, and if there was likely to have been freedom of intercourse between the adjoining houses, the Plague Officer had power to disinfect this house also; but it was not a rule.

21,699. Were those measures adopted at any particular stage in the second epidemic, or throughout the epidemic?—We depended more on gaining the confidence of the people, and we elaborated the volunteer system more, and formed Chief Volunteers. Colonel Creagh and myself were appointed to the then existing Committee, and I think the principal change was the appointment of Chief Volunteers, who went round in a spirit of conciliation; and more power was given to them, and now they are appointed the Chief Executive Officers of the Pet.

21,700. Were the measures adopted in their full development at the commencement of the second epidemic, or were they elaborated during the course of that epidemic?—We changed the measures to this extent, with regard to the searching more particularly; before, the searching was done by one centralised party, and then the other system came into force—what one might call the decentralised system—by which the Superintendent was appointed the plague official for each Pet, and he was the responsible officer for that Pet.

21,701. What was the effect of all this modification?—These measures came into force about a week before the fall, the 27th November is put down as the date of the revised measures, and from the 11th of December there was a continuous fall.

21,702. What essential difference had existed in the treatment of your plague measures anterior to the fall, as contrasted with the measures which took place at the time of it or subsequent to the fall?—I think the most important one was undoubtedly one of organisation, a decentralisation by which each Plague Officer was made responsible, and he had his own equipment complete. He was the Plague Officer of the division to whom all the inhabitants of that particular Pet could apply. There was a plague office established in each of the plague divisions.

21,703. Putting aside the fall in the mortality, what do you think was the valuable result of this change of organisation that you speak of?—I think it gave more confidence to the people.

21,704. In what way?—That they had someone to apply to.

21,705. Did it result in your getting better information as to the cases?—Undoubtedly.

21,706. You got better and more reliable information?—Certainly.

21,707. Your information before was not so good, and, therefore, you could not carry out segregation so thoroughly?—I think one would argue that was so.

* "Report on the Poona Plague Operations," by the late Mr. W. C. Rand, I.C.S., Chairman, Poona Plague Committee, printed on pp. 301 to 357, Vol. II., of "The Plague in India, 1896-97," by R. Nathan, I.C.S.

21,708. The more perfect your means of obtaining early information, the more perfect were your measures?—Undoubtedly.

21,709. The plague continued to increase until this improvement of measures had been attained, I believe?—Yes.

21,710. And then it fell rapidly?—Yes.

21,711. What are your views with regard to evacuation?—I think, from the experience I have gained of evacuation, that it is a most valuable measure. On the other hand, I am not at all sure whether a lesser alternative might not be as efficient. If we get early information of cases I am inclined to think, from our experience here, that one can limit the zone of infection; that being so, evacuation would be unnecessary.

21,712. With that condition, that you have a limited zone of which you have information?—When I said a limited zone, I meant more particularly that each particular case could be limited to the house in which it occurred. In our experience here up to now, January 1899, we have been able to limit the spread in this way, and even if several cases arise, these can in a large town be prevented from spreading by prompt action. Of course I am speaking now of one's experience of limiting plague in a big city, which experience is naturally extremely small.

21,713. Your experience has hitherto been of cases where you have had early information of isolated cases, not more than one or two in number; in that circumstance what action do you consider sufficient?—We have been able to limit the plague to the particular spot in which we get information of it, by the patient going to hospital, or if a corpse was found, the corpse being removed, and the people in the house being placed under surveillance, disinfection of the house, and disinfection of the clothes of the people who inhabited the house being carried out.

21,714. If the area affected be a larger area, you may require to modify those measures, may not you?—Just now one might say that this system is on its trial. This particular outbreak we have now is more or less confined to a block of buildings about 100 yards square, and I was inclined to think that it was due to some infective agency that we had not before in Poona, rats or something like that; but I still think that our operations will be effective to treat this block in the same way as we treated the cases before, and without evacuation.

21,715. Not paying any attention to the immediately contiguous houses?—No; unless we have evidence that there has been some direct contact. A house leading into another house, perhaps without any wall, and where neighbours are known to have had intercourse with each other, would be disinfected.

21,716. You would treat contacts in the same way as actual patients?—We would treat that house in the same way as we treated the other house.

21,717. Why do you think removal from the house to a health camp, or isolated place, stops the extension of the plague?—You get away from the infected floor, and you disinfect the infected clothes. I think both the floor, and particularly the clothes, are very infective—as far as I know they are the only factors, with the exception of pneumonic sputa, that have proved to be infective.

21,718. Is there any other factor which may explain the good results of removing people into a health camp?—They are placed under better hygienic conditions.

21,719. What evidence is there, to your knowledge, that that is an operative condition?—It is a presumption that if you take people from ill-ventilated houses, and place them in good airy houses, that the hygienic conditions are better, and one can say that under better hygienic conditions the general health will improve.

21,720. As a general principle?—Yes.

21,721. Have you any experience with regard to segregation camps which would lend weight to your supposition? In these segregation camps was the general hygienic condition the same as in the localities from which the inmates had been removed?—No, much better.

21,722. You have stated that you consider that infection is due to the infection from floors and clothes, and from pneumonic sputa. What influence do you consider rats or other animals to have upon the spread of plague?—I have had no direct experience of the spread of plague by rats, although from what one reads one is inclined to think there must be something in it.

21,723. Do you know if any large number of rats did die here during any of the epidemics you have been concerned with?—No, we have never had a large mortality in rats.

21,724. There was no warning given in any house where plague occurred by the death of rats, of the possibility of plague occurring in the house?—No; we have received reports of rats having died, but I do not know that I can remember having seen a dead rat in Poona. I certainly have not seen any in this last outbreak.

21,725. Why do you think that the condition of floors is a great means of propagation of plague? On what data do you make that assertion?—Because if you move people from those floors they do not get the plague.

21,726. Have you ever removed them without also disinfecting?—Their clothes were disinfected on arrival in camp. I have said in my précis of evidence: "In "the infection caused by floors I also include infected "clothing."

21,727. How do you think floors would retain the plague virus and thus become a special means of propagating plague?—I think that any floor that contains material for the propagation of germs will retain them longer, and be a more favourable bed for their spread.

21,728. What kind of floors were they?—Mud floors.

21,729. Such as would be favourable for the retention of organic matter?—Yes.

21,730. Would that extend to stone, or wooden, or concrete floors?—That I have very little experience of. There are practically no floors of that sort in Poona.

21,731. You wish to speak of mud floors, which contain greater organic matter?—Yes.

21,732. I think that, generally speaking, you are of opinion that pneumonic cases can be detected by medical examination?—Yes.

21,733. Will you tell us how you detect such cases?—One arrives at it by a process of exclusion mostly. There is a history of cough, and there is sometimes a very frothy condition round the mouth of the corpse—a congestion round the mouth and nostrils.

21,734. Supposing you found a person who was ill, how would you form the diagnosis of pneumonic plague? On what grounds would you arrive at a conclusion, before death?—One would naturally go by a bacteriological test, had one facilities for doing so.

21,735. I ask you, because you have made the statement that a pneumonic case would be detected by medical examination before it develops into the contagious stage?—That is, during life in a health camp.

21,736. Assume it is in a health camp?—Because these people in the health camp who are under medical observation would, on the first sign of fever, be put into an observation ward before they develop into the pneumonic stage of plague.

21,737. You mean, then, not so much the discovery of the pneumonic plague as the prevention of harm from any possible pneumonic cases?—Quite so.

21,738. You had no certain means of detecting pneumonic plague, had you?—No. I mean they would be detected before they developed into the pneumonic condition.

21,739. Have you any experience with regard to inoculation as a plague measure?—No. I have been in villages in the district with Professor Haffkine to assist him, but I have had no experience.

21,740. Have you formed any opinion as to its value as a plague measure?—I think it may be of value in segregated communities, such as people in jail, and in regiments. Universal inoculation seems to me to be a difficult thing to carry out.

21,741. Assuming that it is really preventive, you mean that it is limited in its applicability?—Yes.

21,742. Have you had any experience of the reinfection of any houses which have been disinfected?—No, none at all.

21,743. Have you had any experience of cases which suggest recrudescence of the disease, that is to say, apart from a fresh importation?—No.

Major W. L. Reade, R.A.M.C.

24 Feb. 1899.

21,744. You do not believe in recrudescence in the soil?—I must say I do not now. I was quite prepared to believe in it, but with the experience that one has now had, I do not think that belief was justified. I can only argue from an extremely limited amount of experience from a plague point of view, but, judging more particularly from Poona, a city which has been badly infected for two years, if there is such a thing as recrudescence in the soil, I think one would have had an outbreak before now.

21,745. In the meantime, experience shows you that plague does not occur without any direct infection from either clothing or persons?—Undoubtedly, it does not occur without direct infection.

21,746. With regard to disinfection could you describe what disinfectants you have employed here?—We have employed always the perchloride of mercury solution, 1 in 1,000, which we have recently strengthened to 1 in 725, with hydrochloric acid.

21,747. An acid solution of perchloride of mercury?—An acid solution, yes.

21,748. How do you apply it?—It is syringed on to the floor and walls of an infected house through the medium of wooden syringes. This is very freely done.

21,749. Is the syringing done on one or more occasions in any given house, or do you repeat it before the house is re-occupied?—Only once.

21,750. Do you think it necessary to include in disinfection the ceiling and every part of a chamber, or do you limit yourself to the floor and to a part of the wall?—As a matter of fact, when we are about it, we do the whole room, but I should be inclined to say that the floor and a very few feet of the walls was sufficient. At the same time, I think, from our present knowledge of plague that it would be a rather dangerous experiment to limit it to this. When one is about it, it is very easy to squirt everywhere.

21,751. Did you disinfect the articles in the chamber with the same chemical disinfectant?—That was always done by a steam-boiler—when the people were brought to the segregation camp. This was done away with in the segregation camp, and latterly we have been employing the railway disinfector—sending the people's clothing there.

21,752. Have you any distinct case in which clothing itself, apart from a living being, has communicated plague to a person?—The best example in my experience was the Karachi health camps in 1897. They had enormous health camps there. I think at one time there were something like 20,000 people in camp, and plague at that time in those camps was as bad as it was in some of the worst infected parts of a big town; in fact in one of the Karachi reports it was stated that there was hardly a hut that had not a case in it. After the disinfection of clothing was carried out, they came under the ordinary conditions of a health camp, that is to say cases did not develop in the camp after the incubation stage had elapsed.

21,753. The conditions in all other respects were the same?—Exactly the same.

21,754. How do you think the virus gets admission into the body?—I think it must be by inoculation.

21,755. That is so far as the skin surface is concerned?—I think, possibly, the tonsils may get inoculated also.

21,756. You think it may be introduced through a mucous surface as well as the skin surface?—Yes.

21,757. How do you think the virus penetrates to the skin surface; how does it reach the blood ultimately?—I could not give you an opinion on that. I have not been able to trace any local seat of inflammation, in the majority of cases.

21,758. Any lesion, or what?—Cracks or cuts in the feet of the natives. They are generally cracked, but I have rarely been able to trace any lesion or point of inoculation.

21,759. Have you any opinion as to whether the virus can pass through the unbroken skin or not?—Only purely negative ones—that one looks for these abrasions and one cannot find them.

21,760. You also think that it is absorbed by the tonsils?—I think it is physiologically probable.

21,761. Have you any case to justify that statement?—The infection of the cervical glands would possibly show infection through the mucous membrane of the tonsil.

21,762. The jaw glands, the parotid, and so on?—Yes.

21,763. Have you seen cases of that sort?—Yes, a great many.

21,764. Have you any evidence to show that it may be absorbed through the alimentary canal?—No

21,765. You have seen no such cases?—I may say I have not done much hospital work; my experience has been chiefly administrative.

21,766. Would you give us some account of what you consider a sufficient organisation for stamping out plague in a town?—We have in Poona a system of 12 or 13 Chief Volunteers, and we have had a surveillance system, and we have been able to treat each case of plague as it arises. Now that we have infection in a large block, we have had to increase our disinfecting parties. We had 10 soldiers employed as disinfectors, and six coolies from the Municipal authorities, for each party, and we formed 10 disinfecting parties, each party under a soldier. In that way one can work with a skeleton organisation, which can be readily increased if the disease was progressing.

21,767. What do you trust to in order to prevent the introduction of plague into a town, and to discover it when it has been introduced?—The first line of defence is by the rail—inspection at the railway station. An inspection of all passengers who arrive at Poona takes place there. Of course there are some who get out at some of the wayside stations and come in by road.

21,768. What is done with them if they are detected at the railway station?—If there is a rise of temperature they are sent to hospital.

21,769. For how long are they detained?—Until definite plague symptoms have developed. At the railway station the people who arrive in the town are placed under surveillance, which is done in this way, a certain number of volunteers, native gentlemen, vouch for people they know, respectable inhabitants of the town. A certain number of the arrivals have what we call "ward passes," which are passes given by the Superintendents of the divisions stating that the person is known, and resides in a certain house, and is going away for three or four days; and when he comes back again he produces this pass. He is then allowed out. There are a certain number of people who can give no fixed address, people coming to the city to work, and so on, and they deposit their baggage and bundles in a camp close by the station; these bundles are entered in a register, and then the people are allowed to go into the town. They are given the address of the Chief Volunteer of the division in which they are going to live, and as soon as they have intimated to him the house they wish to live in, they get a release ticket, and this is presented to the officer in charge of the railway camp, they are then released and placed under ten days' surveillance in the ward office of the Pet they are going to live in.

21,770. They have to report themselves?—Yes, every alternate day.

21,771. That is in order to get as early information of plague as possible, I suppose?—Yes.

21,772. Have you any other means of getting early information of plague?—Then we have sick certification, people have to report, or are supposed to report, all illnesses, and reports are recorded on a list.

21,773. When they report any sickness, what step is taken?—The medical officer on duty proceeds to the house to diagnose the case.

21,774. Are there any other steps that you take for getting early information regarding plague?—Finally, we have the system of corpse inspection. We have the volunteers, in conjunction with the census clerks, who keep up the census of the houses.

21,775. Is that census checked now?—Yes.

21,776. At what intervals?—Once a week.

21,777. What do you mean by corpse inspection; what does it cover?—It is really a death registration.

21,778. Every dead body is examined?—No dead body can be moved from a house until a certificate has been given by an inspecting medical officer.

21,779. All these measures are intended to give you early information?—Yes.

21,780. You consider that the most important information of all that you can obtain, I suppose?—Certainly.

21,781. And those measures which you have adopted, you have already told us, have been so far successful in preventing indigenous plague?—Yes.

21,782. (*Mr. Hewett.*) What population had you to deal with at Poona during the second epidemic?—From 60,000 to 80,000. I remember going into this question with Mr. Plunkett. He put it at 80,000. We thought it was less, but he, probably, had better information. That was his estimate at the time.

21,783. What is the population at the present moment?—It was taken about a month ago, and it was 130,000.

21,784. That is a good deal above the normal?—Yes, it is 12,000 above the normal.

21,785. Has the mortality been above the normal during the last three months?—Yes.

21,786. Higher than you would expect from the increase of population?—Yes.

21,787. How do you account for that?—We have an influenzal epidemic and also measles, and whooping cough, which cause a large mortality, particularly amongst infant life, and there is no doubt that the influenzal influence is causing mortality among aged people.

21,788. Dr. Venis put before us yesterday a statement of the system of corpse inspection up to the 31st December last. (*See* Question No. 21,416.) Have you got it for a later date?—Yes. (The following statements for the whole of January 1899 were supplied by the Witness subsequently:—

Corpse Inspection, January 1899.

XVII.—Brain diseases	3
XVIII.—Ill-defined causes (including jaundice, abscess, &c.)	14
XIX.—Malignant disease (cancer)	2
XX.—Broncho-pneumonia	40
XXI.—Bronchitis	78
XXII.—Lobar pneumonia	15
XXIII.—Diphtheria	1
XXIV.—Kidney disease	5
Grand Total	385

Mortality for the Month of January.

1896	259
1897	250
1898	497
1899	385

N.B.—In the years previous to 1899, the still births are not included.)

21,789. Can you tell us how many deaths there were during January?—385.

21,790. How many of those were put down to influenza?—There are 40 bronchial pneumonia and 78 bronchitis; and there are 15 lobar pneumonia—all influences of the influenzal prevalence.

21,791. Were there any cases in which the cause of death was not determined during the month of January?—They are all under certain headings.

21,792. There is a heading "Unknown" in the list by Dr. Venis. Was there any similar heading in January?—They are "Ill-defined causes, 14."

21,793. That is a new heading?—Yes.

21,794. You have not got this item "Unknown" in January?—No; they are "Ill-defined causes."

21,795. Was there plague in the villages in the neighbourhood of Poona at this time?—Yes, in January.

21,796. I understood you to say that you did not believe in a local recrudescence?—I have had no experience of it, and I am inclined not to believe in it.

21,797. You made a reference in your précis of evidence to the second outbreak at Karachi having been possibly due to local recrudescence. Do you withdraw that now?—I must say from my experience now, that, if we were going to have a recrudescence here, we would have had it by this time.

21,798. Do you find that the cases which have occurred in the last few days in Poona have occurred either in the houses which were previously infected, or in the neighbourhood of houses which were infected in the previous epidemic?—This I have not ascertained.

21,799. Do you consider that the system which you have now of surveillance of passengers by rail and road is the maximum of interference which can be legitimately taken with the movements of the people? Is it effective in preventing people whom you wish to control from getting into the town without observation?—Up to now I can say it has been efficient.

21,800. You would not advocate any further restriction with the movements of the people?—No, I should not.

21,801. You have not had a general evacuation of Poona?—No, only in isolated blocks.

21,802. Do you think that it would be feasible as a compulsory measure to have a general evacuation of a town of the size of Poona?—Anything, of course, is possible.

21,803. I mean with an efficient control over the inhabitants of the place?—It is entirely a matter

Major W. L. Reade, R.A.M.C.

24 Feb. 1899.

of money. A town can be moved if the money is forthcoming.

21,804. Would you not require an enormous force to control the evacuated inhabitants?—I should think it would be practically impossible.

21,805. If you attempt to completely evacuate a large town, would the probable result be that you would scatter plague cases all over the country?—I think it is very likely.

21,806. When you have plague in a village, do you think there is the same objection to evacuate the whole of it as there is in the case of a large town?—No, I do not.

21,807. Are the villagers accustomed to camp out in their fields?—Yes.

21,808. Do you think that the villagers of an agricultural village are likely to go moving about the country because they were camped out owing to plague?—I do not think so. I think the agriculturists will still stay by their villages.

21,809. The majority of villagers who are agriculturists are wrapped up in their village site, and having no business elsewhere, would not be likely to go away?—Yes; but that is not applicable to all villages.

21,810. You have villages in which the population are more like the population in a town in this respect, —that they are more accustomed to moving about over a larger area?—Yes.

21,811. Do you think that voluntary evacuation in such villages as those is likely to lead to plague spreading about from place to place?—I think so, undoubtedly.

21,812. Would you ever allow home segregation—in Poona, for instance?—It has never been allowed.

21,813. Would you allow it?—I should be sorry to say what I would not be prepared to allow in plague. One gets new ideas every week in plague.

21,814. Do you think that it would be impossible to allow a patient to remain in his own house, provided that is suitable, and that he can be isolated, and properly attended in it?—This is supposition. I think it is possible that it might be done. I am only presuming that certain conditions were followed.

21,815. Would you please specify the conditions?—The strictest disinfection of floors. You would have to evacuate the house while the disinfection was going on. In double-storeyed houses, I should be very sorry to say one way or the other.

21,816. You have formed no definite opinion against house segregation under such conditions?—I have not.

21,817. What arrangements do you now make as regards segregation of the other inhabitants of a house when you take a patient to hospital?—They are sent to the segregation camp; it is really a surveillance camp; it is not close segregation.

21,818. How long are they kept there?—10 days.

21,819. During those 10 days are they permitted to re-visit the house in which a case of plague has occurred?—The house is immediately disinfected and thrown open. As soon as it is dry it can be re-occupied.

21,820. They may be there during the day, but not during the night?—That is so. They sleep in the camp for the first four days.

21,821. Do you disinfect all the houses in the neighbourhood of a house in which plague now occurs?—No.

21,822. You do not consider that to be necessary?—I may say, with regard to this recent outbreak, that I was under the impression that it might be due to some rat agency. I do not think so now, in fact, I am sure that it is not. I thought that there might have been some universal floor-infection by rats. We commenced a modified sort of evacuation; but now each house is being treated in the ordinary way. In the case of a death from plague the house is evacuated and disinfected.

21,823. Does the system now in force in Poona, as regards the treatment of the patient, the treatment of the other inmates of the house, and the disinfection of the house, represent your mature experience as to the best way of dealing with a large outbreak in a town?—Yes.

21,824. Do you find any objection on the part of the people here to corpse inspection?—No, none.

21,825. If you have any specific instance, perhaps you will tell us?—The only specific instance brought to my notice was with regard to the inspection of the corpse of a fakir. It was brought to our notice by one of the Chief Volunteers of a Pet who said that the man was of holy habits and an ascetic, and that the people did not wish his corpse to be handled by an European doctor. We assented, and said that they might have a Brahman doctor, the European doctor being present. There was no difficulty about it. There was also one objection from a Muhammadan, but that was easily got over. The corpse was allowed to be inspected.

21,826. Have you any system of pardah among the Hindus here?—No, none to my knowledge—not in Poona city.

21,827. Is there a Muhammadan population among whom the pardah system prevails largely?—I should say not.

21,828. Is it an influential one compared with the Hindu population, and compared with the Muhammadan population of other places?—The Muhammadan population is about 15,000.

21,829. That is, relatively, very small, is it not?—Relatively small to the other inhabitants.

21,830. Is the Muhammadan population, as compared with the Muhammadans in other places, a highly important population?—There is a large community of Borahs, numbering about 1,000. I should not say that there is the same number of educated people amongst the Muhammadan population here as there are amongst the Hindus, in fact, I am sure there is not.

21,831. Would you consider that the Muhammadans have the same influence and importance in the city of Poona as they have in some of the more important cities of the Punjab and North-Western Provinces?—I have no data upon which I can give an opinion.

21,832. A statement appears in the first few lines of your précis with regard to the number of cases of plague which occurred in the health camp during the second epidemic?—Some 4,800 persons were sent to the health camp at Bhamburda from infected parts of the city. I say in my précis that out of this number only three cases of plague occurred. I ought to have said that out of this number only one case of plague occurred. I have that from the records of the General Plague Hospital.

21,833. Have you any figures as regards railway and segregation camps since the late Mr. Rand's report* ?—There is the report on the railway detention camp by the Superintendent who was there.

21,834. Could you give us similar figures to show how many persons went into the railway detention camp, and how many cases of plague developed there?—The total number of contacts segregated in Sawar's Gate Camp was 13,213, and there were 146 cases of plague. In the Station Camp there were 13,670 persons detained and 23 cases of plague occurred. Nine deaths, not from plague, occurred in camp.

(The following facts appear from the report of the superintendent of the railway detention camp referred to in the previous question, which is not reprinted with the Proceedings of the Commission. The camp, to which the report relates, was opened on the 13th of February 1898, and the report gives figures regarding it up to the 20th May 1898, when only 47 inmates remained. These figures are as follows:—

For the Week ending Friday	No. of Persons detained.	No. of Persons discharged.	Balance.	No. of Cases of Plague detected in the Camp.

* Printed on pp. 301 to 357, Vol. II. of "The Plague in India, 1896–97," by R. Nathan, I.C.S.

Of the 23 cases of plague, 2 were discovered on the 5th day after the patients entered the camp, 1 each on the 6th and 8th day, and 2 on the 9th day. It is probable that most of these patients were ill before their sickness was discovered. Of the *détenus* 8,450 came from Bombay, and 5,220 from other places; they were grouped in the camp by castes, but there was no special grouping of persons according to the place they came from; and though cases from elsewhere were taken out of the trains, only persons from Bombay became sick of plague while in the camp. It is therefore probable that the persons who developed plague after a stay in camp of 5 days or more, did not acquire their infection in the camp.)

21,835. Can you give us any information which would bear upon the period of incubation? Can you tell us, day by day, how many cases developed, and, if there was a prolonged period of incubation in any case, state whether it was due to re-contact or not?—The following statement shows the period of incubation:—

Plague occurred within	24 hours	in	21	cases.		
,,	,,	after	1 day	,,	20	,,
,,	,,	,,	2 days	,,	17	,,
,,	,,	,,	3	,,	22	,,
,,	,,	,,	4	,,	22	,,

The last two cases were due to the patients being kept under observation for a few days before a definite diagnosis of plague was arrived at.

21,836. Have you had any instance where plague has moved to a house adjoining an infected house without any means of communication between them, and without any apparent communication between the residents of the two houses?—I cannot say that, unless one could eliminate all human means of intercourse. I have never been able to do that.

21,837. Although you have an open mind as regards the communication by rats, you do not think that other animals communicate the disease?—I cannot answer that.

21,838. Do you know whether there was any Health Officer here when plague broke out in the first epidemic?—Yes.

21,839. Do you know what qualifications he had?—He was a Parsee gentleman, an L.R.C.P., of Edinburgh.

21,840. Is there a Health Officer now?—Yes.

21,841. Who is he?—Dr. Dantes, a Goanese.

21,842. Do you know anything of the ordinary powers of the Health Officer?—The powers of the Health Officer have practically been absorbed by the Plague Committee.

21,843. Have you as the Executive Officer in charge of plague operations here rather larger powers than the Health Officer?—Very much larger.

21,844. Do you think that it is necessary under ordinary circumstances that the Health Officer should have as large powers as you have now?—No, I do not.

21,845. Do you think that it is necessary in ordinary times that the Health Officer should have more enlarged powers than he already has?—Yes. I think the Health Officer would find it rather hard to define his own powers here.

21,846. Would it not be desirable that his powers should be strictly defined?—I think so.

21,847. Do you know whether there was any byelaw as to the registration of deaths in Poona at the time when plague originally broke out?—I could not say.

21,848. Do you think that in a Municipality such as Poona there should be a byelaw requiring the registration of deaths under ordinary circumstances?—Undoubtedly.

21,849. Do you think that there would be any difficulty in rigidly enforcing such a byelaw, provided that the Health Officer's authority was properly maintained?—I do not think that there would be.

21,850. Do you think that it would be easy to enforce such a byelaw provided the Health Officer had no more authority than he had under ordinary circumstances—than he had at present?—I think it might be enforced.

21,851. Is it your opinion that there is any measure which is more urgently required in connection with the suppression of the plague than some system for securing the accurate and early notification of cases of death of all kinds in the larger cities?—Early notification is the most important measure to enforce from a plague point of view.

21,852. Have you had any experience in rural areas?—I have been in charge of this district for the last seven months.

21,853. Do you regard it as desirable to endeavour to secure early and accurate notification in rural areas as well?—I think it is, but less important than in towns.

21,854. Do you think it would be very difficult to secure such notification in rural areas under ordinary conditions, at all events during the next few years?—As a routine system I think it would be extremely hard to get a reliable return.

21,855. Do you think that it would be possible in a large Municipality like Poona to have a byelaw which would require that cases of epidemic disease should be reported under ordinary circumstances?—I think it is a most advisable law; but it would be impossible to carry it out in India. You mean the same notifications of contagious diseases as in England?

21,856. Quite so. First of all notification of sickness, then notification of death. You agree that notification of death could be insisted on. I want to know whether you think that a similar byelaw requiring notification of epidemic sickness could be carried out?—It is not possible here, not in the present state of things, where 90 per cent. of the people die without being seen by a doctor.

21,857. (*Mr. Cumine.*) Do you consider that the measures in the second epidemic were materially different from the measures in the first epidemic?—Yes.

21,858. It seems that the first epidemic lasted from five to six months, and had a climax of 453 attacks; and that the second epidemic lasted six or seven months, and had a climax of 420 attacks. Can you point to any material difference between the course of the two epidemics? Can you tell us to what extent the modification of the measures in the second epidemic made the second epidemic run a different course from the first epidemic, made it cease sooner, or made it produce fewer attacks? I want to see to what extent the difference in measures produced a difference in the course of the epidemic. You say the measures differed materially in the second epidemic from those in the first. Did the course of the second epidemic differ from the course of the first? Did the change of the measures in the second epidemic produce a difference in the course of the epidemic?—I cannot say. I do not think I have compared the charts.

21,859. Dr. Venis gave a table of statistics on corpse inspection. Does the number in his table mean the number of corpses that were inspected, or does it mean the number of corpses the inspection of which revealed the cause of death—the number of cases in which the cause of death was not known until the actual inspection of the dead bodies? Which does it mean?—His table shows cases that have been inspected by a medical officer during his corpse inspection of the city.

21,860. It merely means the number of dead bodies that have been looked at?—Quite so.

21,861. It does not mean the number of dead bodies whose cause of death has been ascertained purely and solely by looking at the corpse itself?—It means every case that died out of hospital.

21,862. Would it be possible to tell us to what extent in the case of the corpses in this table the cause of death was ascertained by the inspection of the corpse

Major W. L. Reade, R.A.M.C.

24 Feb. 1899.

and the inspection of the corpse alone, without having seen the patient before death, and without having had any history of the patient's illness? For instance, I find heart disease put down there. Could you tell, by inspecting the body of a person who died from heart disease, that heart disease was the cause of death?—No, certainly not.

21,863. That would be one case in which corpse inspection would not in any way assist in discovering the cause of death?—That is so.

21,864. Could you tell us whether, amongst these corpses, there are any corpses in which the cause of death (including plague) was discovered by corpse inspection alone?—Yes.

21,865. I want to see what the value of corpse inspection is when you have corpse inspection alone. Supposing you found a body lying on the road with nobody near, and nobody to tell you the history of the case, and you had nothing to look at but the body alone, that would be an instance where corpse inspection was the only thing you had to enable you to find out the cause of death. After eliminating all cases where you had other things to help you, how many cases will remain in this table where you had nothing but the view of the body itself to enable you to tell what the cause of death was?—We know that 85 per cent. of the cases of plague died of bubonic plague, which is an objective feature in a corpse.

21,866. Are not buboes sometimes absorbed immediately before, or immediately after death?—I have never heard of a case. It is not my experience.

21,867. In the case of a certain number of people who die of plague, it is possible to tell from the circumstances and surroundings that they died of plague, is it not?—Yes.

21,868. For instance, if two people died in this room yesterday, and a third person dies to-day, would not that fact of itself, without examining for buboes, be enough to make you assume that the person died of plague?—One would be extremely suspicious that it was so, there being two cases in one house.

21,869. You have only had two or three objections made to the examination of corpses, but have you had any complaints from people saying that corpses have lain for a very long time in their houses because the medical officer has not come to examine them?—Yes.

21,870. How many such cases, roughly, have you had?—I have certainly had two or three complaints. In the volunteer meetings that have been held that point has come up for discussion. There have undoubtedly been two or three complaints made in that way, but very few written ones.

21,871. There have been undoubtedly complaints of what?—That a delay has occurred.

21,872. (*Prof. Wright.*) You receive information of sickness in the town by reports, do you not?—Yes.

21,873. These reports come to you from doctors practising in the town?—Yes.

21,874. And from volunteers?—Yes.

21,875. And, further, from the relatives of the patient?—Yes.

21,876. Would you tell us what percentage of reports come from the relatives of patients?—I am afraid I do not know that.

21,877. Could you prepare a table and give your sources of information?—There were 2,863 cases reported altogether.

21,878. During what period?—12 months.

21,879. For 12 months, 1898, the number of cases given in the table prepared by Dr. Venis as certificated is 1,891?—Those are by volunteers, doctors, and relatives.

21,880. Was this table prepared under your supervision?—Yes; but I have not looked over the figures recently.

21,881. Am I right in saying that a very few cases were reported by the relatives of the patients?—I should not like to say what the percentage was.

21,882. Have you an impression as to whether few or many were reported by the relatives of the patients?—I should say a great number.

21,883. Out of those 1,891, how many were reported to you by the relatives of the patients, how many by doctors, and how many by your volunteer committee?—(The following figures were supplied later by the witness:—)

There were reported by relatives -	402
" " " doctors - -	54
" " " volunteers -	1,435
	1,891

21,884. What penalty was there for not reporting?—The penalty has varied very considerably. The penalty used to be that the people were put into the segregation camp or under surveillance. Practically, however, we have never, or very rarely, exacted the penalty within the last three months. We wish to diminish all motive for not reporting or concealment of any sort.

21,885. But the exaction of a penalty is a motive for reporting cases, and a remission of the penalty is a motive for concealing cases, is it not?—I suppose it is.

21,886. How many cases of sickness do you think escape detection in Poona in a year?—I do not know.

21,887. How many unreported cases of sickness, do you think, occur in a year in Poona city? I make out that 1,900 cases were reported to you, and of those 600 died. That is a proportion of one case of death to three cases of sickness. With your total of 3,000 deaths, I take it that you would have 9,000 cases of sickness. Am I right in that?—Yes.

21,888. How many cases of plague were detected during life, during 1898, by means of the visitation of the sick? Am I right in saying that there were 25?—Twenty-one by visitation of sick, from May 1898 to January 1899.

21,889. What object was achieved by the detection of these 21 cases in life?—To get the case early—to take early measures. The sooner you get an infected unit the less likely he is to spread infection.

21,890. Were these 21 cases removed to hospital; you did not, did you, bring them all to the hospital?—They were brought to hospital.

21,891. What is the advantage you are going to obtain from your sick inspections in the future? I understand that you are going to leave moribund patients in their houses?—None of the cases detected from May 1898 to January 1899 were moribund.

21,892. A large number of the cases which you will detect by your sick inspection will be moribund cases, and, therefore, you will leave a large majority of the plague patients whom you discover in their houses?—Arguing from our previous experience I should say not. This system has not been tried.

21,893. And you propose to isolate certain other plague patients in their own houses?—No, I am prepared try it.

21,894. Those, also, you propose to leave in their houses?—No.

21,895. And, again, certain of the plague cases which you detect will come under the category of suspicious cases?—Yes.

21,896. Those, also, you will be compelled, will you not, to leave behind in their houses?—We have an Observation Hospital.

21,897. Will you take these merely suspicious cases away from their houses?—It is not an absolute rule about people being treated in their own houses. Each house will be treated on its own merits. We will take into consideration whether it is a suitable house for a patient to be treated in, or not.

21,898. The point that strikes me is this. There are very few cases detected during life and most of these you will be compelled to leave in their quarters for one reason or another. You will leave them behind, either because the diagnosis is not certain, or because the house is good enough to permit of the treatment of the sick in it, or, lastly, you will have to leave your plague patients in their houses because they are already moribund when you find them. In view of these facts I want to learn what advantage will accrue from your system of sick visitation?—Up to date no trial has been made of treating patients in their own houses, and out of 25 cases which occurred during 1898, 23 were seen during life and all were sent to hospital. One advantage will be that in a large town we hope to diminish panic.

21,899. How can you diminish panic by going to see sick persons in their houses?—By allowing certain cases to be treated in their houses.

21,900. I am not doubting the wisdom of your plague policy; I want merely to learn how you are advantaged by finding a plague patient while he is alive, if you have, from one cause or another, to leave that plague patient in his own house?—By antiseptic precautions the conditions existing in hospital might be approximated.

21,901. (*Mr. Hewett.*) In these cases in which plague was detected during lifetime, would it not be an advantage that you would also find the contacts?—Yes, undoubtedly.

21,902. (*Prof. Wright.*) I will now go to corpse inspection. You have a table here (*see* Questions No. 21,416 and 21,788) in which deaths are classified according to causes; is there any one of these diseases, with the exception of plague, which is enumerated in that table, which can be detected by mere inspection of the corpse?—As vital statistics, I do not think the table is worth anything. Cholera, small pox, and leprosy, are diseases which could be diagnosed after death.

21,903. Why are the cases not classified simply under the headings of "plague" and "not plague"?—It is the nearest approach that one can get to some sort of registration. We tried to get it in that way—we were only concerned with plague. There was no particular reason why we adopted this course. At first we commenced with "plague" and "not plague."

21,904. On what principle is a person put down as dying from asthma or bronchial pneumonia?—I admit that the table is of no value from a vital statistical point of view; it is the best approximation to accuracy.

21,905. What is the best you can arrive at in the matter of a determination of the cause of death? Can you arrive at anything more than a classification of deaths into a class of "certainly plague," "certainly not plague," and "suspicious"; is not that the most important classification which can be based upon corpse inspection?—Practically that is all, except cholera, small pox, and leprosy.

21,906. With regard to these cases, when you classify a case as "due to plague," I presume that this will happen only when a corpse is found to have buboes?—Yes.

21,907. Further, I presume, that if a corpse has no buboes, you put that down as "suspicious," whenever you find that another death has occurred in the same house?—Yes.

21,908. And if you find a case of sudden death, you put that down also as "suspicious"?—Yes.

21,909. If you find that a body is well-nourished and that the period of illness has been very short, you also put down that case as "suspicious"?—Yes.

21,910. And if, further, you see that the tongue is furred like a plague tongue, and if you see that the conjunctivæ are injected, you would put that down as "suspicious"?—Yes.

21,911. So that you would have quite a large number of cases which you would classify as "suspicious"?—Yes.

21,912. With regard to disinfection, you would disinfect, would you not, all the houses where deaths had occurred which were certainly due to plague?—Yes.

21,913. What would you do with houses in which suspicious deaths had occurred, would you disinfect these houses also?—We have done so up to now.

21,914. I find that in certain months, for instance, in November and December last, no plague cases were detected in Poona: that means, I presume, that no corpses with buboes were detected? But there may have been suspicious cases, may there not, in those months?—Yes.

21,915. Was disinfection carried on all through November and December, or was disinfection suspended?—Instructions were given to the Inspecting Medical Officer that in all suspicious cases the certificates were to be marked "suspicious," and they were treated as plague cases. With regard to the measures taken, the place was disinfected and the people were placed under surveillance.

21,916. Did suspicious cases occur right throughout or was there any month in which no suspicious cases occurred?—We have been getting a large number of cases the last few months.

21,917. Was there any month in which you had not suspicious cases, any month in which you can assert that there was no plague in Poona?—I could not say.

21,918. We have, for instance, a great number of cases of bronchial pneumonia and bronchitis set down for the months of November and December, and I understand that there were such deaths in January?—Yes.

21,919. Were all these suspicious cases from your point of view?—Yes.

21,920. Was disinfection carried out in all those cases?—In every case marked.

21,921. In view of the fact that a large number of cases can only be classified as "suspicious," and in view of the fact that you cannot in these cases arrive at a definite opinion as to whether you are or are not dealing with plague, do you not think that corpse inspection, as at present carried out, is unsatisfactory?—No, I do not think it is.

21,922. I presume you can never, by your present methods, certify the town to be free from plague?—I think you may arrive at it by bacteriological examination.

21,923. Do you think that corpse inspection ought to be supplemented by bacteriological examination of the the suspicious corpses?—Yes.

21,924. Have you any means of supplementing your corpse inspection by bacteriological examination?—No, not in Poona.

21,925. Have you represented the great importance of such a bacteriological examination of all the suspicious cases?—We sent down to Bombay to have some examined.

21,926. Do you know how many specimens derived from corpses were sent down to Bombay?—Seven altogether.

21,927. Do you not think that there would be a great advantage in having the bacteriological examinations done here?—Yes.

21,928. And, further, that it would be a great advantage to have these bacteriological examinations made in all suspicious cases?—Yes.

21,929. Do you think that corpse inspection, combined with the bacteriological examination of suspicious cases, would be the most valuable agency that could be employed in detecting plague?—Yes. I think it would diminish the necessity for our measures of disinfection which we have to take now.

21,930. I understand you have to waste a lot of disinfectant now simply because you do not know whether suspicious cases are really cases of plague or not?—We disinfect the houses almost immediately, and we put the inmates under surveillance. Directly the diagnosis is cleared up, and we know that the case is not one of plague, they are no longer put under surveillance.

21,931. You think that you might stop disinfecting operations altogether as soon as bacteriological examination showed that no more cases of plague were occurring in the town?—Undoubtedly.

21,932. (*Mr. Cumine.*) With regard to the present infection of Poona, was not the mischief done before you ever saw the corpse at all? Was not Poona infected before the man died?—Yes.

21,933. In this case the damage was done before the man was a corpse?—I have admitted that you could not repair that particular damage by the system we have now.

21,934. (*Prof. Wright.*) But the fact that this case of plague was detected immediately after the man died is evidence, is it not, of the utility of your system of corpse inspection?—Yes.

21,935. (*The President.*) What is the largest number of people you have evacuated in Poona at one time?—We evacuated 4,800 people into the health camp at Bhamburda.

21,936. What is the largest number of people you have had evacuated in one given time?—962 was the maximum.

21,937. I do not understand your views about home segregation. I thought you said that it was attended

Major W. L. Reade, R.A.M.C.
24 Feb. 1899.

with very considerable risk?—We have never tried home segregation. I said one did not know what minimum one might eventually come to with regard to segregation. It is a system of which I have had no experience. One is prepared with plague, however, to have an open mind with regard to any particular measure.

21,938. You think there are so many risks that the experiment would be unadvisable unless you had some further experience?—Quite so.

21,939. Do I understand that your plague cases are not being treated at home at the present moment?—Home treatment is on its trial.

21,940. What are you doing?—The regulation passed recently on the subject was to the effect that cases which were reported early, and were found to be in airy houses, would be allowed to be treated in their own homes.

21,941. Are there not the same risks, or nearly the same risks, in that measure as there would be in home segregation?—There is risk to the attendant or relative, undoubtedly. One tries to diminish that by putting disinfectants freely on the floors.

21,942. Is there a risk of outside conveyance by friends?—There is a possibility of it, but from one's experience in Plague Hospitals I do not think it is very great.

21,943. I do not refer to Plague Hospitals; I refer to houses in the centre of the town where a plague patient is being treated. Are there not great risks of infection being conveyed outside that house, which you cannot keep under control in the same manner as a Plague Hospital, where friends come in and friends go out? Have you had much experience of this treatment?—It is on its trial. That is the regulation now in force, and we are waiting results.

21,944. With reference to the registration of deaths, I think you said you considered that that was a very important measure, and should be carried out effectively; that you should have an improved system of registration of deaths so as to obtain early information of the cause of death. Is that not so?—Undoubtedly.

21,945. You said that that was the greatest requirement at the present time?—Undoubtedly.

21,946. With regard to what?—Plague, and epidemic diseases generally.

21,947. What do you say now with regard to sanitary measures? How far would your opinion be modified if you also took into consideration sanitary measures and their influence in reducing the likelihood of epidemic diseases?—I think they have much greater influence in some diseases than in others.

21,948. With regard to generally prevalent diseases, sanitation takes an important place?—With regard to plague, and such diseases, I think it has a very vast influence; but with regard to small-pox, and so on, I do not think it has the same influence.

(Witness withdrew.)

Capt. C. K Morgan, R.A.M.C.

Captain C. K. Morgan, R.A.M.C., called and examined.

21,949. (*The President.*) You are in the Royal Army Medical Corps?—Yes.

21,950. (*Prof. Wright.*) How long have you been on plague duty?—About two years.

21,951. Have you any information with regard to the occurrence of neuralgia in people who are engaged in plague work, and in Medical Officers who are attending on plague patients?—Yes; in Poona, about the middle of the epidemic of 1897–98 my attention was first drawn, I think by Colonel Fawcett, to neuralgic pains in the glandular regions occurring in those doing plague duty. I inquired of the other officers, and also of the soldiers, and the majority of them admitted that they suffered from the same symptoms. They had neuralgic pains in the glandular regions of the body, in the arm, groin, and in the neck.

21,952. Have you seen any cases in which these neuralgic pains were severe?—Yes, they were very severe in several cases. I am not quite certain, but I think two or three cases went to hospital complaining of the pain.

21,953. Do people who have been a long time on plague work cease to suffer from these pains?—They do not. I have been for two years amongst the plague, and I still have them.

21,954. If you cease to do plague work for a time and then go back to it, do the pains return?—Yes, they come again when one sees patients.

21,955. Does the seeing of a single case of plague suffice to cause the reappearance of the neuralgics?—Yes, when I have seen only one case in a day I have had those neuralgic pains.

21,956. Do you think any element of hypochondriasis can contribute to the causation of these pains?—It may be so, but they are very general.

21,957. Have you heard of the occurrence of these pains among soldiers who knew nothing about pathology?—Yes, they did not generally complain of it, but admitted it when I asked them.

21,958. With regard to corpse inspection, do you think that, in a great number of instances, it is difficult to detect cases of plague by mere inspection of the corpse?—In many cases it is extremely difficult, in fact impossible.

21,959. Have you found in the course of your sick-visitation that it is often very difficult to diagnose a case of plague?—Yes, it is impossible in many cases.

21,960. Do you think bacteriological examination would help you very much in that which you diagnose?—Yes, very materially.

21,961. Have you seen cases resembling mumps which seemed to you to be possible cases of plague?—Yes.

21,962. Have you seen any cases of *pestis ambulans?* I mean cases of swollen glands unaccompanied by serious symptoms which are seen in plague?—Yes, I think I can recall a very small number of cases, in fact only two.

21,963. (*Mr. Cumine.*) You get a history of the case from the friends of the patient, do you not?—Yes, but they give very erroneous statements. We had a case yesterday where we were told that a child had had dysentery for fifteen days. The child was far too well nourished for that to have been the case, and it was put down as a suspicious case of plague.

21,964. (*The President.*) You have always an opportunity of learning the patient's history from friends or outsiders?—We get very erroneous information from them.

21,965. Still, you have an opportunity of examining them and asking them questions?—Invariably.

21,966. Your opinion is not arrived at by inspection?—No, not by inspection alone.

(Witness withdrew.)

Lieut.-Col. W. J. Fawcett, R.A.M.C.

Lieut.-Colonel W. J. Fawcett, R.A.M.C., recalled and further examined.

21,967. (*Prof. Wright.*) Can you tell us something about the neuralgias which develop in medical officers and men who are engaged in plague work?—I presume you allude to what one may call plague neuralgia. I think I first observed it in Poona in the latter part of 1897. Probably the best way of describing the affection is by giving the details of a case. I came across a very well marked case, perhaps one of the most severe, in an officer whose duties did not always bring him in contact with plague, but sometimes for days together he had occasion to be in contact with plague cases and handle them. On each occasion that he handled a plague case, within half an hour afterwards, he had symptoms exactly similar to those which follow the immersion of one's hands in carbolic acid solution, a tingling in the hands extending over the lymphatics of the forearm and before many minutes reaching the lymphatic glands in the axilla. Sometimes it passed off after a few hours, at other times the pains were intensified until the lymphatics felt like burning cords, and the glands in the axilla became extremely painful—a neuralgic pain not increased on pressure. At other

times there were very violent neuralgic pains in the lymphatic glands in the back of the neck, so violent that they quite prevented rest and sleep. This officer never had neuralgia of any kind or description before or since. When I first became aware of this case it led me to inquire among other officers, and I found one medical officer who described of his own accord exactly similar symptoms in himself. At least one Captain and one subaltern on plague duty in the cantonment suffered in the same way. The subaltern suffered aching pains in the groin for the first 10 days after he went on plague duty. He had been on plague duty in two or three different places in India. He had sought relief in remedies of various kinds, but without the slightest result. I did not like to suggest these symptoms to the men, so I asked the medical officers in charge of the two camps, and they told me they frequently had men coming in sick complaining of neuralgia. Two of those men were so bad that they were sent to the Station Hospital. There I observed them, and I have not the slightest doubt that they were suffering from an exactly similar disease. I should like to say that this plague neuralgia is alluded to in print in a popular lecture of mine dated 19th January 1898.

21,968. Will you read us the paragraph?—"I have "found that of those Europeans who have been most "exposed to plague, many have told me that during "the first week or so of their exposure they suffered "from neuralgic pains and stiffness in the groins, "armpits and neck."

21,969. Have you suffered from it yourself?—Yes.

21,970. When you go away from plague work do the pains cease?—Yes. They never last more than a few hours at a time. Many of the officers told me that they became immune after some days. I never did, because my work was not continuous. I frequently did not handle a plague case for two or three weeks, and then mixed with them again during the following two or three weeks. Then I always got the pains again. In fact, so accurate was it, that I used it as a means of diagnosis.

21,971. (*The President.*) Do you mean you could apply this power any time you wished?—Not in every case. I was alluding specially to the first case of plague in a European soldier which occurred in the cantonments. It was a doubtful case, and I examined him with great care, and spent some time in the ward with him. When I reached home I found the tingling had set in in my hand. That was within half an hour. I happened to meet the man who was attending on the patient and I said, "That is undoubtedly a plague case." A bacteriological examination of the bubo made that afternoon confirmed the fact that it was a case of plague. We went back again in the afternoon and he had all the usual symptoms of plague.

21,972. Did you have a similar experience in other cases?—That was almost the last in the cantonment. I noticed it in one or two other cases. I undoubtedly used it as a means of diagnosis in suspicious cases.

21,973. Have you done so lately?—No.

21,974. Would it not be advisable to take an opportunity of doing so?—I do not desire to suffer from neuralgia of that kind again. The power does not last for very long. It would very soon be blunted.

21,975. (*Prof. Wright.*) You said you would make some inquiries with regard to the statistics of the inoculations which were done at Kirki?—I regret to say that although I hold a receipt for a bundle of papers, of which this was one, in the Assistant-Adjutant-General's Office in the Poona district, they are not to be found, but inquiries are being made. Perhaps the Commission might apply to the Assistant-Adjutant-General.

21,976. Before you gave up these reports of the result of the inoculations, had you made a careful study of them?—Yes, and I considered them so untrustworthy that I was unable to draw any inference of any value, or I would have had great pleasure in bringing them to the notice of my superiors at an early date.

21,977. Do you know if a special report other than this untrustworthy report that you speak of was sent to Professor Haffkine with respect to the result of the inoculations?—This was not submitted to Professor Haffkine; it never went further than myself.

21,978. Had Professor Haffkine a special report on the result of the inoculation?—Yes, by another medical officer.

21,979. Do you think the report of the medical officer in question was based on these statistics which you speak of as untrustworthy?—I do not know; I rather think not.

21,980. Were there two medical officers on the spot, one who made the statistics which were submitted to you and another who made a report for Professor Haffkine?—I believe a medical man came down here specially to make a report for Professor Haffkine.

21,981. These statistics which you speak of were made for the information of Government?—I originally obtained these statistics with a view of submitting them to Government, but I found I could not compile anything of any value from them. The young officer had been quite overworked, he was not to blame; he could not possibly keep up with his work at the time, and he seems to have entirely neglected anything like statistical work.

(Witness withdrew.)

Dr. W. D. Betenson called and examined.

21,982. (*The President.*) You are on Plague Duty in Poona, I think?—Yes.

21,983. You wish to make a statement?—I wish to say that I was responsible, to a great extent, for the table (*see* Questions No. 21,416 and 21,788) which was drawn up, grouping the diseases under different headings, to which exception has been taken, and to offer any information that I can with regard to that grouping.

21,984. (*Prof. Wright.*) Was the classification of the cause of death which appears in this table established only on facts observed at the corpse inspection?—No, certainly not.

21,985. It was also made on information received during life?—Yes.

21,986. I find that in your sick visitation you certified 1,900 cases during the year?—There were 1,900 cases of sickness certified by us personally.

21,987. And 600 of those died?—Yes.

21,988. I suppose that those 600 cases with respect to which you obtained information during life by sick visitation are enumerated among the 3,000 cases which came before you in your corpse inspection?—Yes.

21,989. And, therefore, they are included in the table among the 3,000 odd corpses which you examined?—They are included in the table.

21,990. In addition to that there were 2,400 corpses which you had not seen during life?—Yes.

21,991. Then, with regard to the 2,400 corpses, you had no information except that obtained after death?—No, that is not so. The respectable native practitioners sent in to our office, on forms supplied to them for that purpose, a report of all their cases of serious illness, and we received 1,063 of those in the course of the year. As they report serious cases only, the probabilities are that quite three-quarters of the cases which the doctors reported would be found among the 2,400 of which we had no personal knowledge.

21,992. With regard to the 2,400, you have no personal knowledge, but you have had information from native doctors?—To the extent of 1,063. The 1,800 cases are our own, we saw them individually, and each of them had a certificate on the regular form. Then if you add the native doctors' 1,000, you get 2,800 people who were seen in the course of the year by some doctor or other out of 3,035 deaths.

21,993. But some of the 1,063 reported by native doctors you saw while living, and, therefore, they are included in the 1,800 whom you saw during your sick visitation?—Some, but very few. We see on an average, perhaps, three or four a month, and then they would be cases of high fever. We generally write to the native practitioner, if we know him to be a respectable man, and say "kindly send us a longer description of the symptoms of this case," because it is essential not to interfere with the practice of the native practitioners or they would not back us up.

Dr. W. D. Betenson.

24 Feb. 1899.

21,994. Of the 1,063 cases of sickness reported by native practitioners, very few were seen by you?—That is so.

21,995. Then the medical practitioners reported their cases when the patients were practically moribund, is that so?—Most of the native practitioners sent in a report of all serious cases day by day.

21,996. Are the patients, in the majority of cases, already dead when the report reaches you? — Oh, no.

21,997. You say you only saw a few of those cases during life?—We did not take the trouble to see them.

21,998. I thought that every case of sickness which was reported was visited by you?—Not those reported by the native practitioners.

21,999. My difficulty is, that I to-day saw a case visited which had been reported by a native practitioner, and I understood it was your practice to see every such case?—We are more energetic now; if we hear of anybody ill we go and see the case. But, in ordinary times, when there is no plague, unless a man reports a case of high fever we do not go and see it.

22,000. This case which I saw was, as a matter of fact, reported as a case of high fever?—If we have any reason to doubt the report we see the case. I can give you particulars of two cases which were stopped in the city, which are included in our returns of corpse inspection. No details of cases which were sent in were kept until July. After that there were two cases found by corpse inspection.

22,001. You mean the two sporadic cases of plague what were found by you—one in August and one in October?—Yes, they were imported cases.

22,002. The inference you draw from the fact that these two were unreported cases is, that there was plague lingering on at that date in the town?—We have been able to trace every case, I think, up to the 12th February, and we found they were imported from outside.

22,003. You infer from that that the infection died out in the town?—Yes, in May. We had 39 cases imported since. but we can trace them all.

22,004. (*Mr. Hewett.*) Of the 1,063 cases reported by private doctors to you as sick, how many were after-inspected as corpses?—I do not know.

22,005. Will you please get the information?—(The witness subsequently stated that 371 cases were so inspected.)

22,006. Were any of the 106 cases which were found after death to be plague reported to you by doctors in private practice?—No.

22,007. What number of persons whose deaths are recorded in the table do you estimate were not seen in life, either by Government doctors or by private practitioners?—I should think quite two-thirds, 2,000 out of 3,000.

22,008. In case of those 2,000 persons, what means had you of ascertaining whether the record of death which is entered in the table was accurate or not?—We had visual inspection and enquiry.

22,009. What is the nature of your inquiries?—We enquire how long they were ill, and whether they had fever, vomited, or coughed, &c.

22,010. Who made the inquiries?—The medical officer on the spot, through the interpreter.

22,011. Then they were not made direct to the natives of the country by a person who understood the language?—Yes, the interpreter is a native of the country.

22,012. Did the doctor who made the inquiries understand the language?—No.

22,013. (*Prof. Wright.*) Do you think it would be possible, by that method, to distinguish, as you do in your table, between bronchial pneumonia and bronchitis?—The bronchitis in this table includes the bronchitis of old people.

22,014. (*The President.*) But all tables of mortality classified according to the cause of death are full of errors in every country in the world?— Yes, of course this is only rough. The bronchitis includes bronchial catarrh and bronchitis in children.

22,015. (*Prof. Wright.*) Has not the table a fallacious appearance of accuracy? Would it not impose upon anyone who is not a medical man?—Yes, but I maintain they are comparatively accurate.

22,016. Is there not a fallacious suggestion in the table that all these cases are seen during life, whereas, as a matter of fact, two-thirds of them have not been seen till after death?—Yes, certainly. (Note added by witness on correcting proof of his evidence.—No, it is a table of corpse inspection.)

22,017. (*The President.*) You admit the table must contain errors?—Yes, but it is approximately correct.

(Witness withdrew.)

(Adjourned till Monday, February 27, at Satara.)

At The Collector's Office, Satara.

FIFTY-SIXTH DAY.

Monday, 27th February 1899.

PRESENT:

Prof. T. R. FRASER, M.D., LL.D., F.R.S., (*President*).
Mr. J. P. Hewett. Mr. A. Cumine.
Mr. C. J. Hallifax (*Secretary*).

Mr. C. G. Dodgson, I.C.S., called and examined.

Mr. C. G. Dodgson, I.C.S.
27 Feb. 1899.

22,018. (*The President.*) You are Collector of Satara?—Yes.

22,019. You have had experience of plague at Hyderabad in Sind and at Satara?—Yes.

22,020. And have formed some opinions with reference to methods of dealing with plague and the causes of plague?—Yes.

22,021. Can you tell us what your views are about the causes of plague?—I know nothing about the disease bacteriologically. I do not know what plague is beyond that it is a bacillus of some kind or other, but I believe plague may be spread by rats. I do not know that it is, but I suppose it is, because rats frequently die before human beings; but I think that, probably, the spread of plague is mainly due to human agency. I think people take it about in their clothes, and possibly, for all I know, they may eat it. I mean that I have seen people sitting alongside a plague patient in a hut eating food off the ground, with the patient lying within a few inches of the food; it is therefore quite possible that they are eating bacilli at the time.

22,022. Have you any case which seems clearly to show that the disease can be communicated by human agency?—I have known a man go to an infected village, stay there for two or three days, or even less, and come back to his own place and at once infect his family.

22,023. That would include his clothing, probably?—Yes, he had probably brought the infection in his clothing. I have known cases of a person coming in that way from an infected place to his own house, and his own family getting the plague, he himself not getting it.

22,024. Have you any case in which clothing, apart from persons, appears to be the conveying agency?—There was a case two or three hundred yards from this bungalow. A man last year, who was a storekeeper in the camp at Satara, went, after the plague was over, and lived in this village of Kamatpura. A month, or two months afterwards, plague broke out in Kamatpura, and the general opinion was that this man had been stealing the clothes from the dead bodies of women in the camp, and then giving them to his own wife. His wife was the first person who got the plague—he himself did not get it, but the rest of his family got it, and they nearly all died.

22,025. What evidence was there that he had really been taking infected clothes?—The clothes were found in his house, and he could not account for them. Of course, there was no real evidence, on which we could have secured a conviction in a criminal court, that he had stolen them, but that was the general opinion among his relatives and neighbours.

22,026. Do you think it is possible to prevent the spread of plague from one place to another?—No.

22,027. Why?—Because you cannot thoroughly control the people. You might, if you had an unlimited staff and unlimited money, but we have no money and next to no staff here, and we cannot, therefore, control them.

22,028. The people will not voluntarily do what is required?—No. We have very frequently to prosecute a man for leaving an infected place and going to another village without permission, but it is only one case in 50, or one in a hundred, that we actually get hold of.

22,029. In regard to dealing with plague when it has occurred, what, in your opinion, is the most effective of the measures which can be adopted?—If the object merely is to stop the plague, I should say the only thing was evacuation, and segregation of the contacts and the patients.

22,030. Evacuation of the infected area?—Yes, of the infected quarters, or whatever it might be; that is, if the only object is to stop the plague, quite regardless of the feelings of the people and their wishes.

22,031. But as a practical measure, what do you consider the most effective for stopping the plague?—Trying to evacuate, and evacuating as much as possible.

22,032. The more evacuation, the more effective this measure is, in your opinion?—The more evacuation, the more effective I think it is.

22,033. Have you any instance in which, by evacuation, you have been able to stop the extension of plague in an infected village?—I have some figures which I have had worked out which show that, in some cases where plague has broken out in a village and the village has been evacuated, plague has stopped at an early date.

22,034. Would you illustrate that with your figures?—There are many other figures, I admit, which show that if you evacuate the place plague does not stop at an early date; it goes on for a long time.

22,035. Would you give us the figures?—There is a village, Taruk, where the occurrence of the first case of plague is shown as on the 25th November 1897. The village was evacuated, and all the people are reported to have finally left the village on the 2nd of December. There had only been three cases there, and no more occurred after the village had been evacuated. There is also another case of the village of Nandgaon, which was infected on the 15th of November 1897. The people were all out of the village on the 22nd—there had only been four cases previous to, and three more during, evacuation, and no more occurred after evacuation.

22,036. How large are these villages?—Taruk has a population of 1,559, and Nandgaon has a population of 1,402. Then, again, Garawadi, with a population of 1,599, was infected on the 5th October 1898, and the people were all out on the 10th October 1898. There were three cases in the village, and three cases after they went out, and that was the end of it.

22,037. Do you know at what interval of time the majority of cases after evacuation occurred, and whether any of those which occurred two weeks and afterwards could be accounted for by fresh importations?—I produce a statement which shows villages in which the number of cases began to decrease soon after evacuation:—

Mr. C. G. Dodgson, I.C.S.

22,038. Can you give us examples of other villages in which evacuation was not successful?—I may point to Mahuli. Mahuli has a population of 1,959. It had 17 cases before evacuation. The people went out two days after the outbreak, and they had 138 cases afterwards, but that was the end of the epidemic. And there is another case here—I do not know what happened in this village, but it is rather peculiar. The village is Ving, with a population of 4,424. Plague broke out on the 4th September 1897, and the village is said to have been completely evacuated on the 13th September; there was one case before they went out, and 295 after they went out.

22,039. So that evacuation was not successful. Have you any explanation of that?—No. I do not know the exact circumstances of the village. I have been to it lately, but the epidemic I speak of occurred in the winter of 1897-98, and I was not in the district then. I came to this district in February 1898.

22,040. Who could tell us about this case?—The Collector then was Mr. Winchester, but he has retired now. There is also a Staff Corps officer, Lieutenant Steen, who was here then.

22,041. Have you other instances in regard to which you have more detailed information?—Here is the case of Vathar, with a population of 1,646. Plague broke out on the 1st June 1898, and the village was reported to be evacuated on the 5th. There were six cases before the people went out, and 204 cases after they went out. I know about Vathar. I went there myself last July. It was raining very hard at the time, and although the people were nominally out in the fields, they were not living permanently in them; they could not do so owing to the rain, and they kept going back to their houses. The day I walked through the village we found a lot of houses occupied that were supposed to be empty.

22,042. This was not really an instance of evacuation?—No. The large number of cases after nominal evacuation undoubtedly was due to the people continually returning to their houses.

22,043. Have you any other case?—Aundh is a Native State village. Plague broke out on the 11th October, and evacuation is said to have been complete on the 15th October. There were five cases before completion of the evacuation, and 165 cases afterwards.

22,044. What was the total population?—3,248.

22,045. How do you explain this failure?—That being a Native State village, it was very badly looked after, and it was never really evacuated, although it was officially reported as having been—all the upper classes, the Brahmans, for instance, were never turned out of their houses.

22,046. What has been the general impression produced in your mind in regard to complete evacuation where it has been properly carried out?—That the

Mr. C. G. Dodgson, I.C.S.

27 Feb. 1899.

plague undoubtedly does begin to decrease soon after the people have gone out—within, I should say, a fortnight.

22,047. In regard to some of the villages where the evacuation was unsuccessful, have you any knowledge of the nature of the huts in the camp to which the people had removed?—They are generally huts of a most primitive type. In many cases they consist merely of a few sticks of karbi or grass put up as a lean-to for protection against the sun.

22,048. Is there any exceptional condition with regard to the huts in those camps where you had no success?—The absence of success is chiefly due to the rain, not to the nature of the huts. The people build their huts much more solidly during the rains than they do at this time of the year. During the rains they are tighter and closer, and are like little bee-hives, with a little door which you can just walk in at, and there is, practically, no ventilation whatever.

22,049. This is confirmatory of what you have expressed, that unless you secure free ventilation you do not greatly lessen the progress of plague?—Exactly.

22,050. In addition to evacuation, what other measures do you consider important?—I think you have to make a distinction between large towns—I mean a place like Hyderabad, in Sind, for instance, with a population of about 60,000, and one of these little district villages, with populations of from one to three or four thousand. In these small villages, I think, the patients and their relatives ought to be segregated. They can be segregated fairly effectively.

22,051. That is, in addition to evacuation?—Yes. Without segregation there is no knowing where the members of an infected family go to; they wander all about, and get mixed up with their friends and relatives, and spread the infection.

22,052. In the evacuation camp, you mean?—Yes. But in a large town it is very much more difficult to segregate the contacts and the patients. If it can be done, I think it is undoubtedly a good measure, but, of course, there are great difficulties in the way, because the people hate the idea of being segregated. They do not generally resist actively—they do sometimes, and then the only means is to use force.

22,053. Which would be objectionable?—Yes. It may be a good thing for stopping the plague, but it is a bad thing for anything else.

22,054. In regard to evacuation, in dealing with large towns, what opinion have you formed?—The same idea; if you can get the people out, well and good.

22,055. It is desirable, but not always practicable?—Yes, without a great deal of opposition.

22,056. Are there any other plague measures that you consider valuable?—I believe in letting in fresh air and sunlight into the houses, keeping the windows open if there are any, and opening the roofs.

22,057. If there are no windows?—If there are no windows, in the majority of houses one might make holes in the wall, but sometimes that is not possible, owing to the walls being too thick, or the houses being too badly built.

22,058. What is your view about disinfection by chemical substances?—I have tried it in Sind, and here last year; and we did it here on a very large scale. I do not think it is necessary—I do not mean to say that it does not kill the germ—I do not know whether it does, or does not; but the germ, I think, certainly dies without it.

22,059. If ventilation has been freely done, you think, then, that chemical disinfectants are not required?—Yes, I think so. It may take longer for the house to become habitable; but the house does become habitable sooner or later.

22,060. Have you any examples in which, without opening up a house so as to admit light and air, chemical agencies only were trusted to?—Yes, we did it in Sind. Some of the houses could not be opened up owing to their thick walls and entire absence of windows. There we used only chemical disinfectants, and the house was not opened up; but the plague did not occur again.

22,061. At what interval of time after disinfection were the houses reoccupied?—I was not there when the people were readmitted, but I think it was about two months after the people had been turned out. I have seen the Sind report, and, as far as I can remember, this is what I gathered from it.

22,062. You have had no examples of re-occupation following chemical disinfection at a shorter interval than two or three months?—We have had a case in the town here quite recently. There was a very well-built house outside the gaol, belonging to the gaoler—a house built very much like this, with plenty of windows. There was a case of plague there, and the house was disinfected with perchloride of mercury, and the people went out. On their return, after 10 days, there was a case of plague almost immediately, and the patient died.

22,063. You think the interval should be a long one?—Yes; but I would not trust to that alone.

22,064. What is your experience with regard to the influence of rats in propagating or causing the disease?—Rats undoubtedly die of plague, because one finds hundreds of them that have died in infected places; and I think they certainly die before human beings. I suppose that they carry the plague about from one house to another; otherwise, I do not see how it can spread, because it certainly spreads in an evacuated village. I mean, after the village has been evacuated, the infection does spread from one house to another.

22,065. What is the evidence of its spreading?—You can take a village with a few infected houses at one end, or in one quarter, and turn all the people out; but you constantly find that when the people go back to the other end of the village, or to a hitherto uninfected quarter, and sleep there without permission, they get the plague. There are many cases of this kind. I suppose rats have, in such cases, carried the infection, because I cannot think of any other means of locomotion for the plague.

22,066. Do you know if plague is spread by any other animals?—It may, perhaps, be spread by squirrels and monkeys. I have been told that dead monkeys and squirrels have been found, but I have not seen any.

22,067. Have you any opinion to offer as to the means by which infection seems to extend in certain directions from the originally-infected area?—I have seen it go across one side of the street, but it is rather slow in crossing.

22,068. Do you mean that it usually extends by continuity of dwellings?—Yes.

22,069. Supposing there were an interval between two dwellings on one side of the street, would you expect it to stop at that interval?—No; it would get across, but it might be delayed by this interval.

22,070. Why, then, would it not get across a narrow road to the other side of the street?—It would cross it finally, but it would be delayed. If there was traffic up and down the road, this would probably make the rats more chary in crossing the street.

22,071. That would apply more to the day-time than to the night?—Yes.

22,072. Rats are more likely to move about at night?—I suppose they are; but rats burrow from house to house at closer intervals than the breadth of a broad street, with probably traffic going on over their heads.

22,073. Have you any example to show that grain has been so infected with plague as to convey infection to man or the lower animals?—No. I have never heard of a case.

22,074. (*Mr. Hewett.*) What was the maximum number of villages which you had infected in the Satara district at any one time?—It was 114 on the 25th November 1898.

22,075. At what period of the year do you find that plague is most prevalent?—I do not think it matters much. As far as we have seen hitherto in the two epidemics in this district, there is less plague in the hot weather. For instance, it began to die out last year about the month of February, and practically stopped in April, when the weather got hot. This year it seems to be doing the same; but in both years it was very bad from July up till February, *i.e.*, during the rains and the cold weather.

22,076. Is it not practically impossible to evacuate a village on a black cotton soil during the rains?—We did evacuate such villages, but the evacuation was not thorough; and the people constantly went back to their houses.

22,077. You cannot keep the people out of the village site?—No, not in rainy weather; it was practically

impossible, as they cannot continue to live up to their knees in mud and water. If they do that, then the plague is probably just as bad outside as it would be inside the village.

22,078. When the plague broke out afresh after it died down to a certain extent in the hot weather last year, did it reappear in the same villages as had previously been infected, or in new ones?—Mostly in others, I think.

22,079. Do you remember whether those others were in the immediate neighbourhood of the villages which had been infected before?—Yes, they were, but the infected and the non-infected villages were fairly distributed all over the country.

22,080. Is it your general experience that a village adjoining a village infected in the first epidemic got infected in the second epidemic?—Not necessarily, but plague has run down the western part of this district fairly regularly. Excluding the hill portion of the west, it has run down a broad strip, perhaps 30 miles wide from north to south, and it has been mostly confined to that strip in both epidemics.

22,081. Has a village infected in the first epidemic, as a rule, escaped in the second?—Yes, I think that is so; if they have been attacked in the second epidemic, it has generally been in a milder form than in the first epidemic.

22,082. (*Mr. Cumine.*) Do you remember what the population of the district is?—About 1,225,989.

22,083. How many Staff Corps officers or other special European officers have you for plague work at the present time?—Five Staff Corps officers and one English doctor.

22,084. With so few European officers to work against plague, and with such a large population and so many infected villages to deal with, do you think it possible to work plague measures against the active opposition or even the passive opposition of the people?—No, not satisfactorily. You can do a great deal in the way of evacuation and segregation, but it is never perfect. I mean, supposing the European officer has perhaps 12 or 15 villages, actually reporting plague at the same time, and scattered over an area of, perhaps, 200 square miles, he can only go to each of these villages once or twice a week. While he is there he does the best he can, and gets arrangements more or less into working order. Then he goes away and does not return for, perhaps, a week, and he then probably finds his contact camp empty and his village practically re-occupied, and he has to begin all over again.

22,085. To make evacuation yield its maximum amount of good, it has to be accompanied by two or three complementary measures, such as cutting off the people from the infected village site and getting them to isolate their sick, has it not?—Yes, certainly.

22,086. Where a Staff Corps officer has about 15 villages to look after, can he carry out these complementary measures which are necessary to make evacuation have its full effect?—He can only start them, and then trust to his subordinates, the Hospital Assistant, and the Plague Circle Inspectors, and the Mamlatdar. He must trust to them to try and keep the measures in working order.

22,087. But, personally, he cannot see to them?—No; he can only start the arrangements and must trust to his subordinates to carry them out, and keep them going regularly.

22,088. If every plague stricken village is evacuated, the people are unable to contrast what happens in a village which is evacuated and where the people are prevented from communicating with the infected site and made to isolate their sick, with a village in which the people do not go out at all and nothing whatever is done. That contrast is not before their eyes, is it?—No.

22,089. Do you think it would be better, and have a greater educational value, if each Staff Corps officer confined his attention to two or three villages alone close to one another, and made evacuation completely effective in them, and managed to stop the plague in them within a week or ten days, and thus enabled the villagers all round to see what the maximum amount of good is that evacuation can do? Do you think that would be a better plan than the present one?—In some ways it would; but as against that you would have the fact that the people frequently evacuate themselves. As soon as they really get scared, and realise that there is a dangerous epidemic among them, they go out of their own accord without any driving on the part of the European officer. Of course, having gone out, they would not segregate in the sense that we would; they would not bring all their sick into one field and call it their segregation camp; each family would move its patients away, very likely, from the family hut, and put them in a hut 10 or 12 yards away.

22,090. Would they boycott anybody who went into the village and brought back infection, thus nullifying all the good results achieved?—They would give information to the authorities if he was a low caste man, but not if he was a Brahman.

22,091. The extent to which evacuation produces good results depends largely on the season, I think I understood you to say—that is to say, in the rains evacuation produces hardly any good results whatever?—Hardly any.

22,092. Does it depend to some extent also on the employment of the inhabitants? That is to say, if a village is a purely agricultural one, I suppose the people do not feel going out so much as if they were Banniahs and Marwaris?—No, the ryots go out quite readily, but the traders object.

22,093. Do you remember inwhat villages the plague appeared first of all, what month it was, and in what part of the district? The reason I ask is that we have had a theory laid before us that the germ, if imported straight from Bombay into a dry open *desh* village, appears to be unable to infect the village; that it requires a damp place like Lanauli as a half-way house to get partially acclimatised in before it can infect a dry *desh* village?—We have had cases brought from Bombay here, but the present epidemic came from the Sangli State, a Native State in the South. The first infected village in this district was a village called Sangwi. That was infected in October, 1896, and the infection came from Bombay. I was not there, but I think it is so. The present epidemic certainly came from Sangli, although villages have got the infection from Bombay. The infection lingered on in one or two villages in the south of the district during the hot weather of 1898. Then it got worse in Sangli, which is just over the border, and it gradually spread northwards into our district. But there have been cases of plague coming up from Bombay, and villages have been reported to have been infected owing to this. It is very difficult, however, to get the exact truth as to how a village does get infected. The following is a short account of the manner in which this district has suffered from plague. The first village to be infected was, as I have already stated, Sangwi, which has a population of about 700. A man came up from Bombay with plague and the result was that in a few days the disease spread in the village and 38 people were attacked. The first case in this village occurred in October, 1896, and the last case in February, 1897, but the disease did not spread from here to any other village. On the 16th February 1897 the village of Akhade, in the Javli Taluka, was found to be infected, and on the 27th February 1897 a neighbouring village called Waluth was found to have been attacked. Both these villages were infected from Bombay and not from Sangwi, which is more than 20 miles from either of them. About the same time cases began to occur in Phaltan, a small Native State in the north of this district. This was practically the whole of the epidemic of 1896-97, the total number of cases being only 88. The last case in 1896-97 occurred in the week ending 10th April 1897 at the village of Bahule (Taluka Patan). The district then remained free till the 9th July 1897 when plague broke out at Karad, a town with a population of 13,209. As a matter of fact, there is reason to believe that there was plague at Karad before this date, but it was not officially reported. From Karad a case went to Kaledhon, a village some 35 or 40 miles further east, and from these two centres the epidemic spread rapidly in all directions, especially around Karad. The weather was raining at the time, and owing partly to want of staff, partly to the weather, little could be done for a long time. From July to December 1897, the epidemic was very severe. It was chiefly confined to the two talukas first attacked—Karad and Khanapur. The town of Karad alone had 1,457 cases, and the Karad

Mr. C. G. Dodgson, I.C.S.

27 Feb. 1899.

Taluka had 6,448. The total number of cases in the district during 1897–98 was 15,186. The town of Satara with a population of about 25,000, was infected from Karad, although a case was also imported from Bombay. The epidemic began in the month of October 1897, and lasted until April 1898, the total number of cases being 720, with a death-roll of 612. Evacuation was freely resorted to everywhere, both in towns like Satara and Karad, and small villages and everywhere it seemed to be the only effective measure. In other words, there was nothing for it, but for people to run away from the infected spot. The last case in Satara Town occurred on the 4th April 1898. No further indigenous cases occurred in Satara City until 7th October 1898. Since then the disease has lingered on making but little progress, the cases varying from about 3 to 10 every week, and every fresh centre being met by the evacuation of the surrounding houses. The district has practically been never quite free since its severe attack in 1897–98. No cases were reported for a few days in April and May, but plague lingered on in two or three villages in the south throughout the hot season of 1898. It gradually became worse in June and July and spread northwards until at the end of November over 100 villages and hamlets were infected. We have throughout tried to meet it by means of evacuation of the infected quarters and segregation of the sick and their relatives, and in 1897–98 we made a free use of perchloride of mercury as a disinfectant, many villages being disinfected from end to end. This year, we have used very little in the way of chemical disinfectants as they are too expensive, and their benefits open to question. We have also always insisted on ventilating all infected houses, making holes in the walls and opening the roofs. A little inoculation with Prof. Haffkine's serum was done, chiefly in Satara Town, but the people did not take to it readily, and the experience we had with it has been too small to justify any conclusions being drawn.

22,094. You spoke, I think, of the advantages of segregation in a town, but you also said that even after a village has been thoroughly evacuated, the plague seems to have the power of spreading by itself from house to house. If that be so, does that not discount to a great extent the advantage of segregation?—It does to a certain extent, certainly, but the fewer people there are in the town, the fewer there are liable to get attacked, and the fewer the plague centres from which the plague may spread.

22,095. Has it been noticed at all whether the second epidemic in this district was milder or more severe than the first one?—I think the percentage of deaths on attacks is very much the same as it was last year, but the number of cases is somewhat less; for instance, in the epidemic of 1897–98 there were 15,906 cases in the district, whereas during the present epidemic there have been up till now only a little over 10,000 cases. The cases have been fewer, but the death-rate is about the same.

22,096. (*The President.*) More virulent?—About the same virulence, I should think, as last year. About 75 or 80 per cent. of the infected cases die, I should think.

22,097. (*Mr. Cumine.*) You have a Civil Surgeon in the district. Have you any other European doctor permanently stationed in the district?—No. We have one on plague duty temporarily, and there is a Civil doctor at Mahableshwar. He is Superintendent of Mahableshwar, but he does not help us in the district.

22,098. As regards the inspection of corpses, do you think that the Natives would have much objection to inspection of corpses by European doctors?—I do not think they would have.

22,099. Do you think the Musalmans would have any objection to corpse inspection by a Hindu doctor, and the Hindus to corpse inspection by a Musalman doctor?—They would not in this district, because the ordinary Muhammadan here is of a very low type, he is half a Hindu; but in Sind, I think, they certainly would object.

22,100. Have you any reason to suppose they would object in this district?—I do not think the Muhammadans here attach very much importance to their religion, they are much the same as Hindus.

22,101. Do you think they would object to having the corpses of their women, for instance, examined by anybody, whoever he might be?—A doctor can answer that question better than I can, but I think several Muhammadan womens' corpses have been examined by European doctors. Here, in Satara, they generally are examined by the lady doctor.

22,102. If it were to be done by European doctors alone, the town of Satara is the only place where it could possibly be done, is not that so?—That is the only place where we have a doctor to do it.

22,103. The Civil Surgeon of Satara has a great deal of other work to do, has he not, in looking after the Civil Hospital and the Jail and the town?—Yes.

(Witness withdrew.)

Lieut.-Col. H. Hay, I.S.C.

Lieut.-Col. H. Hay, I.S.C., called and examined.

22,104. (*The President.*) You are in the Staff Corps?—Yes.

22,105. And Chief Plague Authority in Satara?—Yes.

22,106. How long have you been here?—Since the 7th of October 1898.

22,107. (*Mr. Hewett.*) You had some prior experience of plague elsewhere, had you not, before coming here?—Yes, I had four months in the Thana district at Bhiwandi.

22,108. What is the population of Bhiwandi?—15,000 is the normal population, but during the epidemic it went down to 7,800. I took the population by census.

22,109. When did you go there?—I went there on the 28th of May 1898.

22,110. At that time what was the strength of the population?—About 12,000.

22,111. About how long had plague been present when you got there?—They had a few straggling cases, within the month of May, for about a fortnight.

22,112. When did the epidemic begin to be bad?—About the 15th June 1898.

22,113. And how long did it continue?—It continued till the end of September.

22,114. During that time what measure did you take?—We were instructed by the authorities to deal gently with the people, without the application of force, and to try and get them to co-operate with us in checking the spread of the disease.

22,115. Were the people mainly Hindus?—No, a large number of them were Muhammadans—Momins.

22,116. Did you evacuate the town, or did you restrict yourself to removing patients from infected houses?—We treated most of the patients in their houses at their earnest request.

22,117. Did you find that that was a good measure or not?—I found that it was a very bad measure.

22,118. Why do you think so?—I have some carefully collected figures here of Dr. Ernest Hill's, the Chief Medical Officer at Bhiwandi. The collection was made at the end of the epidemic. From these figures it appears that, supposing one case occurred in a house, it was 100 to 3 against an inmate getting plague if he went at once into segregation, or if he attended his friends in hospital outside; but that if he remained there, out of every hundred, at least 16 were taken.

22,119. How many people went to hospital?—153 persons actually went to hospital, and 1,625 were treated in their own houses.

22,120. Can you say how many people got the plague by reason of being attendants on sick persons?—I cannot say that.

22,121. Did you disinfect the houses in which these people lived?—All those houses were disinfected.

22,122. While the people were actually suffering?—No, not until they either died, or were discharged.

22,123. Was there no attempt at disinfection in a house while a case was being treated?—Never.

22,124. Did you notice in Bhiwandi any mortality among rats?—A great deal.

22,125. Did that occur immediately after your arrival there?—I think I observed it about a fortnight or so

after my arrival, but others had remarked it before I arrived. In one of the worst infected quarters of Bhiwandi I remarked a bad smell emanating from a shop which had been closed for two months. I forced the door open, and on entering, discovered several dead rats. One rat was actually dying. It was crawling across the floor, and I killed it with a stick. I ordered the rat holes to be opened up, and I discovered no less than 57 dead rats in various stages of decomposition. Some of them were skeletons. They had burrowed into the walls and into the floors. Plague was raging on all sides of this shop which apparently was the centre of infection from which diseases radiated. It seemed to be the exact centre, as plague was very bad all round there. I thought that a notable case.

22,126. Were you able, by your inquiries there, to make out that the mortality among the rats began before any imported case of plague occurred?—No, I could not say that.

22,127. Did you notice that any particular classes of persons were immune?—I did. I noticed that the rice cultivators were a very strong example of that. They numbered 600 or 700, and they lived in very small huts in the midst of this epidemic. Their occupation took them out from morning till night in the heavy rains—transplanting rice. They had not a single case amongst them. They were continually in the open air, while the other people were shut up in their houses with the windows and doors closed. These people were working outside the whole time.

22,128. Did you notice that any particular class was especially subject to attack?—No; I only noticed those who lived in huts, and in inferior dwellings with bad ventilation. The worst portion of the town from a sanitary point of view was the worst infected spot. I noticed that the fakirs were immune. A very large number of fakirs come to Bhiwandi. They pass through it on their way to somewhere. I never heard of a single case amongst them.

22,129. Muhammadan fakirs?—Both Muhammadan and Hindu. They live an out-door life; and I think that is the reason why they do not get attacked.

22,130. Did you come from Bhiwandi to Satara?—Yes, straight.

22,131. What is the population here that you have had to deal with?—I have had to deal with about 19,000.

22,132. In the town?—Yes, in the town.

22,133. How many cases of plague have occurred since you came?—Only 146.

22,134. Have cases occurred among any particular class of people, or in any particular section of the town?—Cases have occurred chiefly amongst the poorer classes of people who live in the poor houses.

22,135. Have cases occurred in houses in which there were plague cases last year?—That is the remarkable thing about it. Many of the divisions which were badly infected last year are not infected at all this year.

22,136. Were the houses in which plague cases occurred ast year disinfected?—They were all disinfect

22,137. Has any instance come to your knowledge of a case of plague recurring in a house which was disinfected last year?—Yes; I can give you a case. This is the case Mr. Dodgson referred to—the Head-Jailer's house. That, I think, was a very strong example. That house became infected on three separate occasions, after having been thoroughly disinfected three times with a solution of perchloride of mercury, 1 in 1,000. It is a large stone house, built by the Public Works Department, with a galvanised iron roof, and very well ventilated. The Jailer's daughter was seized with plague on the 9th January 1898. The house was immediately evacuated, and disinfected with perchloride of mercury. When general disinfection of the whole town took place in the following month by the order of the Collector, this house was again disinfected with perchloride of mercury, but, notwithstanding this double disinfection, a second case of plague occurred on the 20th of December 1898, when another daughter of the Jailer was seized with plague and died. Again the house was evacuated, and disinfected most thoroughly with perchloride of mercury under my personal superintendence. The Jailer and his family returned to the house on the 31st December 1898, and 10 days after both the Jailer and his wife were seized with plague and succumbed, after an illness of 24 hours in the case of the husband, and 48 hours in the case of the wife. As a result of a most searching inquiry, these cases are not traceable to any other cause than the house. The family kept practically aloof from outside infection, and they were very particular about it.

22,138. Do you think it possible that any clothes remained in the house which were not disinfected?—I do not think so. Everything was cleared out, and all the belongings of the deceased were burnt.

22,139. Were all the belongings of the daughter burned in the first instance?—I believe so. It is the practice. I, however, was not here then.

22,140. Were all the clothes of these people disinfected when they went out?—They were, before they left hospital to return to their house.

22,141. I mean when they left their house; were all the clothes of the people who went out disinfected?—The clothes which they took with them to the hospital were disinfected before they went back.

22,142. Did they leave any clothes inside the house?—I am not aware of it. I saw the house was completely gutted out.

22,143. On the other hand, I understand that you have noticed that the houses which were infected last year have escaped this year?—I have noticed that in a very marked degree.

22,144. Although they are in the neighbourhood of places which were infected?—Yes, in the neighbourhood.

22,145. In addition to your work in the city, you have had to do with villages in this taluka?—Yes, and the suburbs, which include cantonments.

22,146. How many villages have been infected in the taluka?—57 villages have been infected this year.

22,147. Have you noticed that the villages in a particular situation have been specially liable to infection?—I have noticed all the towns and villages on the banks of the river Krishna in particular. I have brought a map* with me to show the Commissioners what I mean. All the villages on both banks which were infected this year are marked in red. You can contrast it with the other portion of the taluka away from the rivers, where there has been very little plague.

22,148. It would appear from the map that many of the villages on both sides of the river have been infected, but comparatively few away from the river?—Practically, it seems to have confined itself to the Yenna and the Krishna.

22,149. The chief difficulty which you find is in getting early notification of the existence of the disease, is it not?—That is the difficulty which we have; but as time goes on, and the people become educated, and understand the advantages of giving early information, we have not had that difficulty so much.

22,150. Is that difficulty due to the people not wishing te report, or to the fact that they do not know when plague is among them?—The reason is because they do not wish to turn out of the village—the inconvenience.

22,151. Do you think that is the only reason?—That is the chief reason.

22,152. Do you think that they generally know at once that plague exists among them?—I think nearly all the villagers know it now.

22,153. Have you had pneumonic plague here?—I have only seen two cases of it. I do not think there has been much pneumonic plague.

22,154. Have you tried inoculation?—Yes, we have; but to a very small extent compared with the size of the place. We have only 691 people inoculated in the city out of a population of between 18,000 and 19,000.

22,155. Have people shown no desire to be inoculated?—No. I have tried every means in my power to persuade them, even to the extent of promising readmission to their houses; they have been promised that those who have been evacuated should be allowed to return if they would be inoculated; but it has had no effect upon them at all.

22,156. Have you any results as to the effect of inoculation?—I have a few. The Pet (or ward) called Rawiwar which is inhabited by Mahars and other low caste people, has 68 houses and a population of 292. In December 1898 it was found necessary to evacuate the Pet, as cases had occurred in 13 houses. Out of this population of 292, 107 had been inoculated. As an

* Not published with the Proceedings of the Commission.

Lieut.-Col. H. Hay, I.S.C.

27 Feb. 1899.

experimental measure, at the suggestion of Dr. Thomson, I allowed those who had been inoculated to remain. No case has occurred amongst them up to date, although the area in which they have been living must have been full of plague germs, infected houses being on all sides of them, some actually touching.

22,157. Have the houses been disinfected?—Yes, with perchloride of mercury; and the roofs have been taken off—or, rather, a portion of the roofs—about 3 feet broad.

22,158. Did the people who went away without being inoculated have any plague among them?—Yes, they had; but I could not give you the numbers.

22,159. Did you place those people whom you took out of their houses in camp?—Yes, they were placed in camp at Godoli.

22,160. Do you know whether they had plague in the camp?—Yes, they had; but I do not know how many cases.

22,161. Was anybody supervising them while in camp?—Yes, we had a Hospital Attendant, and the doctor visited it daily. The medical officer would know the exact number of those people who were afterwards attacked with plague. Dr. Smith will be able to give you the information.

22,162. Do you think that disinfection is a useful measure?—Yes, as a repellent, but not as a destructive agent. The second epidemic in Satara, in my opinion, might have been as bad as the first (it is very much less this year, about one-third, or something like that) had it not been for this general disinfection ordered by the Collector of all houses, which was carried out early in 1898, before I came to Satara. I think that has had the effect of stopping the spread of plague in every house that was disinfected. I think disinfection makes the area less palatable for the microbe. That is to say, if you took two houses (one which had been saturated with perchloride of mercury, and the other had not), I think it would prefer the one which had not been disinfected.

22,163. How can this be if the bacillus does not travel about at a rapid rate?—I think it has been kept aloof, to a certain extent, by perchloride.

22,164. Would you not expect that, if a disinfectant had this repellent effect, it would also have a destructive effect?—It does not seem to have been strong enough in a case like the Jailer's house.

22,165. Can that be in any way due to your solution of perchloride of mercury not having been of the strength you thought it was?—No; I am very particular about mixing it. I have it done under the superintendence of a medical officer once a week. The strength is 1 in 1,000.

22,166. One of the measures which you think of extreme importance in dealing with plague is the system of what you have described as perfect surveillance; what do you mean by that?—The town is divided into 24 Pets, and each Pet has an honorary secretary: and under him he has so many voluntary helpers. Every morning they go round to the houses. They have a little census on the wall outside, with the number of the occupants of each house, and their names. They have a sort of roll-call every morning; and if they find an additional member of the family they inquire into the newcomer's antecedents, where he or she came from. The medical officer goes round periodically and examines those people; and in that way it has been found that plague cannot get to any great dimensions without our knowledge. I am kept informed every morning of the result of these house-to-house visitations. For 10 days after people arrive from Bombay they are under this surveillance—visited daily.

22,167. In order to carry that out you have to rely upon the active co-operation of the people themselves?—Yes, upon the active and intelligent co-operation of the people themselves.

22,168. I suppose they are moved to that by the fact that they had these two outbreaks in the town?—Yes; they work very willingly.

22,169. Supposing you were dealing with a large town which had not been unfortunate enough to have suffered already from plague, do you think that the people would realise the extreme importance of keeping an eye upon new arrivals?—No; I think this is the result of the education which the first epidemic has given them.

22,170. That would be a great difficulty in dealing with a newly-infected town, would it not?—Yes, it would.

22,171. (*Mr. Cumine.*) Were there two epidemics in Bhiwandi?—Yes, two.

22,172. Were you present at both?—No, only the second.

22,173. During what months did the first epidemic prevail?—The first epidemic was imported from Bombay, and began in December, 1896.

22,174. How long did it go on?—It lasted up to the middle of April, 1897.

22,175. How many deaths were there in all?—491 cases and 434 deaths.

22,176. Do you know to what extent the people left the town?—Nearly the whole of them left. Dr. Dalal, who was in Bhiwandi, in comparing the two epidemics, said that the mortality being so small in 1896, and so great in 1898, one would naturally ask the reason for the difference. In 1896 there were 491 cases, and 434 deaths, and in 1898, 1,788 cases, and 1,255 deaths. He explains this by the fact that plague broke out at a different season of the year in the second epidemic; and that the people of their own accord left the town and went into huts during the first epidemic. During the second epidemic we were prevented by the rains, which confined the people to the town, and which, consequenty, made a great difference in the mortality.

22,177. Is it within your knowledge to what extent the plague in the second epidemic visited the same houses as it did in the first one?—It is within my knowledge that it visited the same houses and the same quarters.

22,178. I do not quite understand your ground for saying that the treatment of the sick in their houses had a bad effect at Bhiwandi?—I will tell you. The reason was this. These houses were so close together and thickly populated that it was utterly impossible to isolate the sick. I had to institute prosecutions in several cases of surreptitious visitations—generally by night—of the friends of the patients, who would go and sit alongide the bed, and in that way help to spread the disease into the town. Constant intercourse between the sick and the healthy outside is the evil effect of house treatment. I found I could not stop it by prosecution.

22,179. Did you distinctly trace cases of new infection to a visit to a sick person?—Yes, very often.

22,180. Did you put the patients on beds?—When we could.

22,181. But not always?—No, not always.

22,182. If you left the patient lying on the floor, and if you did not disinfect the floor daily, then the treatment of the sick in the house did not have a fair chance, did it?—I do not think it had a fair chance. In many cases they were lying on cow-dung floors.

22,183. You did not disinfect the floors daily?—Not until the patient was disposed of, either by death or discharge.

22,184. You spoke of rice planters being exempt. Are the rice planters out working in their fields during the night?—No, they are not; but they spend a very short time in their houses. They get up very early in the morning, before daybreak, but they sleep in the houses.

22,185. Did you carry out any corpse inspection at Bhiwandi?—Yes, we carried it out.

22,186. Did you strip the bodies?—They were not all actually stripped; they were examined to see whether they had plague or not.

22,187. By whom?—By the Hospital Assistant. The bodies were not allowed to be disposed of until a certificate was sent by the Hospital Assistant.

22,188. Did a European always accompany the Hospital Assistant?—Not always.

22,189. Supposing no Europeans had been there, do you think the people would have permitted the inspection of their dead by a native Hospital Assistant?—I do not think that the Memons would. They would not allow their women corpses to be inspected. I have a chart* here, which I made yesterday, on the Bhiwandi epidemic, showing where the people were treated in their houses.

* Not printed with the Commission's Proceedings.

22,190. (*The President.*) Which year is that?—Last year, during the rainy season. This chart shows the result of home treatment.

22,191. Have you any other chart which contrasts with that, showing other treatment?—Not a chart of sufficient contrast. I have two charts* of the Satara city and the taluka up to date.

22,192. (*Mr. Cumine.*) Had you any cases of plague amongst the Musalmans of the better classes in Bhiwandi?—No, hardly any at all.

22,193. Had there been many cases amongst the superior Musalmans, do you think there would have been a difficulty in effecting corpse inspection amongst them?—If there had been amongst the women, there would have been great difficulty, because they were zanana women—pardahnashin.

22,194. Do you think corpse inspection could have been carried out amongst them at all unless there had been Europeans present?—I do not think so.

22,195. Supposing you had the town of Bhiwandi to deal with over again, what measures would you, with your present experience, attempt to carry out?—I could not do otherwise than I did then if it was in the rainy season. In the dry season I should make every one of them go out.

22,196. And in the rainy season?—In the rainy season I should have to use force to make them go out. A large amount of accommodation would be required. Houses would have to be built upon piles, because it is a rice-growing country, and very wet.

22,197. It is not practicable?—It is not practicable; it is impossible.

22,198. What would you do?—I should, of necessity, have recourse to the same system.

22,199. Will the inhabitants of villages which have been infected once or twice do their best to keep infection out?—Yes; they will evacuate the place of their own accord. Now, even on the discovery of dead rats, some of the inhabitants of the villages under me do not wait for plague to break out, but evacuate the place at once—immediately on the discovery being made.

22,200. When they have evacuated do they abstain from re-visiting an infected house?—We cannot always keep them from revisiting the house—that is the difficulty.

22,201. Will they go back into the infected village site?—Yes.

22,202. They have not realised the danger of doing that?—No.

22,203. Will they isolate their own sick?—They will do that to a certain extent, but not enough. They will not keep sufficiently away from the sick.

22,204. Do they think that danger lies in the clothing of infected persons?—No; I think they believe in the poisoned atmosphere of the houses.

22,205. Do they believe in having their houses perchlorided?—They are very sceptical about its benefit. They believe in sunlight and air. They have very little objection to stripping the roofs off; they believe it does good.

22,206. Would they strip off the roofs of houses of their own accord?—I think they would now—all those who have had experience of plague.

22,207. Have you tried the kiln method of disinfection?—In one case only. Yesterday I had the floor of the Jailer's house dug up, preparatory to burning it.

22,208. You have no experience of it?—No; I am trying it now.

22,209. Have you noticed in this district a clear case of recrudescence of plague as opposed to re-infection from without, say from six to nine months afterwards?—Only in the way of a second epidemic the next year.

22,210. Are the villages which are being attacked this year the same that were attacked in the former epidemic, or are they for the most part a different set of villages?—They are a different set. That is the curious thing about this epidemic. This year it passed over most of the villages which were attacked last year, and *vice versâ*.

22,211. Have you noticed that even when it does get into a village which was badly infected in a former season it does not seem to spread much in that village?—No; I have not remarked that. During the first epidemic in the taluka there were 15 villages infected, with 192 cases and 149 deaths. During the second epidemic, which began in August 1898, there were 57 villages infected, and they are at present all evacuated. Up to that date we have had 2,560 cases, against 190 the year before; and many of those 15 villages which were infected last year have not been infected this year at all.

22,212. How many of those 15 villages have been infected this year?—I am sorry to say that I have not got the figures.

22,213. Are those villages so geographically situated that you would have expected them to be attacked this year?—Yes. I can give the instance of a village called Anewadi, which was very badly infected last year, and three other villages within a mile of it, Parbuchiwadi, Saygaon, and Kharshi. Those three villages are within a mile of Anewadi, and they are all very badly infected this year. There was not a single case in Anewadi until two days ago, when there was one solitary case, which, I think, was imported. Those three villages are very badly infected, and other villages which were uninfected last year have been badly infected this year.

22,214. Have you any idea whether the freedom of this village is due to the sharp look-out kept by the inhabitants?—To a great extent. I have found them turning people back of their own accord. They have barriers across the entrance to the village. It is one of the few instances in which they have really taken the initiative themselves, and taken an interest in it.

22,215. Do you think that the plague measures which are to be successful in the future must be worked with the co-operation of the villagers, and indeed by the villagers themselves?—I think we have to a very great extent to be dependent upon their co-operation, and the education they receive from the experience of plague induces them to take the initiative.

22,216. Which do you think is of the most educational value for the people, one European Staff Corps Officer endeavouring to look after 15 villages or his taking two small manageable ones thoroughly in hand personally?—I think it depends a great deal upon the man, whether his movements are active, and whether the villages are at a distance. For instance, the group of villages which I mentioned are almost within a mile of one another. It would not be enough work for him to look after those four villages. He could take a great many more than that, and visit them morning and evening.

22,217. (*The President.*) What are the huts of the rice cultivators like?—They are mud huts, with very heavy thatch. They are very badly ventilated, and there are no windows.

22,218. They stay in them only a very short time, is not that so?—Yes.

22,219. That is, relatively to other people?—Yes. They are very early risers. They rise before daylight.

22,220. In the case of villages which escaped infection this year, and were infected last year, was thorough disinfection carried out in the huts?—Those which were infected this year simply had strips of the roof taken off.

22,221. What was done with those which were infected last year?—Only the roofs stripped off. I was not here then. I believe that is all that was done.

22,222. Was there no chemical disinfection?—I do not hink so—not in the villages.

22,223. Has it been noticed whether rats have appeared in the villages which have become infected this year?—In a great many cases rats have appeared. The village of Umbowda Budruk is a good example of a village where the disease has attacked rats before it has attacked human beings. Rats were found in a house in the village on the 23rd of November 1898, and seven days after this discovery plague broke out in the house in which these rats were found. Six members of the family died of the disease. The village of Areh also, in the Parli valley, is another instance. On the 1st and 2nd of October dead rats were found in two houses, and on the 3rd of October plague broke out in both houses, and in those adjoining them. Nine people were seized on that date. I think those are good examples. I can give a great many others.

22,224. Have any dead rats been found in the houses which were infected last year, but which have escaped infection this year?—I could not tell you.

* Not printed with the Commission's Proceedings.

Lieut.-Col. H. Hay, I.C.S.

27 Feb. 1899.

22,225. Not to your knowledge?—Not to my knowledge.

22,226. (*Mr. Hewett.*) In those villages you mention in which dead rats were found, are you convinced that there had been no imported cases?—I am quite convinced. I made a searching inquiry.

22,227. How far off was the nearest infected village in each case?—The village of Parli was nearest—I should say within four miles.

22,228. Do you think rats would travel that distance?—It is quite possible. I have seen them go long distances.

22,229. That is how you would account for the infection?—It is quite possible they brought it from another village to Parli.

22,230. Was there any communication whatever from this village of Parli except by means of rats?—Yes, people go backwards and forwards continually—the same class of people.

22,231. (*The President.*) What is the nature of the water supply of the district we are considering?—All those villages on the banks of the Krishna get their water supply from that river, as a rule.

22,232. Those villages which have been chiefly affected are in the neighbourhood of the river, and are supplied by the river?—To a certain extent from the river.

22,233. How are those villages which are not near the river supplied with water?—By wells.

22,234. Taking the supply of the villages chiefly affected, it is from the river, is it not?—Yes, from the river.

22,235. And the water supply of the villages which have largely escaped is independent of the river?—Yes.

22,236. Is there any system of sewage disposal here?—No; it is all hand lifted into the carts, as far as I know.

22,237. What is done with it after that?—Then it is carted out, I do not know exactly where—trenched.

22,238. Is there any chance of the admission of sewage into this river?—There is no discharge of sewage into this river.

22,239. The only possibility is that an infected village might discharge part of its sewage into it?—Yes, perhaps so. There is a good deal of intercourse between the villages on this river.

22,240. Is there a also good deal of intercourse between the people living in the villages on the river banks and the people who are in villages removed from the river?—There is.

22,241. I believe there are a good many temples and bathing ghats on the river, are there not?—Yes.

(Witness withdrew.)

Capt. G. S. Thompson, I.M.S.

Capt. G. S. Thompson, I.M.S., called and examined.

22,242. (*The President.*) You are in the Indian Medical Service?—Yes.

22,243. Will you state your medical qualifications?—I am M.B., M., Ch., M.A.O., of the Royal University of Ireland.

22,244. In what places have your duties been in connection with plague, and of what kind have they been?—For about seven months I was in sole medical charge of the Parel Plague Hospital in Bombay, and since 31st July 1897 I have been on plague and other duty here.

22,245. You have, therefore, come in contact with a large number of plague cases, I presume?—Yes.

22,246. Have you inquired into the question of the infection of Bombay?—That came before us very often.

22,247. What was the result of your inquiry?—For many reasons, I came to the conclusion that most probably the infection was conveyed to Bombay from Hong Kong. My reasons for thinking so are as follows. As not every ship that left Bombay during the epidemic of plague since it broke out there carried away plague patients or plague infected rats, so it is probable that not every ship which left Hong Kong carried away infected rats. Possibly some particular ship may have cleared from Hong Kong to Bombay. I think the distance all through would cover the incubation period of plague, so it is not likely that a patient can have brought it from Hong Kong to Bombay.

22,248. You think it would be too distant?—Yes, without plague symptoms being developed on the voyage. Of course, there is the possibility of concealment and mistaken diagnosis. But the infection may have been brought by plague infected clothing, or by rats. In this connexion I refer to a number of ships which left Bombay, I think about ten only, on which plague had broken out, and only one barque which left Calcutta during the time Calcutta was infected. I think, therefore, plague rats brought plague into Bombay and landed at Mandvi, where grain is stored, and which is near to the docks, and thereby infected Bombay rats, which conveyed the infection to the houses of the people who afterwards became infected.

22,249. Mandvi was the district first infected?—It is considered to be the first place which was infected. At any rate, that is where plague cases were first noticed. The objections to that are, that intermediate ports, such as Singapore and Rangoon, were not infected before Bombay. My explanation of that is that they are not grain exporting ports, and of course, it is possible that the particular plague-infected ship which infected Bombay may not have called there, supposing it was only one, whereas Bombay for five months of the year does export grain. Therefore, there was an inducement when the plague-infected ship came to Bombay for the rats to land there, to forsake their dead, and try to seek new quarters.

22,250. You have considered the other possible sources of importation, I believe?—First, I may mention that it can hardly have been imported from one of the Himalayan villages by pilgrims. That possibility has been mentioned to you. The towns and villages which the pilgrims visited *en route* must be equally, if not more, insanitary, and as fitted to propagate the epidemic as Bombay, and the inhabitants must be equally susceptible to it, and yet they did not become infected. On the contrary, we find that plague spread from Bombay northwards towards those towns and villages. Then again, I know, as a matter of fact, that those pilgrims are particularly immune to plague by sleeping in well ventilated temples or in the open air.

22,251. What would be the shortest period of time in which a person might come from that district to Bombay?—These people would naturally travel on foot and take months.

22,252. We will take the shortest possible time. Suppose that some generous person were to pay their railway fares?—Perhaps they could do it in seven days, but I am open to correction upon that statement.

22,253. You think that it might be done within the incubation period of ten days?—It might be, but, as I have stated, it is not at all likely that these people would come by that means.

22,254. Have you considered how plague was imported into Satara?—It was introduced from the districts. The districts were affected probably in the month of July, especially about Karad. Before July 1897 there was a missionary on a visit there, and he reported to the then Collector that there were many deaths of suspicious fever, but steps were not taken until later on, in fact, not until two months after that was reported. I was not here at the time. The place at which plague was introduced, according to the official account, is, as the Collector, I think, mentioned, Mani Rajuri. It spread to the talukas, and then it was brought in definitely to Satara.

22,255. How many cases occurred in the first epidemic?—We had 719 attacks up to the end of February 1898. I can complete the figures up to the end of the first epidemic.

22,256. Will you complete the mortality also?—I have the table of both.

22,257. Can you give the numbers now?—Up to date there have been 1,160.

22,258. Can you give us the totals of the first and second epidemics separately?—I can do that, but I

have not the figures now. I consider the first epidemic ended on the 1st April, and then we had dropping cases in May and June. Afterwards, we began to have others in the rainy months, and then the second epidemic began. I can produce a statement. (The figures afterwards supplied by witness are as follows:—)

SATARA MUNICIPAL LIMITS.

First Epidemic, 873 cases; 727 deaths,
Second Epidemic, 287 cases; 209 deaths,
up to 31st March 1899.)

22,259. Can you tell us the total number of attacks during the first epidemic, and the case mortality?—The case mortality was about 66 per cent, I think.

22,260. When did the second epidemic commence?—We had one case on the 8th August, another on the 10th, and another on the 16th, and so on. The second epidemic really began about the 27th September 1898. It is rather curious that that is the same date on which the first epidemic began.

22,261. Were the cases which occurred in the interval imported cases, or cases which seemed to have originated here?—They were indigenous cases.

22,262. Were your means for preventing importation so perfect that you could be certain that there was no further importation?—We had a definite history of plague rats travelling in the direction in which the first cases occurred, and we had no history of importation. The patients first attacked certainly did not come from outside, and we had no history of persons visiting or sleeping in their houses. The roads were well guarded on all occasions. We had quarantine to keep out plague.

22,263. Have you observed any facts with regard to immunity from plague amongst human beings?—Amongst Europeans and Natives, I think, I have noticed it. In the last epidemic, although we had 45 adult Europeans, 20 European children, and 125 European soldiers, not one was attacked, although 20 Europeans and one lady nurse were daily engaged in plague operations. They remained completely immune. I should like to mention that Europeans now and at former times are not equally susceptible.

22,264. Will you state your views about that?—I can bring proof that in Surat in 1689 Europeans were not attacked; that is stated in Snow's Report,* and in Bombay we know they were reduced to almost one half. Regarding the comparative immunity of Europeans now and in the past, I am unable to prove that Europeans lived under the same sanitary conditions as regards ventilation (although from the Barracks Commission Enquiry, and the old Barracks, *e.g.*, in Bombay, now used as Commissariat godowns, we may infer that ventilation was not provided for in the past as now), but we do know from certain annexe to bungalows that the relations of Europeans with certain classes of natives was one of greater intimacy than happily prevail now-a-days. This may have led (as in Parel Hospital it undoubtedly did to three sepoy ward-orderlies being attacked) to Europeans falling victims in previous plague epidemics. My explanation is from the historical evidence in a well-known book, Moor's "Hindoo Pantheon."

"'In Bombay and Western India,' by James Douglas, vol. ii. p. 253. (Sampson, Low, Marston, & Co.), there is a footnote as follows:—

"Bombay: Change of Fashion (1810):—'This 'pleasant and salutary article (cow dung) is falling 'into disuse with the English, who, in their habitations 'and habits, are departing more and more from the 'sober dictates of nature, and the obedient usages of 'the natives.

"'We now, for instance, build lofty rooms, admitting 'insufferable glare and heat through long glazed windows fronting the sun, reflected by marble or polished 'floors; domestic comfort is sacrificed to exterior 'decoration.

"'No man of taste would now build a low sun-excluding verandah, nor mitigate the intensity of the heat 'by a cow-dung flooring. In Bombay the delectable light 'that, 20 or 30 years ago, was so commonly admitted 'through thin, semi-transparent panes, composed of 'oyster shells, is no longer known among the English 'except in the church; and these, perhaps, will, when 'the present worthy clergyman shall vacate his cure, 'give way to the superior transparency of glass. The 'church will then be like our new houses, insufferably 'hot, and the adaptation of punkahs . . . will be 'necessary.'"

In marked contrast to this, the houses of the first factors or settlers at Surat, as attested by the ruins of some, and the continued standing of others, were large, roomy, and well ventilated. Europeans at the beginning of this century everywhere in India may reasonably be supposed to have maintained the same standard of personal cleanliness.

Then we had no Eurasians, Native Christians, missionaries, or their families attacked, and there were 527 such in Satara city and cantonment. Thirdly, no Parsees were attacked. They comprised 50 souls. Of the hospital servants, ward boys, sweepers, corpse bearers, ayahs, &c., of whom there were from 60 to 65 in the first epidemic, only one was attacked, and that is mentioned because it can be clearly shown how he became attacked. Again, none of the jail population were attacked.

22,265. How many prisoners were there?—There were 198 prisoners. Then, again, the depôt sepoys, the 3rd Bombay Light Infantry, with their wives and families, remained immune; total 385. In the first epidemic the Sadr Bazar remained free.

22,266. That is a locality. You were speaking with regard to people?—Two other classes of people who, I think, remained practically free were the Buruds (cane workers), of whom there were 1,060, and the Dhangars (shepherds). The Buruds are said to be a dirty and degraded class, living in miserable huts and very poor, according to the Gazetteer. The Dhangars generally go out and attend their flocks during the epidemic months, and the Buruds lived in the outskirts of the village, and it is for that reason, I think, they were exempt, because they lived in the open air during the epidemic months. When we had the plague here they left the city. The sweeper caste are not so much affected as one would expect. On the theory that it is a filth disease, one would expect a great many more sweepers to be attacked. In Satara, during the first epidemic, we had 214 Brahmans attacked out of a Brahman population of 5,249. I quote from a table giving the plague attack by castes in Satara city from the first epidemic.

22,267. Did you ascertain the number of the members of each of these castes?—The Buruds in Satara number 203, and there are 186 wandering beggars actually living in Satara. They visited the town every day, and they come here twice a week for alms into the town—Tuesdays and Thursdays, I believe—and not one of them has been attacked; and I have frequently inquired into the matter.

22,268. Is there any other occupation which seems to affect the incidence?—No.

22,269. Will you kindly put your table in?—Yes, it is as follows:—

PLAGUE ATTACKS and DEATHS, by CASTES, in the SATARA CITY, 1897-98.

Castes, with English Equivalents.	Population.	Attacks.	Male Deaths.	Female Deaths.
Brahmans	5,249	214	102	81
Mahrattas	6,048	232	96	86
Musalmans	2,789	64	31	25
Mangs, night-soil labourers	656	6	3	2
Dhers, tanners	408	4	1	0
Malis, gardeners	589	17	8	6
Rajputs	25	19	2	6
Janjams, worshippers	05	2	0	
Banniahs, money-lenders	437	18	8	7
Goldsmiths	621	5	2	3
Shoemakers	440	3	1	2
Gujars, money-lenders	333	24	11	6
Washermen	126	4	3	1
Tailors	1,772	31	10	15
Kasars, brassfounders	527	11	5	6
Butchers	18	2	1	1

* *See* p. 66 of "Report on the Outbreak of Bubonic Plague in Bombay, 1896-7," by P. C. H. Snow, I.C.S.

Capt. G. S. Thompson, I.M.S.

27 Feb. 1899.

PLAGUE ATTACKS and DEATHS, by CASTES, &c.—*cont.*

Castes, with English Equivalent.	Population.	Attacks.	Male Deaths.	Female Deaths.
Marwaris, money-lenders	321	5	2	3
Barbers	444	14	4	8
Mahars, night-soil labourers	525	6	4	0
Shepherds	104	4	0	2
Sangars, blanket sellers	221	11	4	5
Telis, oil pressers	527	11	7	3
Karanjkirs, saddlers	45	7	4	3
Tinmen	57	9	0	0
Parbhu, Gujarati Brahman	113	4	2	2
Tambolis, betel-leaf seller	62	3	1	2
Carpenters	212	6	2	4
Banjaris, grain traders	197	6	0	1
Mehtars, sweepers	140	9	6	1
Alari, metal moulders	43	1	0	1
Christians	57	1	0	0
Pedlars	11	1	1	0
Blacksmiths	84	1	0	1
Gosain, beggars	128	—	3	1
Masans	60	—	1	1
Jewellers	13	—	1	0
Lonari, coal merchants and burners.	210	—	0	1
Coppersmiths	57	—	6	3
Fishermen	367	—	2	2
Lakheri, bangle seller	40	—	1	1
Hymn singers	71	—	1	0
Palwegars, silk-workers	—	—	5	3
Shenni, fish-eating Brahman	—	—	1	0
Weavers	149	—	1	2
Potters	172	—	1	2
Totals	—	—	344	300

The under-noted castes furnished no plague cases:—

Castes.	Population.
Parsee	63
Jews	15
Buruds, basket-makers	203
European Christians	155
Goanese	70
Gaolis, milkmen	126
Europeans	102
Madrasis	13
Arabs	17
Eurasians	36
Naikinis, prostitutes	33
Bairagis, wandering beggars	186
Total	1,018

22,270. You spoke about immunity with regard to locality?—I refer to Bombay. The Halalkhors and the people who live on ships have been particularly immune. That I can account for, according to my theory.

22,271. What about the Halalkhor class?—They are a sturdy class, and live in municipally constructed huts or houses, which are better ventilated. Dr. Weir has referred to that.

22,272. With regard to ships?—Of course, they are well ventilated too.

22,273. Have you anything to say about localities?—Last year the Sadr Bazar here, only a mile distant from the plague-stricken city, remained immune, with a population of 2,335. There was constant communication between the city and the Sadr Bazar. The reason for that was the fighting ahead of plague in those places; the houses were unroofed in strips, to let in sun and air, and, therefore, they were well ventilated. That was not done this year, and the Sadr Bazar has had an epidemic. There was no fighting ahead of plague this year, although I advised it as regards the Sadr Bazar, and they had a severe epidemic about six weeks afterwards.

22,274. Can you give us any explanation which would cover all these cases of immunity?—It depends on the habits of the people. Referring to the castes, it depends on the condition of ventilation of the houses and the habits of the people as regards their knowledge of the necessity for fresh air and cleanliness in and about their houses. Of course, the districts which were exempt lost year were compulsorily ventilated by unroofing the houses by strips at a time, and holes being knocked into the walls before plague came.

22,275. What have you to say with regard to cleanliness?—I do not say that filth has nothing to do with the causation of plague, because we know that filth spoils the air and makes it unfresh equally with deficiency of fresh air, overcrowding, or bad ventilation.

22,276. You think that the explanation common to the several instances of special liability to plague is to be found in impurity of the air?—Yes.

22,277. And conversely, that the relative purity of the air explains the instances of impunity from plague which you have mentioned?—Yes.

22,278. Have you any views to advance with regard to the diffusion of plague?—I think it is chiefly spread by human agency, including under that term infected clothing and bedding. I think, also, it is spread by animals to which the germ is pathogenic — rats, squirrels, and, to a lesser extent, monkeys.

22,279. Have you any clear cases in which the clothing appeared to be the medium of conveyance?—As regards Satara I have not a specific instance to give.

22,280. Have you any instance elsewhere?—I think not, except, historically, from the literature of plague.

22,281. Can you give us an instance in which rats conveyed plague?—I think rats conveyed the plague to Satara city from the first infected places here this year. Before the plague began in the city, I used to get 20 rats in a week to examine from the houses in the city next to the Post Office and next to the infected suburbs. I examined these by bacteriological examination and *post-mortem*, and found invariably that they had died of, or were subject to, plague.

22,282. What did you find in the *post-mortem* examination?—Slightly inflamed glands in the inner side of the thigh, and enlarged spleen. Those are the signs we used to go on in Bombay. That was confirmed by cultures.

22,283. What did your bacteriological examination include?—Growth on agar.

22,284. And the ordinary morphological characteristics, I suppose?—Yes; I had no means of going into it thoroughly with a microscope. We had not an oil-immersion lens.

22,285. Therefore, you trusted chiefly to cultures?—Yes; the characteristic culture on agar.

22,286. I think you have some evidence to give with regard to the possibility of animals in a lower biological scale being infected?—I made *post-mortems* with the cultures on squirrels and also on leeches which had been applied to plague buboes before they had suppurated, and I have made what I thought characteristic growths that I got from those leeches afterwards. I made a *post-mortem* on two monkeys, only one of which suffered from plague; the other had not died of plague.

22,287. You did not do anything more with regard to leeches beyond making cultures?—I had no means of doing anything else. I wrote to Dr. James and he could not account for a village, a great distance outside the cordon, being infected by plague, and I suggested that perhaps the leeches used in the plague infected camps were taken outside the cordon and used for other diseases. He inquired into the matter and said that he had strong reason to believe that that was the cause of the villages at a great distance becoming infected.

22,288. What measures have you found most effective in dealing with plague in Satara?—Evacuation is the first and most important to be carried out quickly and effectually. But one must have an idea of what it means. The word is in everybody's mouth. The reason, I think, it is successful is, that first it removes the people from their infected houses and thereby diminishes overcrowding, and if they are put into Government constructed huts, or huts which are

properly constructed, they get into fresh air, which neutralises the plague. Only under those circumstances will the measures be successful.

22,289. You wish to point out that the mere fact of evacuation is not sufficient, but there must be certain things attended to in that evacuation; what do you think is the most important?—That the Government huts should be ready for the whole population of the area to be evacuated. It is useless removing them from structurally insanitary houses to huts equally air-tight, because that would defeat the benefit of evacuation almost entirely.

22,290. Is that the result of your experience?—It is from my experience of Satara, and some villages which I know continued to have plague after evacuation.

22,291. Can you narrate your experience?—The town of Limb was completely evacuated, and yet plague continued for months afterwards, because the people were allowed to hut themselves in an area of 5 miles round the village, and they did not go into Government constructed huts. They continued to have plague for months after evacuation. Plague lasted eight weeks before evacuation with 45 deaths, and 22 weeks after with 521 deaths.

22,292. How do you account for that?—Because they went into badly ventilated huts.

22,293. What were the characteristics of these huts which produced the bad ventilation?—First of all their structure. They were made of bamboo poles, and they used matting for the walls, while the roof was constructed of grass. We leave air spaces on the top, but if the people are allowed to build their own huts they will build them of karbi, and daub them inside and outside, and make them as air-tight as possible, with very small openings, and they will also overcrowd them.

22,294. That was the condition of the huts in the instance which you have given?—Yes, of those huts in which plague continued to occur. I only visited those places occasionally, and had not many opportunities of verifying these facts. There were other huts constructed as the Collector described, with only a few stalks of this karbi and those remained free from plague so far as I can remember.

22,295. Have you any definite instance in which the evacuated people continued to have plague among them where that continuation was, in your opinion, due to want of ventilation in the huts they occupied?—The town of Rahmatpur, of 6,670 inhabitants, had plague for 15 weeks after complete evacuation owing to the insanitary huts to which they went. Before evacuation plague had lasted seven weeks, and there were 106 deaths before, and 162 deaths after evacuation.

22,296. Will you describe those huts?—They have the same characteristics as those of Limb which I have described. I have seen them.

22,297. Have you any experience of partial evacuation?—We had only partial evacuation of a large town like Satara, and yet plague continued to spread to non-evacuated districts.

22,298. Was that partial evacuation accompanied by disinfection?—Case disinfection only, that is to say, we disinfected the houses in which plague cases had occurred, as soon as possible after a case of plague was reported.

22,299. Were the cases of plague removed?—Yes. Isolation and segregation were carried on at the same time.

22,300. Within what time were the plague houses disinfected after the removal of the patients?—In the beginning the houses were disinfected the same day or the next day, but as the number of cases increased the work, fell greatly behind; we could not get coolies here.

22,301. Partial evacuation with disinfection failed to stop the progress of plague?—Yes.

22,302. What do you mean by disinfection?—Chemical disinfection was used on this occasion.

22,303. Were there no instances in which disinfection was carried out by sunlight?—I tried to get the Collector to allow me to have that done, but he insisted, according to the order of the Plague Commissioner, that chemical disinfection must be carried out in every house in which a plague case had occurred.

22,304. To the exclusion of every other form of disinfection?—Both measures were adopted.

22,305. You opened up the roof as well as applied chemical disinfectants?—Yes.

22,306. What was the chemical disinfectant you used?—A prepared solution of perchloride of mercury, one in 1,000.

22,307. Who is responsible for the preparation?—At first we had men who came from another district who had had experience in this matter. They were natives. Then about the month of February we had a European who came from Karad, and he superintended the mixing of it under my supervision.

22,308. Will you tell me exactly what was done?—First, a solution of perchloride of mercury dissolved in water, with ammonium chloride, was made up and stored in stone jars and corked, and from those a certain measure was taken and added to a kerosine-oil-tin full of water, and that made up a strength of one in 1,000.

22,309. It was stored in those jars until the perchloride of mercury had been entirely dissolved?—Yes. It was made at night in order to be used the next day—a strong solution.

22,310. Are you certain that the perchloride of mercury had been dissolved?—Yes.

22,311. How do you know?—Because I emptied out the contents of the jar the next morning in the first few instances, to see if it had really been dissolved.

22,312. It was an opaque jar, was it not?—Yes, but we emptied it into a vessel so that we could see it.

22,313. And anything solid would be removed from the jar, you think?—Yes.

22,314. Will you describe the process?—We have a certain measure of water, we put it into the jar, and then added chloride of ammonium to it, and then perchloride of mercury in the proper proportion.

22,315. In what form was the perchloride of mercury?—Solid.

22,316. Was it in crystals or powder?—Powder.

22,317. Was the jar shaken?—It was mixed up with a wooden stick with a glass tied to the end of it.

22,318. So that you made certain it was all dissolved?—As far as we could possibly do so.

22,319. There could be no doubt about it?—I should think not. A certain glass measure of that was added to one kerosine oil-tin full of water, and that made it one in 1,000.

22,320. How was this solution of one in 1,000 applied?—We had a supply of wooden pumps and tubs, which were supposed always to be the only things used in applying it. But when the pressure came we had to resort to brass pumps.

22,321. You pumped it with considerable force?—Yes.

22,322. Where?—On the wall, roof, ceilings, and especially the floor. I laid great emphasis on that, that the floor was to be done more carefully than anything else.

22,323. Nothing else was added to this solution?—Very often the coolies did defeat my object, because they put the pump on the ground and then took it up covered with mud, and then put it in. I had, at last, to tie the pump to the tub; in fact, I took every precaution, although I did not believe in disinfection, to give it every chance in a practical way, and I recommended the re-disinfection of plague houses.

22,324. When you discovered this possible source of error you had it corrected as far as possible?—Yes.

22,325. Why do you not believe in disinfection?—Because although experiments in laboratories will kill the plague germ, I was doubtful, from the practical experience I had had, that it would kill the germ under the natural conditions in which we found it in native houses mixed with cow dung floors and so on, and further experiments in Haffkine's and Hankin's laboratories have fully confirmed that view.

22,326. At present, you do not believe in chemical disinfection for plague?—I do not say it is of no use, but it is unreliable.

22,327. It is not a certain measure?—It is not to be relied upon at all. There are better disinfectants, such as sunlight and fresh air, which are more cheaply available.

Capt. G. S. Thompson, I.M.S.

27 Feb. 1899.

22,328. Have you anything further to say with regard to chemical disinfection?—Experiment's from Haffkine's and Hankin's laboratories are before you, and I have nothing more to say except from practical experience. I have some cases in which plague occurred in houses in Satara which were disinfected, and I can put a statement of them in. I have also some cases which occurred outside what is considered the ordinary incubation period of plague, that is to say, more than 10 days.

22,329. Does that deal with chemical disinfection?—The houses were disinfected and the people were allowed to go back, and 15 or more days afterwards plague cases occurred in the same house.

22,330. Of course, you eliminated all other sources of infection?—Yes, the cases are given in the following table:—

Some Instances of Plague in Disinfected Houses.

Name.	Pet.	Date of Disinfection.	Date of Attack.	Days after Chemical Disinfection.
N. M. Bhosale -	Somwar -	15.2.98	22.2.98	7
P. Kodha -	„ - -	15.2.98	21.2.98	6
K. K. Maruti -	Yadagopal -	18.2.98	23.2.98	5
A. K. Krishnaji -	Pratapganj -	20.2.98	25.2.98	5
S. R. Lawzekar -	„ -	12.2.98	26.2.98	14
S. K. Sitaram -	„ -	21.2.98	3.3.98	10
P. K. Gulabsing -	„ -	21.2.98	16.3.98	23
B. W. Subhana -	Durga -	27.2.98	26.3.98	27
D. N. Jagatap -	Mangalwar	15.2.98	8.3.98	20
G. Rupachaud -	„ -	23.1.98	27.2.98	35

The Jailer's house was disinfected by one in 1,000 solution of perchloride of mercury, ceiling, walls, and floors, including the verandahs, front and back, on 18th and 19th January 1899, once; and again on 31st January 1899; yet the Jailer and his wife were attacked by fatal plague on 14th February 1899. This house had been disinfected in 1897, in the month of December, by mercuric perchloride solution, so that the effect of that disinfection was not permanent, although it appeared to be effectual, and by some was credited with stopping further attacks there, as three plague attacks took place in this house in the 1898-99 epidemic. The house was disinfected in the presence of the Chief Plague Authority in January 1899, and the floors twice, the second time with fresh perchloride solution.

22,331. What are the clinical varieties of plague which you have encountered?—I divide them (in addition to primary plague pneumonia or malignant plague) into cerebral, or nervous, and that, has two sub-varieties, quick and slow. I mean by "quick" that it kills a person in a few hours or a day, and by "slow" that the patient lingers on for perhaps three or five days, or recovers. Secondly, there is the septicæmic form, which is also quick and slow as regards its progress. In both these the infection, I think, goes into the blood.

22,332. Why do you think so?—It is only theoretical. We have a supposition of how these diseases had affected people, and we try to account for the fact that they kill people quicker than others.

22,333. By what kind of reasoning have you arrived at your opinion?—From these two diseases occurring without any previous symptoms, and affecting people quite suddenly and killing them off very quickly indeed.

22,334. You mean the rapid development of the disease?—Yes.

22,335. Are there any other forms?—Thirdly, there is the ordinary mild bubonic form, which probably infects through the lymphatics. Then there is a fourth variety which we have identified, which is very rare; that is the abdominal or typhoid, which is also quick and slow.

22,336. Why do you think the third variety is caused by conveyance through the lymphatics especially?—That is a generally held opinion, but I myself have objections to its being conveyed through the lymphatics, because I think the most common method of infection of plague is through the air, although I cannot deny that plague may be conveyed through inoculation from the lymphatic channel, and rarely by cuts and abrasions in the extremities of natives. I have had instances of that.

22,337. Your opinion is not very strong on that?—I think that is the rarest form of infection.

22,338. What is the evidence of the existence of the abdominal or typhoid form?—I have had some cases among the Natives here. Altogether, I have seen one European case infected, and three Natives out of about 750 cases of which I have clinical notes.

22,339. What are the distinguishing clinical features of this form?—General typhoid symptoms and slow development of the buboes. A case is fully reported in the first epidemic. In General Gatacre's Report* I have recorded one case in full, and I have notes of others which I have seen here.

22,340. Could you state what you think are the characteristic features?—The details of this case are confirmed by the other cases which I have seen here of plague, simulating enteric fever. The patient was attacked with giddiness, trembling, chilliness, headache, repeated vomiting of bilious matter, and prostration. This continued for a few days. Then there was diarrhœa of a thin, yellowish, watery, fœtid character, six motions in 24 hours, with griping and gurgling; he was delirious, with an elevated temperature, of course. There was repeated vomiting, and nausea was constantly present. The tongue had a yellowish-brown fur with moist tip and edges clean, the skin hot and clammy, bad odour from the breath, peculiar earthly smell from the bedclothes when turned down. There was a headache and drowsiness. The patient wanted to sleep but could not. The eyes were injected.

22,341. There is nothing there, except diarrhœa, which is distinctive, is there?—The general appearance of the typhoid state, that is to say, that the patient waved his arms aimlessly before his face, sinking down in the bed and fumbling and picking at the bedclothes, with enteric motions which were acid to reaction. There were no typhoid spots, although they were looked for.

22,342. To bring it into a group of plague cases there appears to be nothing but diarrhœa?—And the typhoid symptoms.

22,343. Typhoid symptoms in as far as there are some nervous symptoms?—Yes.

22,344. Have you seen any pneumonic cases?—I have seen 19 cases of primary pneumonic plague, and only one recovery. I wish to mention the importance of marking thoroughly the difference between that and the other varieties of plague.

22,345. What are the distinctive symptoms of plague pneumonia as distinguished from ordinary pneumonia?—A very small area of the lung is affected, as is shown by clinical examination, and the sputum is frothy and bloody, and in culture contains myriads of plague bacilli. It is the malignant form of plague.

22,346. How is it a malignant form?—From comparing it with small-pox, where we have discrete and confluent, and so on.

22,347. Have you found the pneumo-coccus of pneumonia in the sputum?—The German Commission worked out this in Parel, but did not find it.

22,348. Have you made any examination?—No, I have no microscopes.

22,349. Have you seen any very mild cases of plague?—In Parel one very mild case I saw in which the patient was all right in three days and attended to his work. He was a sweeper in the Parel Hospital. I have not seen any here.

22,350. Was any bacteriological examination made?—Yes.

22,351. Have you seen any cases of enlarged glands, which in some respects simulate plague, and could not from the symptons be distinguished from plague?—In Bombay some cases during the first epidemic were sent in as plague which I was able to prove by bacteriological examination were not plague, although they had enlarged glands.

22,352. Do you think that proof can be obtained only by bacteriological examination?—Now, I am of that opinion.

* *Vide* pp. 86–7 of "Report on the Bubonic Plague in Bombay 1896–97," by Brigadier-General W. F. Gatacre, C.B., D.S.O., Chairman, Plague Committee.

22,353. You think there is a disease involving the lymphatic glands, sometimes also accompanied with high temperature, which is indistinguishable from plague except by bacteriological examination? — Quite so.

22,354. Have you any evidence as to the incubation period of this disease?—We take the incubation period from the first case we see generally, and count from that, but it is obvious that patients who have subsequently developed plague have been equally exposed in the plague-infected house as the first patient. Counting in that way we generally find that the attacks develop within ten days, but I have some examples in which it went beyond that period.

22,355. With regard to the etiology, do you think there is any relationship with such circumstances as famine, rainfall or subsoil water?—As regards war and famine, these visitations drive the people into the towns and they overcrowd the towns, and then, if plague happens to come along, naturally the overcrowded town will be more subject to attack.

22,356. Have you any facts with regard to rainfall?—No; I do not believe there is much relation between the two except that the life of the germ outside the human body seems to have something to do with the state of the moisture of the ground. It is in a hybernating condition during the rain, and after the rain it becomes virulent, and becomes able to attack people. The idea is that it is always in the soil, and is alive in the soil, and in rats and other animals outside the human body, and thus the epidemic is continued after perhaps a few dropping cases, and then, subsequently, next year, when the weather conditions are favourable, and when the people go into the ill-ventilated houses, the plague is able to attack them, as we found in Satara.

22,357. Why do you think it occurs so much in seaport towns and large towns?—That is natural, because we know that cities have been built for the sake of commerce on the banks of the river and that these are the emporiums for import and export into which plague will naturally be brought first by communication with other infected places.

22,358. How do you think the virus actually enters the body?—Principally through the air, although I cannot deny that there are other methods by which it may enter.

22,359. You mean, it is inhaled into the lungs?—Yes; that is the most common method, I think.

22,360. Why do you say that?—From the absence of evidence of other means of infection, except in very exceptional instances. One other possible means mentioned is inoculation through cuts and wounds in the extremities, but very few cases confirmatory of that have been found, and in some of those I have been able to recover the plague bacillus from a blister raised on the opposite limb, showing that it was a case of generalised septicæmia, and that this was really an instance of black blister, of which I have seen five or six examples here.

22,361. It did not, in your opinion, indicate the entrance point at all?—Not at all. Besides that, I have many reasons against that theory, and my objections are stated together as follows:—

1. The inoculation theory cannot explain the fact, that fever and general symptoms precede the appearance of the local expression of the lesion of infection, if such exist, and this is the sequence in all the cases of plague that I have seen.

2. In those cases where plague bacilli had been isolated from the supposed initial lesion I was able, at the same time, to demonstrate the presence of plague bacilli in the serum of a blister raised upon the opposite limb; proving that the patients had plague bacilli generalized in their blood, and were, in fact, suffering from septicæmic plague, plague with black blister. All those patients died, which is confirmatory of this view.

3. On this theory of cutaneous infection the occurrence of buboes in sequence, with intervals, and in sites in no way anatomically related with the first bubo or site of supposed inoculation cannot be explained satisfactorily.

4. Whole families are attacked simultaneously or within ten days or so of each other, and it is difficult to believe that all of them should exhibit cutaneous lesions sufficient for inoculation at or about the same time.

5. The rarity of such lesions, although carefully looked for, is an important objection to this view. At Parel Hospital only five such instances were discovered amongst 304 patients, and many medical officers studying plague there were daily examining patients to discover evidence of this mode of infection; and the medical subordinates were instructed to critically examine all admissions for slight wounds, &c., below the affected lymph gland. In the Satara hospitals such lesions were even rarer than at Parel.

6. "*a.* It is difficult to believe that any large proportion of the inhabitants habitually have lesions of the skin—even though minute ones suffice—suitable for the absorption of the infection.

"*b.* We know that in septicæmias and other external infections, a decided lesion is required, and that, even though this be present, infection does not always occur. It seems very improbable that, in any large proportion of those having the smallest lesions, it would chance that those should become infected.

"*c.* Were inoculation by very slight cutaneous lesions the usual mode of infection, the plague would be even more destructive than it is.

"*d.* When once established in a place, the disease has spread more rapidly than if it were diffused mainly by external inoculation.

"*e.* The rarity of the occurrence of plague among those of the upper classes of natives who live in houses of a superior class, and who do not ordinarily frequent insanitary places, yet whose habits as regards the infrequent use of shoes, and in certain other ways, resemble those of the poorer classes.

"*f.* Women's duties as attendants on the sick must have exposed them to the dangers of cutaneous inoculation far more than the men; yet they were (and generally are) attacked in nearly equal numbers. For, of those attacked in Karachi between the ages of 20 and 55, one in every 21·5 of the population were men, and one in every 23·5 were women. Presuming external inoculation to be the rule, it, therefore, appears that it is not more frequent among women who tend and handle those sick with plague, than among men who do less of those duties, which is scarcely credible.

"*g.* The still greater infrequency of inoculation among the staff and attendants in a Plague Hospital; were external inoculation the common mode of infection, it would be reasonable to think that, in Indian hospitals at least, the paid attendants, and even more commonly, the relatives of patients, would, owing to their ingrained disregard of precautions, have frequently succumbed. This immunity appears to prove the truth of aërial infection and to seriously weaken any evidence that exists in favour of internal inoculation. For whilst the conditions favouring the one are, in a hospital, very greatly diminished, those conducing to the other continue to exist for all alike with but slightly diminished strength.

"*h.* The occurrence of infection by way of the lungs is acknowledged by the supporters of external inoculation; and the possibility of the former being granted, it seems somewhat unreasonable, looking at the greater facility with which it would occur, to question its universality. It may be conceded that pulmonary inoculation does cause, in certain instances, a special type of the disease, the chief feature of which is primary pneumonia. But it would seem that it has yet to be proved that the ordinary form of the disease is not commonly conveyed through the lungs. That a general affection of the lymphatic glands cannot result from pulmonary infection does not seem probable.

"*i.* The analogies of other contagions do not seem to favour the external inoculation theory. In none of the other specific fevers does this, normally, occur; whereas in those diseases in which it is possible or usual, local manifestations of infection are the rule (tubercle, leprosy, syphilis, septicæmia, anthrax, diphtheria), or they are entirely absent (tetanus, hydrophobia). But, in their general character, the infections above-named differ entirely from those eruptive fevers (typhus, relapsing fever, mumps) which plague most resembles; and there is no reason to believe that, in any of the latter, infection takes place by external inoculation. In mumps one special gland becomes inflamed, yet it can scarcely be argued that this is due to external inoculation. Why, in a similar manner, should not the whole lymphatic system be affected in plague through pulmonary inoculation?

Capt. G. S. Thompson, I.M.S.

27 Feb. 1899.

"*j*. The rapidity with which plague spreads among families, and among occupants of the same dwelling, seems to support causation by aërial infection. Were external inoculation the usual mode of infection, it seems very improbable that the coincidence of the time of exposure of cutaneous lesions to infection would occur in so large a proportion of cases. Whereas these are easily explained by the theory of pulmonary infection, to which all those inhaling plague-poisoned air are exposed from the first moment of its inspiration.

"*k*. Though cutaneous inoculation may occasionally happen, its general occurrence would seem improbable." The arguments 6(*a*) to (*k*) are quoted from a report* by Surgeon-General Bainbridge.

Professor Aoyoma, in Hong Kong, inoculated himself accidentally and died of plague, and Dr. Stricker, in Bombay, during a *post-mortem* examination, cut his finger and got a mild attack of plague from which he recovered. Animals are easily inoculated with plague. Surgeon Wilm, in reference to the Hong Kong epidemic of 1894, relates that "About 300 Europeans "were employed in disinfecting operations and all "wore boots and putties, yet the few who were affected "all had enlarged glands in the groin. It is extremely "unlikely with such precautions that they had cuts, "&c., on their feet and legs, but they must frequently "have had cuts, &c., on their hands and came in "contact with infected articles; yet none developed a "bubo in the armpit. This shows that direct inocula-"tion through cuts or abrasions was not, and is not, the "usual mode of infection. Infection may take place "by the lungs, or alimentary canal, but aërial "infection is, in my opinion, the most common."

22,362. Do you know of any experiment showing the results of introducing plague virus into the respiratory passages?—There are experiments by the two Russian observers, of the first Imperial Russian Commission, on monkeys: they found they could give plague pneumonia to susceptible monkeys very easily by spraying the solution of the virus in the air in the cage in which they lived.

22,363. Judging from these experiments, would you not expect plague pneumonia to be more frequent than it is, as you think the virus is principally introduced through the air?—There is the possibility to be considered that it may pass the lungs and produce an infection of the lymphatic glands, the ordinary septicæmic or bubonic form, or cerebral varieties even, without specially infecting the lungs, which we would recognise clinically.

22,364. This is very hypothetical?—Yes.

22,365. Have you any opinion as to whether the virus may be absorbed from the alimentary canal?—No; that is a supposition also from the so-called abdominal cases. The natives have a habit of eating food off the ground; of course, their nails are not always clean; the sputum of the patients, especially in pneumonic cases, would infect the ground from which they eat their food.

22,366. That is a possibility, but have you any observed facts?—No, I have no cases to prove it.

22,367. How do you think the virus proceeds out of the body?—Only by those excreta which will contain blood at any time. I have evidence to show that it cannot be excreted by the fæces or urine, unless they contain blood. The German Commission and myself examined all excreta, tears, and everything else, to find the germ, and failed to do so, except in cases where the excreta also contained blood and the sputum.

22,368. Did you find it in the urine?—We never found the germ in the urine unless there was blood also.

22,369. Was that hæmaturia or hæmaglobinuria?—Hæmaturia.

22,370. And the fæcal matter?—Never when it did not also contain blood; in fact, it was extremely rare; I never saw a case in Parel.

22,371. You think, therefore, the virus can only be passed out of the body through an actual lesion of some surface?—So I believe, or from the sputum of a plague pneumonic case, which, I think, is the most important means by which plague infection is given off by the patient.

22,372. Have you any experience with regard to the treatment of plague which you wish to state?—Only the antiseptic treatment, which I introduced. Perchloride of mercury was tried in very large doses, and seemed, along with stimulants and ordinary treatment, like nursing, dieting, and keeping the patient lying down, to give better results than any other treatment I have tried.

22,373. Can you state that in a statistical form?—From a report regarding the Parel Hospital, which I have completed up to that date, and from evidence which I have procured since, I shall go into that question fully. In my précis I ask permission to put in the full statistics. These I have excluded at present, because I thought I had enough evidence on other points.

22,374. Your experience is in favour of antiseptic treatment, I understand?—Yes, combined with stimulants and ordinary nursing.

22,375. Aiming at the source of the illness—the actual cause—I suppose, you mean?—Yes.

22,376. And cardiac feebleness you treat at the same time with cardiac stimulants?—Yes, quite so.

22,377. What are the plague measures which you consider effectual?—Looking at it from a broad view, the only measure which would be effectual is an alteration in the habits of the people from the etiological standpoint and historical standpoint, and from my experience, I believe that plague is a want of fresh air disease, and that it can be very easily destroyed by fresh air. In that way it is in marked contradistinction to typhus fever. No matter what you do with regard to sanitary houses, like Lord Sandhurst's improvement scheme, if the people do not understand the precautions which have to be taken they will defeat your measures. They will not get fresh air at night, and they will continue to do those things which will tend to continue plague.

22,378. Of course, in a big house, even if the means of ventilation were far from perfect, so long as the house was not overcrowded, the air would remain pure for a long time?—Yes.

22,379. Have you any other measures to mention which you consider useful?—Yes, as temporary expedients. I call all those measures which we have adopted, namely, evacuation, which is a strong measure, and isolation, temporary expedients.

22,380. Evacuation you have already discussed as a means of securing fresh air?—Yes, and that is the ground upon which it is useful. Isolation of the sick naturally comes in, and segregation of contacts in health camps, and disinfection by the real disinfectants, viz., fresh air and sunlight. Of course there are other disinfectants—not chemical—viz., steam and boiling water. Then quarantine comes in to keep plague out.

22,381. You have already expressed an opinion that disinfection by chemical agencies is not a very effective measure in itself?—Quite so. I do not condemn it entirely.

22,382. Have you some illustrations in favour of your view—that fresh air is the most important thing?—I have mentioned the facts in my evidence in connection with instances of immunity. Then there are those which I have already stated with regard to castes, people, and localities, and also from the failure of evacuation and facts regarding the floating population everywhere, not only in Bombay, but also in Canton. Clifford Allbutt's book mentions 250,000 people living on the river. Then I have particular instances. For instance, Commander G. S. Hewett (March 5th, 1898) has forwarded to the Press the following remarks with regard to the Tardeo section to the Secretary to the Bombay Plague Committee: "An extraordinary outbreak of "plague took place in chawl No. 202, Bapty road, on "the night of 2nd instant. At 11 p.m. there was no "sick in the house, and at 4 a.m. on the 3rd (the day "following) there were four deaths, and at 10 a.m. "seven other cases were removed to hospitals. On the "morning of the 4th instant nine more cases were "removed to hospitals, making a total of 20 cases in "24 hours. This remarkable outbreak appears to have "been caused by the extreme cold of the night of the "3rd instant, which caused people to *close all the rooms* "inhabited. The chawl, which is in a fairly sanitary "condition, is situate in an open compound, *with* "*plenty of light and air*, and no cases of plague had "occurred in it." That was quoted against me as

* "Report on the Plague in Sind, 1896–97," by the Principal Medical Officer, Sind District—not reprinted in the Proceedings of the Commission.

showing that plague could not occur in a well-ventilated shawl, but the reason is plain. The people shut all the doors and windows on account of the high wind, and immediately in one night they got 20 cases, although for two years previously, although they were surrounded with plague, they remained plague-proof.

22,383. Do you know that during the two years in which they were plague-proof they did not on any occasions shut the doors and windows?—With regard to that, I have no information.

22,384. Have you any other examples?—The Jailer's house is a well-ventilated house. The Jailer's house is an ideally perfect house, even for Europeans to live in, but as he only used the centre room, which may be 14 feet by 12 feet, for himself, his wife, his mother-in-law, and six children, who all sleep on the floor, and in the cold weather they have a charcoal brazier in the centre of the floor, and cover their heads with razais, blankets, and so on, and as all the doors and windows are shut, they have made this naturally well-ventilated house perfectly insanitary, and constantly there was plague last year, and there was also plague this year. The jail, which is next door to it, remained free, although there were plague rats in it, and this year a plague case was introduced into the jail, and there were no further cases, because ventilation is enforced there at night on the prisoners.

22,385. Did not the lesson gained on the first occurrence of plague prevent a continuance of this habit of closing all ventilation openings?—No; the Jailer would not be convinced, although his daughter was attacked. I diagnosed the case on the 17th January this year before I got ill, and I said, "Now, surely, you will give up your bad habits and preserve your health?" And he replied: "God will take care of my health."

22,386. You have had some experience of Yersin's curative serum, I think?—The total number of cases inoculated by me, or by Yersin, was 27. He injected the first three, and I injected the other 24, in Parel Hospital. Of the 25 cases of undoubted plague, 13 died and 5 recovered, the percentage of mortality being 76·5.

22,387. How does that contrast with the mortality of cases not treated?—The general mortality in Parel was 64·5 per cent., but 66 were moribund on admission and 17 died during the first day in hospital and 38 during the second day. If those cases are excluded, the mortality was 41 with cases treated; but then we must further exclude Yersin's cases, and then the rate of mortality under hospital treatment, separate from serum treatment, was 30·8 per cent. of the admissions who lived after 28 hours in hospital and actually got some hospital treatment.

22,388. This serum was not applied to cases obviously moribund, I suppose?—No; in fact, at the end, Yersin advised me to make selections of cases which had been ill under 24 hours. Even then, the mortality amongst those was, if anything, worse.

22,389. Have you had experience of Lustig's serum?—No, I have not used it myself. We tried it on animals in Hankin's laboratory in Bombay, and did not find it had any protective effect. But then it was not actually the serum, but what he first published in the *British Medical Journal*.

22,390. You have had some experience of Haffkine's prophylactic fluid, have you not?—I have injected 708 cases here, and afterwards only three deaths occurred among them from plague.

22,391. Did these people voluntarily come forward?—More or less. Some compulsion was used, that is to say, they had privileges held out to them if they submitted to inoculation. If they were living in infected places, they were told that unless they became inoculated they would be moved out into segregation and health camps. In one Pet which I quote in my précis, Pantachakote, the total number of houses was 75 with a population of 160. There were 12 infected houses, and 3 people were inoculated between 11th October and the 11th November. There were only two plague deaths, and those two occurred on the first day after inoculation. I know that they themselves resorted to inoculation, because they had had a plague death in their house which they concealed until the next day.

22,392. How many deaths had occurred among the non-inoculated at that time?—The non-inoculated were compulsorily removed out of the locality. I believe there were cases and deaths among them. The whole locality had been infected, and perhaps 35 cases of plague had occurred in this district before inoculation was resorted to, so that the plague had got a grip of the place. The people were allowed to go back into their houses, and no other measures were taken, as far as I remember, as regards non-infected houses. The infected houses were opened up, and the others have since been opened up all over the place, because we could not distinguish between those which had been infected and those which had not.

22,393. Did you experience much difficulty in inducing people to be inoculated?—The people of Satara only resorted to it when we brought statistics before them to prove its great value. The personal factor enters into this matter a great deal, that is to say, the influence of the Collector or the doctor who is trying to get them to resort to this measure. Fortunately also, by the co-operation of some intelligent members of the community, we got the people to resort to inoculation this year, but last year we could not.

22,394. Is it proceeding now?—Inoculation has stopped now altogether; but plague is almost at vanishing point. The last Pet which was infected with plague has been completely evacuated, and that has practically stopped the plague for the last week or so.

22,395. The people are not now so much afraid of plague?—I think they have been educated a good deal.

22,396. The total number of cases which you appear to have inoculated is very small relatively to the population; were serious efforts made to induce the people to become inoculated?—At first we had a public meeting which was announced long beforehand. There were addresses by the Collector, the Deputy Collector, and myself, and we inoculated some Europeans and a child of a public officer in the presence of the assemblage, about 2,000 or 3,000 people. That had a great effect. Then, afterwards, the police offered themselves for inoculation.

22,397. Did you take other means to induce people to be inoculated?—Yes, and to give them an opportunity of judging of its value for themselves.

22,398. And they had ample opportunities for being inoculated?—Yes, three operators were ready to inoculate.

22,399. More than was required?—We used to wait for them two hours in the morning and one hour in the evening.

22,400. That is the utmost you effected in this town?—Yes, but this year plague has not been so bad.

22,401. Have you noticed if any effect is produced upon the progress of other diseases by inoculation?—I have had experience. Where once the reactionary fever has occurred gonorrhœa and gleet have been cured. It has also a great modifying effect upon syphilis.

22,402. How many cases of venereal disease have you seen cured?—Twelve cases of gonorrhœa, two of gleet and only four of syphilis. Unfortunately, I became ill when this was discovered, and so I could not investigate it further.

22,403. How long had the gonorrhœa lasted?—One has to trust the word of the patient; they say for two or three months.

22,404. How many injections were required?—Only one full injection.

22,405. How soon after were the symptoms stopped?—Up to the third day.

22,406. Were these cases verified?—Yes, I have inquired into them, and had the people come up before me.

22,407. Have you seen any cases in which inoculation has done harm?—In Satara I had seven cases which I inoculated, in which what one might call abscesses formed, although I did not actually see pus but only a clean watery serum exude. That was due to the fact that the contents of the bottle had become deteriorated.

22,408. Have you any other facts bearing upon the value or otherwise of inoculation?—Compared with evacuation, I would say that, if everybody could be induced to become inoculated, inoculation would seem to have a greater effect than evacuation, as evacuation is carried out now; but ideally, evacuation with the precautions I have mentioned, would be equally successful with wholesale inoculation.

22,409. Do you speak of partial or complete evacuation?—Complete, and the person should have full advantage of fresh air, on which the value of that evacuation depends.

Capt. G. S. Thompson, I.M.S.
—
eb. 1899.

22,410. You think that there are limitations to the value of inoculation as a plague measure?—Yes. You cannot get the whole of the people to agree to inoculation, and, therefore, you must resort to other temporary measures in addition. It would be a very good thing if you could get the people to resort to inoculation wholesale.

22,411. Do you think it is hopeless to get them to do so?—I think so. We cannot trust to it alone, it is only a temporary measure for dealing with plague, because although vaccination is of use for small-pox, it has not stamped out small-pox. In the same way we cannot trust to inoculation alone to stamp out plague. No one, in the face of an epidemic, has expressed an opinion that it will check the further progress of plague for the time being. I look on it only as a temporary measure.

22,412. What do you regard as the most fundamental?—Radical sanitary reform, teaching the people to alter their habits, which is the secret of our exemption, except in the case of plague pneumonia, which any of us might get any day.

22,413. Even in the open air, you mean?—Yes.

22,414. Will you give us your views with regard to the incubation period of plague?—I have known cases where it has been above the ordinary accepted period of ten days. This was amongst families in which more than one attack occurred. There were:—

3	instances	11 days	after removal to segregation camp.	
1	,,	13	,,	,,
1	,,	14	,,	,,
3	,,	15	,,	,,
1	,,	19	,,	,,
2	,,	20	,,	,,
1	,,	26	,,	,,

22,415. Let us take the last. What was the cause of infection in that case?—I have noticed about that the possibility of the man having revisited his house to bring away cooking pots.

22,416. Those are cases which occurred in the segregation camp?—Yes, with the only exception of the man on the 26th day.

22,417. I suppose you apply that possible source of error to all the cases?—There is a possibility of that, but we were quite certain of this particular case; there was a definite history that he actually had visited his plague-infected house to remove cooking pots, but the others were very carefully watched, and the seals of their houses were not allowed to be opened. We had all the locks sealed, and the people were not allowed to break the seals except by permission of the Divisional Officer, and in the presence of the authorities.

22,418. Was there a roll-call at any time of the day?—Yes, that is the practice.

22,419. At what times?—In the morning and evening, and sometimes surprise visits are paid into the huts, in order to find if all the segregated people are in the huts assigned to them.

22,420. The evidence, on the whole, would seem to show that these men, other than the case you mentioned, had, at least, not slept in any hut outside the camp?—Quite so.

22,421. Further than that you cannot go, I suppose?—No.

22,422. Have you any tabulated statement respecting the duration of the incubation period?—I have, and I will put it in, as follows:—

ADDITIONAL EXAMPLES of PROLONGED INCUBATION, 1898-99 EPIDEMIC.

GODOLI HEALTH CAMPS.

No.	——	Admitted.	Attacked.	Incubation.
				Days.
1	Dhondi K. Sidhu -	22.11.98	2.12.98	11
2	Shanker Vishnaranath.	22.11.98	5.12.98	14
3	Case No. 73 -	14.10.98	27.10.98	13
4	,, 74 - -	13.10.98	27.10.98	14
5	,, 83 -	14.10.98	2.11.98	18
6	,, 96 - -	13.10.98	7.11.98	24
7	,, 110 -	1.11.98	14.11.98	13
8	,, 113 - -	5.11.98	16.11.98	11
9	,, 114 -	26.10.98	18.11.98	23

RANCHATRI PLAGUE HOSPITAL, 1898-99.

10	Case No. 11 -	18.1.99	1.2.99	16
11	Prisoner in jail camp "under guard."	10.1.99	21.1.99	11

Such examples occurred in about one per cent. of the people segregated as contacts.

22,423. It there anything further which you wish to bring under our notice?—The only thing I wish to refer to is, the inverse relation between the height of the temperature and the intensity of the plague epidemic "in a place with a variable climate." That is the most important point in the statement. I have observed the minimum temperature at 8 a.m. We have not self-registering thermometers. At 4 a.m. it would be more telling still. In a place with a variable climate like Satara, when the temperature falls the plague increases. I have prepared a chart, which I produce.* When the temperature is generally lowest, or soon after that, you have a rise in the plague attacks. The chart shows a rise of temperature up to 82, which is our maximum in the hot weather, and there are no cases; and again, in the epidemic of this year, a fall in temperature, which corresponds to a rise of plague attacks. Generally, throughout the chart, the same thing occurs. Of course, there is a time when the epidemic will wear itself out, and then, although you have a fall of temperature, you may not have a great rise of deaths, owing also, perhaps, to measures which have been taken. Perhaps the town is half evacuated for instance. The only objection to that is places like Karachi, where they have had an epidemic of plague in the middle of the hot weather. But I can explain that, because there is no very variable climate, it is very equable, and the habits of the people are not altered by the cold or hot weather.

22,424. Therefore, you come back to the old proposition, that temperature has nothing to do with it, but that it is a matter of fresh air?—This fact of the temperature has also been noticed in the *British Medical Journal* by two doctors. Dr. Polverini and Dr. Galeotti, of Bombay, have written a book noticing the same point.

22,425. And giving the same explanation?—I do not know that.

22,426. In your opinion, plague is an easily prevented disease in civilised communities; what is your reason for saying so?—The knowledge of sanitation and our increased knowledge of plague and the conversion of medical men to the real, true, etiological theory of plague will put everyone on their guard as to how plague may be avoided. It is easily avoided, because we know that Europeans, and the other classes I have mentioned, are immune, and the reason is that they enjoy, and habitually provide themselves with, fresh air. When everyone knows how to do that, they never need be afraid of plague at all, except plague pneumonia.

22,427. (*Mr. Hewett.*) Have you noticed that persons of any particular ages have escaped plague here?—I do not think any definite statement could be made upon that point.

22,428. What is the mortality among the very young—children under five years of age?—33 under the age of five out of 1,152, but one would require to know the number of children living under that age in the town.

22,429. But you know there is a large population, and the fact remains that only 33 got plague out of 1,152?—The impression remains upon my mind that children are not so liable to plague. The adult age, in fact, is the age for plague, but, naturally, there are a great many adults among the population, and their work probably exposes them more to infection.

22,430. Have you observed any places which were infected last year, and have escaped the infection this year?—My work has only to do with Satara.

22,431. Have you observed that any portion of the town escaped last year, and got infected this year?—The Pets which were most infected last year have almost entirely escaped this year. I have tried to account for this, firstly, on the ground of general disinfection; secondly, the people being better educated; thirdly, their not visiting their sick relatives so much; and fourthly, that they have obeyed the rules

* Not published in the Commission's Proceedings.

which, I say, are the primary sanitary safeguards which will enable them to resist plague.

22,432. Do you think that the wards of the town which have escaped this year have enjoyed more fresh air than other people?—Yes, from both example and inducement of the leaders of their community, they are following these supreme sanitary safeguards, and running the risk of dying of diseases which they thought were caused by cold air rather than die of plague.

22,433. Are we to understand that the great majority of the people in places infected last year have altered their mode of living?—Not more than in Pets that were being affected, but native doctors have told me that many in the city are following these safeguards with regard to ventilation and cleanliness of their houses.

22,434. But not more in the uninfected than in infected localities?—I could not state that as a fact.

22,435. Do you feel confident that where you have noticed infection by rats, you have been able to exclude the possibility of cases of plague having occurred among human beings before the rats began to die?—Yes. I have an example in which we very nearly cleared out the infected district, and a large area round it in the first epidemic.

22,436. I was not speaking so much of places within a town, but of a village or town which has got infected from another place?—I had that experience this year, because plague was definitely found to be conveyed by rats, I think, from the little hamlets outside the city into the city by the road which the plague afterwards travelled.

22,437. What distance would that be?—About 600 yards from the village, and there were intermediate places which had dead rats.

22,438. You have no proof of rats having carried the plague a further distance than that?—No, that is my limit.

22,439. At what time of the year did these two places, Limb and Rahmatpur, get infected?—I think, perhaps, in July, but I am only speaking from memory.

22,440. Was it during the rainy season?—Just at the end of the rainy season we began to have dropping cases, but my connection with the villages was naturally not close, because I have been wholly on plague duty in the city.

22,441. Do you think that the people were in the habit of visiting the infected sites after they went out into these huts?—That is possible, but so far as police protection and visiting at night to see that the people were not living in the town are concerned, that was excluded.

22,442. Do you know how many police were looking after the 6,670 inhabitants of Rahmatpur?—I do not know about Rahmatpur.

22,443. How many people were there in Limb?—About 4,587.

22,444. How many police were there to look after them?—Perhaps 30 at most.

22,445. What do you exactly mean by partial evacuation?—In a commercial town, or in a large city, you cannot have wholesale evacuation of the place. There are obvious objections to it, such as trade, &c., and therefore blocks are evacuated, as we did in the beginning of the 1897 epidemic. The infected houses and those for 100 yards round, say, were evacuated, and also the houses which were closely packed together.

22,446. Did I understand you to say that partial evacuation at Satara had led to the dispersal of the plague?—No; I said it failed to stamp it out. The rats conveyed plague from the infected to the non-infected area, and therefore, I think, quarantine and isolation cannot stop plague, unless you can quarantine the rats and other animals.

22,447. Was there plague here in February and March 1898?—Yes, I think so.

22,448. To what extent?—About 30 cases during the whole month of March.

22,449. In the last half of February?—About 60 from the 15th to the 28th February.

22,450. There appear to be ten instances in which plague cases occurred in houses that had been disinfected during February and March 1898?—Yes.

22,451. A certain number of them appeared during the period of incubation calculated from the date when the persons affected are known to have been in contact with persons suffering from plague, but there are others which occurred after that period. Do you contend that the cases which occurred after the period of incubation could not have been contracted by communication with persons living outside those houses?—That was not likely at that time, because the population of the town was very much reduced. Instead of 25,700, it was about 4,000, certainly under 5,000. Therefore, the friends of those people were out of the town, and there was not so much intercourse between them or between others who are not friends as at ordinary times.

22,452. During the time in which these ten cases occurred you had 90 cases in the town altogether; is it not possible that those people got infected otherwise than through the infection being in the houses which they re-occupied?—I do not believe that merely visiting a house during the day will give a person plague if he has been living and sleeping in sanitary surroundings for some time. For instance, we, who are visiting Plague Hospitals, do not carry away infection to our houses, nor did the natives who visited the hospital.

22,453. You do not exclude the possibility of these people having been in the habit of visiting other plague patients in their own houses?—That may be possible, and I do not exclude that, but there would be very few instances.

22,454. Still, it is possible?—I admit that it is possible.

22,455. Are you satisfied that on the occasion of the disinfection of the houses in February, 1898, the solution of perchloride of mercury was actually one in 1,000?—I can make this statement that so far as human agency and foresight—by Europeans as well as Natives—could make it perfect, disinfection by perchloride of mercury, even in the last months, was so. The perchloride of mercury was acidulated with hydrochloric acid, as Hankin recommended. It was carried out as early as it could be. I made it a point to give disinfection by an acidulated solution of perchloride of mercury, the best possible chance of proving its efficacy, although I did not believe in it.

22,456. Who prepared the paper you have just handed me on the subject of the period of incubation?—I, myself, did that.

22,457. Are you responsible for the letter-press?—It is in my own handwriting.

22,458. You say in it: "It is to be noted that re-"infection and concealment accounted for attacks "beyond ten days from the initial case in a family "amongst segregated families. No case of undoubted "plague developed beyond the tenth day of observa-"tion except in one instance, and this person had "been allowed to visit his house after segregation, "and had been known to remove some articles for "use"?—That was a case in which I could not find positive proof, but it was possible in the others.

22,459. I understand you to say a great deal more than that?—There I may have, but I have modified that opinion. That was written a long time ago.

22,460. (*The President.*) You do not agree with what you have written here and you wish an opportunity of re-writing it?—Yes; my opinion may have altered.

22,461. (*Mr. Hewett.*) I wish to know why it has altered?—It has altered from experience. I have found instances since then which extend definitely beyond ten days.

22,462. None of the cases which you have mentioned later are referred to in this letter-press?—No, I have added those cases.

22,463. Where did these cases occur?—In Satara during the first epidemic.

22,464. Do these figures which you gave in answer a question of the President, relate to the people who are referred to in the letter-press?—Yes.

22,465. Why have you changed your opinion here?—Because I have had larger experience since I wrote it. I think in those cases it was not possible for the people to visit those houses, in fact, the seals were not broken.

22,466. Why did you think it was possible when you wrote this opinion?—At that time I did not enquire as to whether the seals had been broken or whether the people had permits.

Capt. G. S. Thompson, I.M.S.
27 Feb. 1899.

22,467. How long after these people had been in the segregation camp did you enquire as to whether the seals had been broken?—Before the end of the epidemic, when I was making up my figures for the whole epidemic again.

22,468. How long afterwards was that?—At the beginning of April.

22,469. When did you write this opinion?—On the 12th March. I wrote this before, in Bombay.

22,470. When did you write your opinion which I have quoted to you in a previous question?—Before the 12th March.

22,471. And when did you write down the figures which you gave to the President?—Before the 12th March also.

22,472. How long after writing your opinion did you change your views?—About four weeks.

22,473. Do you think that it is possible you might change your opinion again?—One always thinks the last opinion the best just as one thinks one's last religion is the best.

22,474. Do you think that none of these persons who were infected in the contact camp could have been infected from being in the neighbourhood of the contacts who became ill while they were in the camp?—I do not think they could, because if what I hold is true, and I believe from my experience that it is true, one cannot catch plague, so to speak, by coming into contact with a plague patient in our sanitary camps.

22,475. Then your deduction as to the period of incubation is entirely dependent on your view that you cannot catch plague by coming into contact with people in the camps?—I think that is so.

22,476. I understand that you wish to place before the Commission facts with regard to certain cases which led you to change your view with reference to the period of incubation?—Yes.

22,477. In these cases are you able entirely to exclude the possibility of the infection having been caught outside the camp in which the affected persons were located?—No, but these people only have left the camps, say from 12 to 2, under a system of passes.

22,478. Why could not they have evaded the guard at night?—We were all supposed to control that under the guard.

22,479. Do you consider that it is possible to keep people in under those circumstances?—No, I do not.

22,480. A certain number of people were taken out of that Pet, and out into the segregation camp. Sixty persons who had been inoculated were allowed to remain in the Pet, and none got plague; but among those who went into segregation a certain number developed plague. I want to know the number?—(The following statement, containing particulars as to plague among persons segregated and inoculated, was afterwards furnished by witness:—

Inoculation Statistics in three Divisions of Satara City 1898–99.

Name of Division.	No. of Houses.	No. of Infected Houses.	Population.	No. of Persons Inoculated.	After Segregation among the Non-inoculated.		After Inoculation among Inoculated.		Date of Evacuation and Inoculation. Week ending.	Remarks.
					No. of Plague Cases.	No. of Plague Deaths.	No. of Plague Cases.	No. of Plague Deaths.		
Durga - -	78	2	333	60	3	2	—	—	7th Nov.	No case since 17th January.
Raviwar -	68	13	292	107	13	10	1	1	8th Dec.	No case since 6th December.
Pantachakote	75	12	160	83	10	7	2	2	10th Nov.	No case since 24th November.
Totals -	221	27	785	250	26	9	3	3	—	—

The three attacks and deaths among the inoculated were on the 1st day of inoculation.

There have been no further attacks among the inoculated, all under strict observation, up till 31st March 1899. Some of the non-inoculated went out, after ten days detention under observation, into fields and to other villages or towns where they are not under strict observation and it is not known if any of them were attacked by plague.)

22,481. Have you had any corpse inspection here?—Yes.

22,482. Who inspected the bodies here?—In the first instance the Hospital Assistant. I was alone here during the height of the epidemic, and when he was in any doubt as to whether he could declare a case to be plague or not, I was sent for. I have even gone to the Muhammadan cemetery at half-past eleven at night to examine bodies.

22,483. Did you find any difficulty in carrying out corpse inspection?—There was no objection as far as I was concerned nor with regard to the medical subordinates.

22,484. Are there many Muhammadans here?—There are 2,789 Muhammadans.

22,485. That is a very small proportion of the total population?—Yes.

22,486. Are the Muhammadans an influential community here?—Very few of them are of any standing.

22,487. Have you noticed anything as to the effect of plague among the ordinary diseases of the population?—I am of opinion that a person who has had syphilis suffers much less from plague, or rather, survives a much more severe type of plague than a person who has not.

22,488. Have you observed that an outbreak of plague affected the general mortality from other causes?—I have not noticed that.

22,489. Perhaps you will put on record the facts which came to your notice with regard to the immunity of persons in the Parel Hospital, of which you had charge in Bombay?—In upwards of 240 instances the friends of the patients attended their sick, and in 20 instances scarcely ever left the bedside, and in not a single instance did the disease spread to the friends. Out of more than 140 attendants on the sick, belonging to the hospital staff from time to time, only one sweeper was attacked, and he had been constantly helping in the *post-mortem* room, and had a very mild attack with small axillary bubo.

I have also statistics to show the non-infectiousness of plague amongst servants in Plague Hospitals, when they are properly hutted on the premises, at Satara, in 1897–9, as follows:—

Ranchatri Plague Hospital, 1897–8:—27 servants and one plague attack and death, disease *not* contracted in hospital, *vide* "Bombay Medical and Physical Society's Transaction," March, No., p. 11.

Ranchatri Plague Hospital, 1898–9:—14 servants; no plague.

Wadha Camp Hospital, 1898–9:—22 servants with one attack and death which was in the person of a corpse bearer, and the source of inspection could *not* be traced as he was in the habit of going outside the hospital camp. The Medical Officer in Charge was able to exclude any recent or special source of hospital infection where the man had been on duty for seven months.

Budhwar Hospital, 1897–8:—27 servants; no plague.

Godoli Camp Hospital, 1898–9:—14 servants; no plague.

The above figures include only *bonâ fide* attendants upon the sick and not policeman, 22 in number, who were engaged at and in the Hospital Compound, and were completly immune. No notice is taken of changes in the establishments (add 20 per cent., say), in this return, which is compiled from the designations of the offices. Total servants 104, with two attacks and two deaths. The conclusion is that special exposure to plague miasm (?) in freely ventilated Plague Hospitals is not specially liable to lead to an attack of plague. It is to be borne in mind that it is not the *locâle* of a man that saves him from plague, but the habits as regards hygiene that he follows. No doubt those attacked had insanitary habits, and slept covered up in their blankets, and endeavoured to shut out the cold air in the early mornings, especially of the cold season, and rendered themselves equally liable to attack as the patients they attended had done in their hovels. Occupation *per se* is no preventive of plague. To find complete immunity among such a number of attendants, specially exposed to infection, would argue their possession of habits of living to which they had been strangers hitherto; but that so few were attacked is contrary to what we would have expected.

22,490. Have you noticed a case of a person having plague more than once?—Only in one instance, and there, I think, it was rather a relapse.

22,491. You had one case of a second attack of plague?—Yes, and another patient had a relapse.

22,492. Can you give us some details of the second attack of plague?—It was in a woman, aged 40. She had been convalescent 18 days, and was attacked 27 days after the initial symptoms of the primary attack, and died five days afterwards.

22,493. (*The President.*) Was the woman you speak of as having had plague twice still in the hospital when she was attacked the second time?—Yes, but in the convalescent ward, nearly separated.

22,494. She did not quite recover?—She was able to walk about.

22,495. But you say that she relapsed?—I consider the interval too long, but that was a matter of opinion.

22,496. Was it a case of bubonic plague?—Yes.

22,497. (*Mr. Hewett.*) Have you examined the registers of deaths in the town of Satara?—From the 31st July 1897.

22,498. Do you feel certain that every death is reported?—Yes.

22,499. Are you certain that the cause of death is properly reported?—It was not verified in each case. There was no necessity, because there was no indigenous plague.

22,500. How could it be verified if a death had not to be reported until 72 hours after it occurred?—It could not; the body would be disposed of.

22,501. Did your inquiries lead you to believe that deaths were all reported within 72 hours, and never afterwards?—No. That point did not come up.

22,502. Was it the practice for a medical man to examine the register of deaths?—It was submitted to me daily. The Secretary brought it either to my bungalow, or I went to the Municipal Office to look at it.

22,503. From what date?—I arrived here on the 30th July, and I immediately started to watch the daily mortality. That was the point I was keen on.

22,504. Was it the custom for the Civil Surgeon to examine the register before plague occurred?—Only for a short period I, myself, was here.

22,505. You began it on account of plague?—Because of my apprehension of plague—that the plague was within striking distance, so to speak.

22,506. In the ordinary course, does a Civil Surgeon in the Bombay Presidency look at the registration of deaths within Municipal areas?—I should say that is a very exceptional custom.

22,507. Has he any duties as Health Officer in ordinary circumstances?—No, except in a very cursory manner, looking after the streets and latrines, and that sort of thing. I do not think his duties amount to anything more than, perhaps, suggesting means, and that there should be more filth carts—sanitary arrangements.

22,508. (*Mr. Cumine.*) You are going to give us the figures in Satara town and Satara district of the first and second epidemics. Will you give us the periods, in order that we may see whether the town or the district was ever completely cleared of plague for any appreciable period?—(The following statement was supplied by witness subsequently):—

SATARA DISTRICT PLAGUE RETURNS, 1897–99.

22,509. In the rains, in a non-evacuable town, what are the best practicable measures to adopt, according to your experience?—In the absence of evacuation, wholesale inoculation is the next best thing.

22,510. What is the best thing to do with the patients?—If you can, you should isolate them with one attendant in a well-ventilated room in their own house. There is no danger of attending them there. I have on my own responsibility tried that in one case here, in which the family were allowed to remain in their own house. The room in which the patient remained was plague-proof, as I call it, and no case followed. Of course, it was a dangerous experiment. The house was well ventilated, and not overcrowded.

22,511. Did you put the patient on a bed?—Yes.

22,512. Did you throw disinfectants on the floor every day?—There were no chemical disinfectants, but the house was disinfected with sunlight and air. I wanted to try the effects of my own theory as far as possible.

22,513. Were the people in the house attacked?—No

22,514. You did this with one patient only?—Yes. There were five other members of the family. Of course, it was done on my own responsibility.

22,515. Have you any information of outbreaks of mumps appearing in children in a village in which the plague epidemic had died out?—I have no instance of that.

22,516. When the perchloride of mercury solution had been prepared, and was about to be applied to the houses, did you ever take a sample and test it to see what its strength was?—No.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Collector's Office, Satara.

FIFTY-SEVENTH DAY.

Tuesday, 28th February, 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President.*)
Mr. J. P. HEWETT. | Mr. A. CUMINE.
Mr. C. J. HALLIFAX (*Secretary*).

Mr. V. G. Ghanekar.

28 Feb. 1899.

Mr. V. G. GHANEKAR called and examined.

22,517. (*The President.*) You are a pleader at Satara?—Yes.

22,518. (*Mr. Cumine.*) In what town have you had experience of plague?—In Satara city.

22,519. In Satara city Municipal limits only?—Yes.

22,520. What were the preventive measures taken when plague had been discovered in Bombay?—Observation camps and detention camps were first established on the roads leading from the railway station and Poona to Satara city.

22,521. Medical inspection was introduced?—Yes, and names of strangers who used to visit the city were every day registered on different posts, with their addresses. These persons were to be visited by inspecting Karkuns every day.

22,522. How was infection brought into Satara city?—From Karad, I think.

22,523. By human agency?—Yes.

22,524. And having regard to this fact, you think, I understand, that persons from infected localities should not be allowed to come to the limits of an uninfected locality?—Yes.

22,525. Putting on one side human agency, what other agency is there by which infection is carried from one village to another?—By the clothes of infected persons.

22,526. Have you any case where infection was clearly carried by clothes?—From Satara city infection was carried to Yawateshwar.

22,527. How did the clothes go there?—A Mahar was engaged where the dead bodies were to be burnt, and there was a report to the effect that he took clothes from the dead bodies to his relations on the hill, and by those means the plague was carried from Satara city to Yawateshwar.

22,528. Was that verified?—That is what was said, but it was verified also.

22,529. Could the Mahar not have caught plague himself?—That Mahar who carried these clothes did not catch plague.

22,530. Do you think that in an infected village rats may carry plague from house to house?—Yes, in Satara city I observed that. I saw from my own personal observation that rats carried infection from house to house.

22,531. Have you seen them going from house to house?—No; but if one house was infected the next neighbouring house was also infected.

22,532. When plague breaks out what do you think the most valuable remedy is?—Evacuation is the most successful remedy.

22,533. How long would you keep the people out after evacuation?—From my last experience I think that they should be asked to leave the town for four months.

22,534. If they went back to their houses sooner, what would happen?—Perhaps they would be attacked with plague.

22,535. Have you any instances where people went back within a shorter period and got plague?—Yes. I have instances of some disinfected houses, and as soon as they went back into those houses they were attacked with plague, and they died. The Jailer's house is an example.

22,536. We do not want a disinfected house, but one that has not been disinfected. We want to see how long the germ takes to die. You say four months; have you any instances of people who went back within a shorter period than four months to a house that had not been disinfected, and got plague?—I have no particular instance.

22,537. Why do you say four months?—The last particular time all the inhabitants of the city were out for four months; and afterwards they were allowed to go in. We did not notice any plague case occurring in the houses that were inhabited after four months.

22,538. What would you do with the patients?—According to the present Government orders they have to be segregated.

22,539. But what would you do with them?—If the house is well ventilated I would allow the person to remain in it.

22,540. Has that been tried at all?—No; because according to Government standing orders we were not at liberty to keep a patient in his house.

22,541. It is not within your experience whether it would be a dangerous course or not?—I could not get experience at that time, because we were not allowed to leave the patient in the house, although the houses were well ventilated.

22,542. Is the carrying away of the patient to the Plague Hospital offensive to the feelings of the people?—It is very offensive. In one case that came under my notice the patient, as soon as he was told that he was to be taken to the Plague Hospital, died. It was I who went to that patient and told him that the order was passed that he should be taken to the Plague Hospital. As soon as the ambulance came he was told that it had arrived, and he died.

22,543. If you leave the patient in the house what would you do with the rest of the people in the house?—I would allow one or two of his relations to attend on the patient, and the others I would ask to go into the segregation camp in the open air.

22,544. Would they object very much to that, do you think?—They would not object, I think, if the huts are well built and well ventilated.

22,545. How would you manage in the rains?—In the rains it is impossible.

22,546. What is your experience of disinfection of infected houses with chemicals?—I have no belief in disinfection, because it is very costly, and it cannot be properly done. The houses are not pucka built, and in the tiles and roofs, and other places, the germs will not be killed by disinfection.

22,547. What is your evidence of this?—Because many cases have re-occurred in houses which have been disinfected.

22,548. Are you quite sure that the chemicals were properly prepared?—There were special officers appointed to make the mixture, and I must assume that the chemicals were properly prepared.

22,549. Have you many actual instances where people returning to a disinfected house got plague?—Yes, I have about 10 cases.

22,550. Can you exclude the possibility of their having caught infection from some friends outside on the road, or from other houses?—They were not allowed to go into other houses.

22,551. Not after their return to their own houses?—Yes, after their return they were allowed; but they stealthily went to their houses without permission, and they died there.

22,552. But may they not have gone stealthily to other people's houses too?—I cannot say that.

22,553. You think, I understand, that poorly-fed people were, to a large extent, victims of plague?—Yes.

22,554. Do you think that plague is got much by touching plague patients?—No, because every day I used to visit the Plague Hospital, and touch the patients, and I never got plague.

22,555. But I suppose it is necessary to have boots, or something, on one's feet?—Yes, that is necessary.

22,556. Is sleeping on the ground dangerous?—Yes; sleeping on the ground is dangerous, even in the day or in the night: they got plague.

22,557. What are your views regarding the co-operation of the people, as being necessary for the successful carrying out of plague measures?—I believe that the people should be induced to act according to the wishes of Government. If they do not co-operate, then these measures will not come into proper operation. It is necessary that they should co-operate.

22,558. Is there any marked difference in the behaviour of the people now, as contrasted with their behaviour in the first epidemic?—Yes. As regards evacuation, last time, when they were asked to evacuate their houses, they were unwilling; but now that they have received their education with regard to plague, as soon as they see any infection is coming, they willingly leave their houses.

22,559. But do they understand the danger of their going back stealthily to their houses to sleep?—Some do, not all.

22,560. (*Mr. Hewett.*) Was it at about the worst period of the outbreak of plague that these ten cases occurred of people going back to disinfected houses, and getting plague?—No, it was not at all during the worst time; most of the cases occurred in February.

22,561. How many cases were there in February?—99 deaths.

22,562. There was then a considerable amount of plague in the place at the time?—Yes; there was a certain amount of plague in the place.

22,563. Are you a Municipal Commissioner?—I am a Municipal Commissioner; and, at that time, I was a Municipal Commissioner too.

22,564. Is there a byelaw of the Satara Municipal Committee which requires a householder to report every case of death in his house?—There is a byelaw that all persons are required to give information to the City Municipality within 72 hours after death. But that was not made with regard to plague.

22,565. I am not speaking about the plague, I am speaking about a byelaw before plague occurred?—There is a byelaw to that effect, that every person in whose house a death occurs, should give information to the Municipality within 72 hours, and if he does not give that information he will be liable to a fine of five rupees.

22,566. Has everybody in Satara always complied with this byelaw?—As regards death everybody complies with it.

22,567. Has any instance come to your notice in which it has not been complied with?—No.

Mr. V. G. Ghanekar.

28 Feb. 1899

22,568. Every death since that byelaw was passed has been properly and punctually reported?—Yes.

22,569. Was the mortality rising when plague was detected here?—Yes, day by day it was rising.

22,570. Was the first case that was found out to be plague reported by the householder?—No.

22,571. How was that?—He could not say it was plague, the death only was reported.

22,572. Was the death reported?—Yes, the death was reported to the Municipality.

22,573. When a report is made that a death has occurred from a particular cause, does any medical officer examine the report?—No.

22,574. It is merely filed in the Municipal office?—Yes.

22,575. What is done with the reports of plague?—When a report comes to the Municipal office, then a Hospital Assistant is asked to examine the dead body, and if he says it is not plague, then the body is allowed to be taken to the burial ground. The register of deaths is kept at the Municipal office.

22,576. (*The President.*) You are in favour of allowing patients to be kept in their houses?—Yes.

22,577. In the case where you allow a patient to remain in his house, you allow some people, of course, to remain to look after the patient?—Yes.

22,578. How do you prevent visitors from outside coming in?—They should be asked not to come in.

22,579. There are no special means adopted?—No.

22,580. Do you not recognise that to be a possible danger?—As regards a well ventilated house, I do not see any possible danger.

22,581. You think it is quite safe?—Yes; and besides it is against our Hindu notions to take a patient away from his house to a Plague Hospital; our habits of living and our notions are against it.

22,582. One would not compel it to be done unless it were required, and if it came to be a public danger, habits would have to be set aside to some extent, would they not?—Yes, that is so.

22,583. Is it part of the difficulty that in the hospital they are isolated from their friends?—Yes.

22,584. Could that not be got over by allowing a certain number of their friends to come and see them just as if they were in their own houses?—That difficulty can be got over by allowing friends to see the patients in hospital, but when the patient himself is unwilling to go to hospital, how can the difficulty be got over?

22,585. Do you find that difficulty as great now as it was at the commencement of the epidemic?—The difficulty is still in existence.

22,586. You do remove certain patients?—Yes, we remove them, but they are unwilling.

22,587. You have a hospital, I think, for plague patients, have you not?—Yes.

22,588. And patients are taken there?—Yes.

22,589. Are they only the patients from houses where the accommodation is insufficient, do you think?—Almost all patients are taken.

22,590. You are not now adopting the plan of treating patients in their houses?—No.

22,591. Therefore, it is a practical measure, and you can carry it out?—Yes, we can.

(Witness withdrew.)

Lieutenant N. B. Anderson, I.S.C., called and examined.

Lieut. N. B. Anderson, I.S.C.

22,592. (*The President.*) I believe you are in the Indian Staff Corps, and have had a good deal to do with plague work in Karachi and Satara?—Yes.

22,593. You are now engaged here?—Yes; I am Plague Supervising Officer.

22,594. (*Mr. Cumine.*) I will ask you about the Satara district first. How many infected villages have you now under your management?—Nineteen, spread over an area of about 1,000 square miles.

22,595. What do you think is the great remedy when a village is infected?—Entire evacuation, immediately.

22,596. When plague has regularly "caught on" in a village, do you find that partial evacuation is successful?—No.

22,597. When is it successful?—If there is a wadi some distance from the village, it might possibly not go to the village.

Lieut. N. B. Anderson, I.S.C.

28 Feb. 1899.

22,598. I suppose if you take the epidemic early enough, when there have only been two or three cases, you might succeed with partial evacuation?—Yes; but I do not think so if a case occurred in the village proper.

22,599. Do you attach great importance to carrying out evacuation promptly?—Yes.

22,600. Does the duration of the epidemic depend upon the time the evacuation occupies?—Yes.

22,601. When, after evacuation, cases still keep going on amongst the evacuated people, after the expiry of the period of incubation, to what do you think that is traceable?—It is generally due to the people visiting their houses surreptitiously.

22,602. Supposing that the plague had been only in one corner of the village when the people went out, and after some time a man whose house is in the opposite corner goes back to his house, do you find that he is liable to get the plague?—He is practically certain to do so. Infection spreads through the emptied village just as it would do if people were there, only more slowly.

22,603. In cases where you leave a few human barometers in their houses in the villages, do you find those people especially liable, or do they escape?—I think they are especially liable to infection.

22,604. From the fact that cases keep on occurring amongst evacuated people in consequence of their surreptitiously visiting their houses, I suppose that evacuation must be accompanied by the preventing of people from visiting their evacuated houses, must it not?—Yes; all should be done that is possible to prevent them.

22,605. Do you find that with so many villages to manage you are able to do this in the case of each village?—Where there are good village officers, it can be done; but where there are not, it cannot be done.

22,606. Do you think evacuation is practicable in the rains?—No; I think not.

22,607. Even when you do evacuate in the rains, is there in the huts in which the evacuated people are living sufficient ventilation to prevent the plague "catching on" to the floor in the same way as it does in a house in the village?—I think the huts are frequently worse than the houses in the village.

22,608. In what way?—In being worse ventilated.

22,609. What is the result of that?—The result is that a large number in one hut will frequently get plague.

22,610. When the hut is apparently infected in that manner, what would you do with it?—Remove it to another place.

22,611. What is your opinion with regard to the effectiveness of disinfecting with liquid disinfectants—for instance, perchloride of mercury?—As it has been done it has been of no use.

22,612. How do you draw that deduction?—Cases have occurred in houses which have been disinfected.

22,613. Who prepared your perchloride of mercury for you?—I have not done any disinfection with perchloride of mercury here. It has been stopped during this cold weather.

22,614. Have you tried the kiln system of disinfection at all?—No.

22,615. You have had no experience of it?—No; but I burned the floors with grass in one village.

22,616. Have you any experience of inoculation in the Satara district?—None.

22,617. How do think plague is carried from one village to another?—I think, practically, it is always by human agency.

22,618. How do you think it is carried from one house to another within the same village?—By rats, and also it seems to travel of itself; there are very few rats in some villages.

22,619. Do you evacuate all villages as soon as they are found to be infected?—Yes; immediately.

22,620. But I suppose all villages become practically unevacuable in the rains, do they not?—Yes.

22,621. The effectiveness of evacuation depends to some extent upon the size of the village, does it not? For instance, you could not evacuate Bombay town?—No.

22,622. Does it depend also, to some extent, upon the employment of the inhabitants?—That sometimes adds to the difficulty of getting them out of the village.

22,623. In what way? Who are the most difficult to get out?—Brahmans, Banniahs, and Sahukars.

22,624. Have you noticed whether there is a specially high mortality amongst children just before an epidemic, or just after one?—I have not kept any figures with regard to it, but there has been a high mortality amongst children in several villages just before an outbreak of plague.

22,625. Have you noticed that the same villages are getting infected this year as were infected last year, or in the two previous years, or does the plague this year seem to choose villages it did not attack before?—It has attacked both.

22,626. You have nothing to observe upon the matter?—No. The plague shows no preference for one or the other.

22,627. Have you noticed any case in which there appears to have been a genuine recrudescence of the old germ within the village itself?—Not that could be called a recrudescence.

22,628. It has been re-infection?—Yes. Cases have occurred on paper as recrudescent, but they were not really so.

22,629. Do you do any corpse inspection?—Yes; in the larger villages it has been done.

22,630. Is it offensive to the feelings of the people?—Yes, I think it is.

22,631. Have you noticed whether there is any decrease in the virulence towards the end of an epidemic?—The epidemic is always finished up in the fields; but I think just as many people die amongst those who get plague as in the earlier stages; the proportion of deaths is not smaller.

22,632. Have you noticed whether swellings in the necks of children seem to occur to a remarkable extent after the close of an epidemic when plague is supposed to be extinct?—No, I have not noticed that.

22,633. Have any cases come under your observation of people getting plague twice?—None.

22,634. In the fair weather, amongst the evacuated people living in huts, do you find that if one plague case occurs in a hut it is liable to infect the neighbouring huts?—It does not follow; it occasionally occurs.

22,635. Which of the measures are people so convinced of the usefulness of, that they will adopt them themselves in the future?—Evacuation, certainly.

22,636. Do they do their best to keep out infectious strangers?—It depends on whether they have influence or not. A man with influence will get into the village.

22,637. Do they appreciate the danger of returning to sleep in their infected houses after they themselves have been evacuated?—I think they do, but they prefer to run the risk, and make sure that their goods are all safe.

22,638. Is there great difficulty in guarding their property in the empty village site?—There is a great deal.

22,639. Do you find that dacoities begin?—Yes, they do.

22,640. Do the people ever boycott those who insist on going to their houses and laying the rest of them open to re-infection?—No.

22,641. Do you find that they readily report the fact of their village being infected, or do they conceal it up to the last moment?—That entirely depends upon the village officers.

22,642. Have any cases come to your notice where they have sent off an express messenger to you to let you know of the first appearance of plague?—Yes, in one or two villages they have done so. The majority of the villages, however, do not do so.

22,643. Coming to Karachi, I believe you served there during the greater part of the first epidemic?—Yes.

22,644. And during the whole of the second?—Yes. In Karachi I was during the greater part of the first outbreak, and during the whole of the second, in charge of the Jail and Market Quarters which include the Joria Bazar, in which quarter the plague was more severe than elsewhere.

22,645. Were there any reasons for this?—There were, I think, three principal reasons for this:—

I. The plague originated in this part, and when it had become severe the inhabitants of other parts left before the full strength of the infection had time to reach there.

II. The Joria Bazar is the grain bazar of the city; and rats therefore abound in this neighbourhood in enormous numbers. No less than 105 were found dead in one house.

III. The narrowness of the streets and insanitary condition of the houses, especially the existence in them of wells and cesspools, which attracted the rats to them from the grain godowns.

22,646. Did the disease spread very rapidly in the Market Quarter?—In the Market Quarter the spread of the disease was exceedingly rapid, and was I believe conveyed entirely by rats, dead ones being found in almost every house in the quarter. The number (105) mentioned above was the largest found in any single house, but 75 were found in another and 65 in a third.

22,647. What reason had you to believe that rats moved about from one house to another?—In one or two houses where the walls were touching, I have seen them go from one house to another.

22,648. What reason have you to believe that they carried infection to human beings when they did go there?—Because cases have occurred in very many of these houses, and the first cases occurred where there were most rats, round the grain bazar.

22,649. How was it, in your opinion, that rats were enabled to spread the disease to such an extent?—That the rats were enabled to spread the disease to such an extent was due, I believe, to the insanitary condition of the houses and the wretched way in which they are built. In that portion of the Market Quarter in which the disease was most severe, the houses are mostly very old and built of mud plastered over a framework of sticks. Latterly, stone fronts have been built to some of them, but the house behind its imposing exterior remains the same as before. The foundations of these houses are saturated with sewage and filth of every description. There is generally a cesspool below the house which has not been emptied since the house was built and the neighbourhood of which is honeycombed with rat holes, and which is probably situated close to a well from which water is drawn for washing, if not for drinking purposes. This evil was aggravated by the narrowness of the streets and the scarcity of windows. The Municipality have followed a fatal policy of allowing householders to encroach upon the streets and selling them strips of land in front of their houses until it has been absolutely impossible to sell any more. Overcrowding, moreover, exists to a terrible extent, especially amongst the Meghwars (weavers), who are, I should imagine, the filthiest class of people in India. So dirty are they and such outcastes, that in their own country they used to be, and I am not sure are not still, branded each with the initial letter of his village, and wherever he may go he is never allowed to sleep within the limits of the town or village. It is, therefore, not surprising that the plague was so severe in this quarter. Any epidemic disease would, I think, be the same. It is a notable fact that in the really good houses, some of which were situated in the very heart of the most highly infected quarter, practically no cases occurred.

22,650. Did you notice in what kind of floors the plague seemed to flourish best?—Most of the floors were cow-dung floors. Houses with cemented and tiled floors did not suffer so badly.

22,651. Do you think that the drainage system of the town had anything to do with the excessive severity of the plague?—No, nothing whatever.

22,652. Does a drainage system really exist at all?—Only so far as carrying away dirty water from a very small percentage of the houses is concerned.

22,653. Are the houses connected with the sewers?—No, very few; perhaps some half dozen.

22,654. Has much been done in Karachi since the epidemic to improve the ventilation of the houses?—Yes, a very great deal.

22,655. What is the value, from your experience, of sleeping upon a bed as contrasted with sleeping on the floor?—People who sleep on beds run far less risk of catching plague, I think, than those who sleep on the floor. In one house in the Market Quarter everyone in the house got plague except one old man, who lay on the only bed.

22,656. Do you think that the people still have a great dread of the hospitals?—Yes, I do. There is, no doubt, that a very large number still have a dread of hospitals, especially Government Hospitals, and also of segregation, but the greatest dread of all is that of being carried away in stretchers, which is very genuine, and I think it is best never to use them at all.

22,657. Did you disinfect with perchloride of mercury in Karachi?—Yes; all the houses were disinfected.

22,658. Did you find it effective there?—No; cases occurred in some of the houses which had been disinfected, which were re-occupied; no further re-occupation was allowed.

22,659. Could you exclude the possibility of infection having been brought in again from some neighbour?—I think it was probably brought in by rats again.

22,660. So that you cannot say that disinfection did not perform its duty properly?—No; but if so, its effects were counteracted immediately afterwards.

22,661. Do you think that after a certain time the plague germ will die of itself without any disinfection?—Yes.

22,662. At what period do you put that?—Between three and four months.

22,663. Why do you select that particular period?—Because I have known people going back after nearly three months, and they have got the plague.

22,664. Do you find a shorter time is necessary in the extremely hot weather?—That I have not noticed.

22,665. Though disinfection may be of no use when there are a great many rats infected, and plague is very severe in a town, can you say it would not be of use where only two or three cases have occurred in a town?—No.

22,666. Do you think it would be useful then?—I think it might be useful then.

22,667. If you do not use disinfection to an infected house, what would you do to it?—Evacuation is all you can do. The entire disroofing of infected houses is by far the most effective measure. The opening of holes in the roof and walls, though it is doubtful, I think, if it has much effect at the time, forms, provided the openings are transformed into ventilators and windows, a vast permanent improvement.

22,668. What is your experience of inoculation at Karachi?—I had coolies working in my division, at a daily strength of about 50. Twenty cases of plague occurred amongst them up to the end of the first week in May. There were probably more, as more men disappeared; but there were certainly 20 cases which I was able to trace. I had half the men inoculated on the 7th of May and the other half a week later. One man developed high fever after he was inoculated, and died on the fifth day. After this, no case ever occurred amongst these men, who worked for two months subsequently in the most highly infected quarter of the town.

22,669. Are those the men who had already come unscathed through the plague, while the other 20 men died or disappeared?—Half of them would be; the other half would be fresh men.

22,670. Besides these coolies, have you any experience of inoculation of any other people in Karachi?—Yes.

22,671. Who?—Some 900 people living in my division were inoculated, and there was only one case among them.

22,672. But were those 900 people of all classes?—People of all classes. Some of them were actual contacts, and they did not get plague afterwards.

22,673. Were there amongst them representatives of classes amongst whom you think plague would probably come? Or did they all belong to the upper classes who would not be so likely to be infected?—They belonged to all classes; but many of them belonged to the Borahs and upper classes, who are less liable to be infected.

(Witness withdrew.)

Lieutenant H. C. Steen, I.S.C., called and examined.

Lieut. H. C. Steen, I.S.C.

28 Feb. 1899.

22,674. (*The President.*) I believe you have been occupied in connection with plague matters at Satara?—Yes, in the southern part of the district.

22,675. You are a Staff Corps Officer, are you not?—Yes.

22,676. (*Mr. Hewett.*) How long have you been employed on plague duty in the Satara district?—Since the 19th of November, 1897.

22,677. Have you been continuously in the villages ever since that period at all seasons of the year?—Yes, I have been in the district ever since then.

22,678. Will you tell us what your experience has been as to the way in which a village gets infection?—I think it is almost entirely by the visits of people from infected villages to non-infected villages. I have had one case in which that has not been so.

22,679. When you say you have had one case in which it was not so, do you mean one case in which you were not able to establish that it was so?—I mean a case in which the infection was brought by other means.

22,680. Would you specify those other means?—It was supposed to have been brought to a village called Bambavda in the Valva taluka, by imported tobacco. A cartload of tobacco from Bhatavda, a neighbouring village, is said to have brought the infection.

22,681. Did you investigate this theory?—I was not there at the time, and I did not hear of it until afterwards. Dead rats were reported to have been found in the house, and three cases of plague occurred.

22,682. In the house to which tobacco had been brought?—Yes. Those three cases were amongst the first cases in that village.

22,683. How far is this village from the one from which tobacco was brought?—About two miles.

22,684. Was there any communication between the residents of the two villages?—I think there is communication between those villages.

22,685. What do you yourself think of the theory of communication by means of tobacco?—The theory is, I suppose: possible.

22,686. Do you attach any importance to it?—I do, provided infection can be imported by means of tobacco, in which case, this being the only theory of the infection of the village, I accept it in the absence of any other. In any case it appears that tobacco was brought from the infected village to a non-infected village.

22,687. And also that the plague occurred in the non-infected village?—Yes.

22,688. But do you think that it is impossible that plague got to the non-infected village by other means?—I think it is quite possible.

22,689. Have you a number of villages in which you have been able to trace the infection to people coming from infected villages?—Yes.

22,690. How many villages?—Seven villages at least. I have been able to trace it, more or less clearly, in about seven villages, and without doubt in one or two.

22,691. And you have had no village in which you have been able to clearly discover any other source of infection?—No.

22,692. Have you been able to trace any source of infection from clothes?—No.

22,693. Have you anything to say as to the part which rats play in disseminating plague?—Rats, I think there can be little doubt, disseminate the plague in a village, once the infection has been imported by human agency. Communication may exist, and probably often does, amongst the careless villagers, but when cases of plague are found occurring in totally different, and well separated, parts of a village, and amongst the highest and lowest castes, at the same time, there can, I think, be little doubt that the rats have spread the plague over the village, especially as large numbers of these vermin are, as a rule, found dead in the village, either before or at the same time as the occurrence of cases amongst the inhabitants. As a rule, they disseminated the plague in the village site very rapidly indeed, especially if it has been concealed, and little or no evacuation has taken place; but sometimes, as was the case in Islampur, which really forms one village with Uran, the plague develops slowly.

22,694. As a rule it has been your experience that you have found local cases of plague before you have found mortality among rats?—I have experienced both sets of circumstances.

22,695. Which is the more common?—I think rats dying first. There have been a good many cases of the other sort.

22,696. When you say rats dying first, do you mean rats dying between an imported case and a local case?—Yes.

22,697. Have you any instances in which you have moved people out of any infected portion of a village site, and then when the village has been re-occupied the people in another part of the village which was not infected at the time when it was evacuated have got the plague?—I have not had any examples of that.

22,698. Have you, as a rule, evacuated the villages in which plague has occurred?—Yes, always.

22,699. Even during the rainy season?—Yes.

22,700. Have you found any difficulty in doing so during the rainy season in this country?—It is very difficult, of course, during the rains, but I have generally got the people out.

22,701. Do you think that the people in the black cotton soil districts when they are turned out of their houses in the rains suffer considerable hardship?—Yes, I think they do. I can instance two villages especially, the village of Marul in Patan taluka and the village of Vathar in the Karad taluka. I used to visit the inhabitants of these villages after they had been evacuated, and go round their huts. They were suffering very great hardships indeed. They were all living more or less in mud. Some of them had good huts, but a great many of them had very uncomfortable huts.

22,702. Do you think that the hardship of living in huts during the rains led people to go back to their villages at nights?—It is quite possible. It is hard to say definitely what they do. Even if one seals the village, you find the seals broken. It is difficult to be certain in the majority of cases whether they go back or not.

22,703. Do you think that it is likely that they go back?—I think it is extremely likely that they go back. About the end of January 1898, in the village of Kale in Karad taluka, which had then been evacuated for about three months, I found, as the result of a night search that I made, considerably over a hundred persons surreptitiously sleeping in houses that had not been disinfected. Kale was, after Karad, the worst infected village in the taluka, and many cases of plague had occurred all over the village owing to the impossibility of evacuating it quickly in the rains. These persons may have been indulging in such practices for a considerable time, as the village was not sealed, but no fresh cases of plague were traced to them. The plague, in fact, had been dead at Kale for some weeks previous to the time that I made the search.

22,704. Did you find that when you evacuated people during the rains the plague took longer to bring under when the people were in the huts than it would if you had evacuated them in the dry season?—In the two instances I have named it did take a very long time. I have had other cases since then in which it took quite as long, if not longer, when the village was evacuated in the dry season.

22,705. But in both cases—both in wet and dry seasons—the establishment under your control does not enable you to be certain that the people do not get back to infected sites?—No, it does not.

22,706. How many infected villages have you to deal with at the present time?—Four villages in one taluka, and nine in another, about thirteen altogether, of which six are fully infected with plague, the other seven not being very bad.

22,707. Have you noticed a circumstance which Colonel Hay referred to yesterday, that villages on the banks of a river are especially liable to infection?—I noticed that in Valva taluka recently—last autumn. The fact is, that a very large proportion of the villages in that taluka are on the banks of the river, but I do not altogether connect the fact of their being on the banks of the river with the fact of their having become infected.

22,708. Have you resorted to disinfection in the villages?—I was doing that in Karad taluka shortly after I first arrived, and until I left there about six months afterwards.

22,709. What did you disinfect with?—With a solution of perchloride of mercury.

22,710. Do you do it now?—No, I have not been doing it since last July.

22,711. Is that in consequence of orders having been given to stop it?—No; orders were not given to stop it; but I was told to do it to a very much lesser extent. I made up my mind that it was not very much good, and so I practically did not do it at all.

22,712. Why do you think that it is of no use?—My experience of disinfection in Karad taluka first led me to doubt its value, but I do not feel competent to say that it is of no use. I did not begin until the villages had been evacuated for some considerable time. The shortest period was two months. In some cases I did not begin until they had been evacuated for five or even six months. In the meantime there had been a certain amount of re-occupation of those villages.

22,713. Is your reason for not believing in the efficacy of disinfection by perchloride of mercury that you think that the germ would be otherwise disposed of within a certain period, or that you think that the solution of perchloride of mercury cannot be efficiently used so as to destroy the infection throughout the house?—I think, in the first place, that the solution does not kill all the germs; in the second place if the village is left alone long enough the germs will probably disappear in some other way. My experience in Karad taluka tends to convince me that the germs did actually disappear somehow or other in a great many of the villages which I disinfected. I was led to believe that the germs had disappeared before disinfection was begun.

22,714. How long do you think that it takes for the germ to disappear?—I think two months is the least time.

22,715. Have you noticed that any of the villages have been infected in both epidemics?—Yes.

22,716. Are those villages which had been disinfected or had not been disinfected?—Villages which had been disinfected, and others also. It seems to take fresh villages more or less haphazard. When, however, the second epidemic began in the southern half of this district it attacked villages which had not been attacked before; but since then it has attacked others. No recrudescence of plague occurred in any of the disinfected villages in Karad taluka for months, and only then through re-importation. This seems to speak in favour of disinfection. At Andumbar Wadi, however, in Tasgaon taluka, which was disinfected under the "kiln-burning" process, but which was evacuated only six weeks, three fresh cases of plague at once occurred as the result of the inhabitants merely revisiting their houses.

22,717. Could it attack others by reason of infected people having come from infected villages?—It could, of course, and that is the probable reason; but it is impossible to be certain, as the people never, or seldom, assist such investigations. There is so much communication between the people that it is difficult to say what they do and where they go, and they practically never tell you. I think in nearly every case the infection of a village is due to re-importation.

22,718. You have not observed anything to lead you to believe in a recrudescence?—No, I do not think so. There has always been some story attached to the re-infection of a village to the effect that some man had come from some infected village, and in his house or in the adjoining houses cases have almost invariably occurred.

22,719. Have you observed a village which lies next to a village which was infected in the first epidemic get infected in the second epidemic while the village infected in the first epidemic escaped?—I have noticed instances of this, but consider it largely pure chance; though, at the same time, it is, I suppose, a likely theory, that the formerly infected village will be less susceptible to fresh infection than the one which has never been infected at all. Such a theory might be explained by the possible extermination or diminution of the rat community, as to which I have heard several affirmative opinions. It seems to me, however, purely a matter of what the people do, where they go, and what communications they have.

22,720. Did any of your disinfecting coolies get plague?—I did not have a single case of plague amongst my disinfecting coolies during the four months that I was engaged in disinfection work in Karad taluka, though, as I afterwards discovered, they were utterly careless of the possible risks they ran. I ascribe this immunity to the fact that, when I began disinfection, early in January, 1898, the first villages treated had been evacuated and partially unroofed for close on three months, while some of those taken in hand later had been evacuated four, five, and even six months. In fact, I came to the conclusion that the infection in these villages had somehow or other disappeared of itself, and that there was, therefore, none left to disinfect. Later, in July, 1898, when I sent the same coolies to Khanapur taluka to disinfect the small village of Upala-wangi, which, however, had only just got infected, their carelessness of the risks they ran resulted in no less than seven of them, out of twenty-four, being attacked with plague.

Lieut. H. C. Steen, I.S.C.

28 Feb. 1899.

22,721. In what respect were the coolies careless?—I heard from the Hospital Assistant in charge that they had been particularly careless. I was a long way off and I had not visited them for some time. I heard they had been in the habit of buying clothes they found in the infected houses, and eating food similarly found, and, in fact, doing all sorts of careless things.

22,722. How long after that village had been evacuated was it that they went to disinfect it?—Less than a month, three weeks.

22,723. Have you recently, under your orders, tried disinfection by means of the kiln process?—Yes; it was tried in Tasgaon last August and September.

22,724. In how many villages was it tried?—It was tried in three wadis in Tasgaon taluka.

22,725. Did you employ the villagers themselves, or coolies, to do it?—I employed coolies permanently. When they had once learned the work they were more useful than other fresh coolies whom we should have had to be constantly teaching.

22,726. Who did the work?—Assistant-Surgeon Merchant personally supervised the work, I supervised the disinfection work generally.

22,727. Did you find that the coolies employed in disinfecting in this manner suffered?—The coolies must be careful, in whitewashing the dusty floor, not to raise the infected dust and so inoculate themselves with plague, a physically impossible task. A coolie with a whitewash brush first raises the dust, afterwards he may, or may not, whiten the floor. The coolies must also be careful to remove, without a doubt, the whole of the whitened top layer of the floor. When, however, they enter a room with picks and shovels, confusion at once reigns. The supposed dangerous top layer of the floor is cut up, flung about, mixed with lower layers, and the probability is that a very great deal of it is never removed from the house at all. For these reasons I consider the "kiln-burning" process a more dangerous one than that I employed. During the disinfection of three small wadies in Tasgaon taluka in September, 1898, four coolies died.

22,728. They exposed themselves to all sorts of risks, apparently?—Yes. My experience of coolies is that they are utterly careless.

22,729. Were the coolies as careless when they went to disinfect by means of the kiln process?—I fancy so. There was so much work on hand, and so many villages got infected at that time that I fancy they were left a good deal to themselves; they were always careless, and more so when not closely looked after.

22,730. How long after those three wadis had been disinfected by the kiln process were the people allowed to re-occupy them?—In the case of Andumbar wadi, it was six weeks, and in the case of Khandoba wadi a little over two months.

22,731. Did any case of plague occur in houses which had been disinfected in this way?—In Andumbar wadi three cases of plague occurred.

22,732. Were you able to trace the infection in this instance to any other place?—No; it was reported to me by Mr. Merchant, the Medical Officer in charge of operations, and he said that there was no evidence that infection had been imported in any other way. The people were allowed to revisit their houses for the purpose of cleaning them after disinfection, preparatory to re-occupation. Almost immediately, the same day or the next day, three cases of plague occurred amongst the people who had so revisited their houses.

Lieut. H. C. Steen, I.S.C.

28 Feb. 1899.

22,733. Do you infer from that that the kiln process was not efficient in this particular case?—It seemed to point so. I am not, however, prepared to say so definitely. It is just possible that there was some other reason for the occurrence of these three cases. One never knows what may have happened, what the people may have done. Some man may have gone to an infected village and returned.

22,734. Do you think that the unroofing of houses is a desirable measure?—I cannot say whether it kills plague germs or not: but I think it is an advisable thing to ventilate a house in this or in some other way. A good many of the houses I have had to deal with have probably never had any ventilation for years. Mud-roofed houses, especially, are so constructed that it is almost impossible to ventilate the interior.

22,735. Have you had any experience with regard to the use of passes to try and check the movements of the people?—Yes; I have been issuing passes myself, and supervising the pass system, but I do not think they have ever been effectual. Hundreds and thousands of people are going about without passes every day. It is almost impossible to deal with these people except under a very complicated system of passes.

22,736. Do you think that the people in the villages understand evacuation; do they think it is a good measure against plague?—They only appreciate it after a certain point. In nearly every case they will stay in the village till the last moment. When plague gets very bad they will go out of their own account.

22,737. Do you think that when plague has got really bad in that manner that evacuation will stop it in a short time?—It must be prompt, otherwise the village population quickly become infected, and then evacuation does not stop the plague, but only diminishes it. The case of Uran is an example of this. In the rains, however, I was almost forced to the conclusion that evacuation was a failure, even to diminish an outbreak. The hardships and extreme discomfort to which the people are exposed in the cold, damp, and unhealthy fields seem to render them so susceptible to infection, that they readily fall victims in large number to any plague that may be about. Vathar and Marul in Karad and Patan talukas respectively are good examples of this. Both villages were evacuated in very bad weather, and necessarily slowly; in the former village almost 20 per cent. of the population was exterminated. Subsequent experience, however, went to prove that even in the rains evacuation is better that non-evacuation. The village of Atke in Karad taluka became infected in September last year, when the rains were exceptionally heavy. The inhabitants could not be induced to evacuate the village, with the result that the daily attacks so increased that six or seven were common, a state of things were common, a state of things worse than prevailed at Vathar at any time. Atke is, however, a good example of where, plague being severe, complete evacuation stopped it. During the first half of October the plague was at its height. On the 14th of that month the village was completely evacuated, and by the end of the month the plague had almost completly died away. The village of Takari in Valva taluka is another, though not so good. Plague broke out on 4th October 1898. The plague was concealed for some time, but by the 14th the village was completely evacuated and by the end of the month the plague had stopped entirely. The village of Padmal in Tasgaon taluka is a good example of where, plague having been discovered early, complete evacuation stopped the outbreak in a few days. Plague appeared in the village on the 22nd June 1898. By the morning of the 23rd it was completely evacuated, and after six cases had occurred the epidemic stopped. This village also well evidences the fact of the locality being infected. On the 29th June disinfection was begun, the people had necessarily to revisit their houses, and on the 4th July the plague began again, resulting in 30 fresh cases. But the village of Ashta in Valva taluka bids fair to be the best example of all of the value of evacuation in stopping an incipient epidemic. Two cases of plague occurred in the very middle of this large and hitherto uninfected town on the 16th December 1898. On the 17th and 18th a large block was evacuated, which by the 23rd was extended so as to include no less than 90 houses. Four cases have occurred amongst the inmates of the first and an adjoining house, but with these the epidemic appears to have ended. There is little doubt, however, that two or three houses are infected, and so the whole block is rigorously sealed, and no disinfection or other interference with any of the evacuated houses is permitted.

22,738. Please give us the facts as regards Uran?—The outbreak was first discovered on the 25th of September; the infection was supposed to have been imported about five days before, about the 20th.

22,739. Did you evacuate the whole village then?—I evacuated it by large blocks. It was all evacuated by the middle of October.

22,740. Is plague still in existence there?—There is an odd case from time to time even now.

22,741. When was plague at its worst there in the interval between evacuation and the present time?—It was at its worst during the whole of October and November. During both those months plague was very bad.

22,742. Practically it continued to be very bad for two months after it started?—From about the beginning of October till very nearly the middle of December.

22,743. Have you anything to say as regards segregation of the sick and contacts in villages?—Segregation of all sick and contacts in a particular place ought to be an excellent measure for a village, provided it is thorough, as in this way the infection will be gradually weeded out of a community until the epidemic stops. But for carrying out this measure thoroughly at a large number of infected villages resources must be ample. I have been engaged in this work for over a year now, but am afraid I cannot say much for the results. My resources were necesarily limited, and in fact the arrangements have been practically in the hands of the people themselves. They are of the following rough and ready description. I choose a suitable piece of ground, and order the infected families to live there for the required time, building their own huts, as they refuse to live in huts erected for them. They are required to make proper arrangements for comfortable residence during their stay. I allow the patient and one attendant to remain behind in the fields. Separate camps, and sometimes even separate huts, for sick and contacts have been found impossible, as families are, as a rule, too small to admit of being broken up. An instance of the latter is where a family consists of a man, his wife, and two or three very small children. If the mother gets attacked with plague, the husband attends on her, and the children cannot be separated from their mother. Consequently the whole family live together in the same hut. Such cases are common.

22,744. (*Mr. Cumine.*) I believe you have only six villages infected now?—That is about the number of the *badly* infected villages; the total number of infected villages in my charge is more than double that.

22,745. What is the approximate area that they cover?—Thirty-five miles long, by about ten miles broad.

22,746. During the rains I suppose the people, in order to make themselves comfortable in their huts, have to close up the huts almost as much as their houses in the village?—Yes, they have to keep out the rains and so the top part of the hut must be more or less watertight. The door of the hut, when there is one, is almost always open. I consider that there is always more ventilation in the huts than in most of the mud roofed houses. There is sometimes a door to the hut, which is practically never closed, and would not make much difference if it were, as it is generally of loose construction.

22,747. Have you done anything in the way of corpse inspection in the villages?—Yes, I have inspected corpses myself; and they are always inspected either by the village officers, or the Circle Inspectors.

22,748. Is the inspection of female corpses offensive to the feelings of the villagers?—I do not think so, as I have never had any trouble on this head except with gosha families.

22,749. Though the people may not have made any actual opposition, have you any reason to suppose that it is offensive to their feelings?—No, as a rule I do not think it is. They show their corpses quite freely, both male and female. Before death, also, I have often examined both male and female patients, and have never noticed that my doing so was offensive to their relatives. The people are often quite callous as to what is done with their sick and dead.

22,750. Have you ever tried treating patients in their houses, instead of removing them to hospital?—No; I have had very few patients left in the houses, occasionally one or two. The village has always been evacuated more or less promptly, and most of the cases have occurred in the fields.

22,751. Have you noticed whether an excessive mortality amongst children precedes or follows an outbreak of plague in a village?—No; I cannot say that I have.

22,752. (*The President.*) What is the population of the village of Uran?—About 6,000.

22,753. I understood you to say that plague had been developed for several weeks before evacuation was attempted?—No, I did not mean to say that, if I did.

22,754. After evacuation, do you mean to say that the development was not checked, but rather increased?—I cannot say to what extent the plague would have developed if the village had not been evacuated, but considering that two, three, four, and even five and six cases of plague occurred daily in the fields for no less than six weeks or so after evacuation had been completed, the extent to which this measure checked the development of the epidemic can hardly be said to have been marked.

22,755. When was evacuation commenced?—The infected house was at once evacuated.

22,756. On the same day the first case was discovered?—Yes.

22,757. How long did evacuation continue before it was completed?—For about a fortnight.

22,758. That would be early in October?—Towards the middle of October.

22,759. Prior to this period in the middle of October how many cases had occurred?—I think only four in the village, but upwards of 50 in all in the village and fields, I will not be absolutely certain.

22,760. It was a small number?—Yes, inside half-a-dozen in the village only.

22,761. After evacuation was accomplished in the middle of October, how many cases occurred among those people who were evacuated?—I think upwards of 200, if not more than that.

22,762. Where were they evacuated to?—Into the fields. Each man went to his own field.

22,763. What house or hut did he go to?—Each man erected his own hut in his own field.

22,764. Did he construct the hut inside or outside the village?—He constructed his hut outside the village.

22,765. Under what directions or superintendence?—His own.

22,766. He put it wherever it liked?—Yes, in his own field.

22,767. In the open country?—Yes.

22,768. As near any other hut as he pleased?—Yes.

22,769. Were any directions given as to there being sufficient air space in these huts?—No.

22,770. As a matter of fact was there any ventilation?—There was a certain amount of ventilation through these huts, by the doors, and their loose construction generally.

22,771. Is there more than one door?—As a rule there is only one door, but in some cases there are two doors. In the majority of cases, however, there is only the door space, but no door. When the door space is required to be closed, a blanket is hung across it.

22,772. Of what material are the doors made?—The same material as the huts, karbi.

22,773. Were the doors kept open all night or shut?—I cannot say for certain, though as a rule, they were probably kept open. The majority of the huts were however doorless. A certain number of the huts had loose doors.

22,774. Do you know whether the huts were ever overcrowded or not?—I think in the majority of cases they are generally pretty full of occupants.

22,775. Overcrowded?—Yes.

22,776. Was any precaution taken to prevent communication between those people who had gone out, or who had been removed, and the villages or houses from which they had been removed?—The doors of the houses were sealed.

22,777. Did the people go back?—Many seals were broken, and so possibly some did go back, but as they were never found living in the village, except perhaps an odd family or so, those who did go back can only have paid a hasty visit. No considerable number ever went back and stayed.

22,778. The probability is that they did go back because these houses would not be broken into by other people, there are not so many burglars?—Most of the seals were broken by children and mischievous people. I several times found that the seals on the doors of the compounds were broken, while the seals of the houses themselves were intact.

22,779. Were there many such cases?—Yes, a great many were like this. The evidence clearly pointed that the seals had been broken by mischievous persons.

22,780. You examined a good many houses and found this out?—Yes, I examined the villages regularly after evacuation.

22,781. And in nearly all these cases the outside seals had been broken, while the inside seals remained intact?—Yes; in the large majority of cases. The inside seal was not broken, but the seal on the large outside door leading into the courtyard was broken. Children and other mischievous persons did not seem to care to take the trouble to climb over walls for the purpose of breaking the inside seals.

22,782. The actual living rooms could not be entered without breaking the seals?—No.

22,783. Were there any windows by means of which the rooms could be entered?—Practically none.

22,784. I suppose in a certain number of these cases of seal-breaking, it was not done with mischievous intent?—In a certain number of cases it might have been done out of spite. The people knew generally that if seals were broken somebody would be punished. If a man had an enemy he would probably break the seal on his door.

22,785. Do you attribute any of the seal-breaking to the people themselves attempting to go into their houses?—I think only a very small proportion, if any, was due to this cause, the majority of cases were, apparently, due to either mischief or spite.

22,786. Can you tell me whether, in your opinion, in any instance whatever the people went back into these houses?—In a very few, odd instances, I have found persons paying temporary visits to their houses, and in an equally small number of cases I have found persons come back to stay.

22,787. From the precautions which you took can you say with confidence that they never did go back?—No, I cannot.

(Witness withdrew.)

(Adjourned till Wednesday, 1st March, at Belgaum.)

At The Collector's Office, Belgaum.

FIFTY-EIGHTH DAY.

Wednesday, 1st March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

MR. J. P. HEWETT. | MR. C. CUMINE.

MR. C. J. HALLIFAX (*Secretary*).

Mr. G. Carmichael, I.C.S.

1 March 1899.

MR. G. CARMICHAEL, I.C.S., called and examined.

22,788. (*The President.*) You are the Collector of Belgaum?—Yes.

22,789. You have had experience of plague in Sholapur, Kaira, and Belgaum?—Yes.

22,790. In regard to Sholapur, at what time did you have experience of plague?—In September 1897.

22,791. Were you there long?—I was only there for a month and a half after the plague began, and then I was transferred.

22,792. You cannot say much about it?—No.

22,793. Do you know how it originated in Sholapur?—I think that it was brought by Mr. Thatcher's servant.

22,794. Did you leave before the epidemic had ceased?—Yes.

22,795. Can you tell us, generally, what were the measures adopted while you were there?—Evacuation was not attempted, and we only tried to prevent the people from leaving Sholapur. We took the sick to hospital, and then the segregation camp was started.

22,796. While you were there, was the epidemic being brought down markedly?—Oh, no, it was going up rapidly.

22,797. The measures that you speak of do not appear to have been effective?—They were not effective.

22,798. With regard to Belgaum, is your experience only of the city, or of the cantonment and the city?—Only of the city.

22,799. Did you see both epidemics?—No, I came at the height of the second epidemic only.

22,800. Do you know how it originated?—In the city it began on the outskirts next the cantonment. There is nothing in between the city and the cantonment but a ditch and a wall. All the streets on the side of the city next the cantonment were first infected.

22,801. What did you infer from that?—That rats carried it from one to the other.

22,802. Was the city infected from the cantonment?—Yes.

22,803. At what date did the second epidemic begin?—It began about August 1898. There were a few cases in July. It has not really been clear, except for about four weeks after the first epidemic. It has not been quite clear, without a single case, for a whole month.

22,804. You think it was spread by rats?—I think it was brought over from the cantonment by rats, and also by the people, because we could not keep the people from the cantonment out of the town. From the fact that so many cases in the beginning occurred in the streets next the cantonment, I thought that not the people only, but the rats carried it over.

22,805. Were there many dead rats found in the city during the previous epidemic?—There were, but I cannot say from personal knowledge, as I was not here at that time.

22,806. That was in the rainy season?—Yes.

22,807. What were the measures which you adopted?—When I came here the people were left in their houses, and the only measures that were being carried out was disinfection of houses, and disinfection of burial parties.

22,808. Were the people segregated?—The people were not segregated, except for the time it was necessary to disinfect their houses. After their houses had been disinfected, and their clothes disinfected, they were allowed to go back to their houses again, and the sick were not removed to hospital unless they went voluntarily.

22,809. What time did that occupy?—From one to two days at most.

22,810. Did the sick generally live in houses with more than one room?—It was the usual house here, a long, deep, narrow house, with doors at the narrow ends. There are usually three rooms in it, each opening into the other. The two outside rooms have doors, the middle one being quite dark, with no windows.

22,811. So that they were able to move a patient to one of the other rooms while the room that had been occupied by the sick person was disinfected?—Yes.

22,812. Was that done?—Of course they were kept in one of the rooms, but you could not possibly keep the people separate.

22,813. While disinfection was going on, what was done with the people in the house?—They were taken to the segregation camp, and there their clothes were disinfected, and meantime the house and everything in the house was disinfected.

22,814. You say the people who were not infected in this house were removed to the camp?—Yes, the people who were not patients.

22,815. What about the patients?—The patient was left in the house, and the people were left in the house until he had either died or recovered.

22,816. In the meantime no disinfection was done?—No, that was done afterwards. If you had several cases occurring one after the other, sometimes it was a fortnight before the disinfection was done.

22,817. Was any special means taken to prevent communication from outsiders with this house?—We tried to do it, but it was of very little good.

22,818. What were the means?—Only advising the people not to leave the house.

22,819. There was nothing like a cordon?—No.

22,820. Was that effective in keeping the people from going into the house, or not?—No, I do not think so.

22,821. As a general result, were those measures successful or not successful?—We had a large death-rate, but I do not know that we had a larger death-rate than we would have had if we had segregated the people.

22,822. You did not segregate the people, but as a matter of fact did the plague go on growing, or did it not increase?—It went on growing. In October it went up to 60 attacks and 50 deaths for one or two days, and then it went down.

22,823. Whatever your method was, it failed to stop the epidemic?—Yes.

22,824. Did the epidemic continue into the dry weather?—It continued into the dry weather. Of course we persuaded a large number of people to go out, and at the end of the year there were only about 18,000 people in the town out of a population of 30,000.

22,825. Did the epidemic still continue?—Yes, we were still getting occasional cases here and there in the town, about three a week or four a week.

22,826. What was done with the people who went out? Did they go where they liked, or was there any kind of regulation as to where they should go?—We helped them to build huts in different places round the town, and they went out into them.

22,827. In certain prescribed places?—We helped them to select places.

22,828. Were there fewer cases among those who went out than among those who remained in?—There were.

22,829. How did you disinfect?—We disinfected with perchloride of mercury. We had disinfecting gangs who opened up the house and sprinkled the whole of the walls and floors with the solution, and steeped the clothes in the tub of perchloride of mercury, and then swept out the house and burnt up all the rubbish outside.

22,830. That was only the infected house?—In one or two cases we did the streets, whether the house had a plague case or not, but we did not attempt to do it all over the town. In the other part of the town we only did it in houses where plague cases had occurred.

22,831. In that one street did you remove the people altogether, or what did you do with them?—They went out. I ordered it to be evacuated.

22,832. How long did they generally stay out?—Many of them are out still.

22,833. There is no rule in the matter?—No.

22,834. Within what time might they return to Belgaum? Would any of them come back within a few days, or did they all stay out?—I cannot say definitely. Once they go out they all stay out, except the weavers, who get permission to come in and work in their houses in the daytime but not to sleep in them.

22,835. Do you know of any cases in which a disinfected house having become re-occupied has become again an infected house?—We have had several cases of that.

22,836. Can you give us an instance?—I cannot quote you an instance, but I think there are several stated in Mr. Uchgaonkar's précis of evidence.

22,837. At any rate, you know they did occur?—Yes.

22,838. You also did a good deal of inoculation with Haffkine's fluid?—That was done before my time, practically at the beginning of the first epidemic it was done. In December and January most of it was done.

22,839. That was before you came here?—Yes.

22,840. Have you no personal knowledge of it?—No, but I know the way they collected the statistics. Mr. Uchgaonkar has given the inoculation statistics in his précis of evidence.

22,841. Have you any opinion as to how long a village ought to be evacuated?—I cannot make a rule as to the time of it, but about three months after the last case, if possible.

22,842. You have not sufficient grounds to go on?—I have only dealt with one or two villages yet. It is only three months after the rains, and we could not evacuate during the rains.

22,843. I think you state in your précis that after that period of three months re-entering the house appears to have been safe?—If the house had been ventilated and thoroughly cleaned out.

22,844. That is only an opinion, you have no reasons for it?—I cannot give you any facts except judging from the villages that have had an epidemic, and it has passed over in the rains without any evacuation.

22,845. The epidemic ceased in those villages?—Yes, without anything being done; without much evacuation, and, in some cases, without any evacuation.

22,846. You have some cases without any evacuation, and without any disinfection?—Yes.

22,847. Do you remember those cases?—Neginhal was one instance.

22,848. What is the population of that village?—2,949. It was infected on the 21st July 1898, and the disease died out at the end of September.

22,849. How many cases were there?—496 cases and 391 deaths.

22,850. When this large number of plague cases was occurring, did the people not remove themselves from the village?—Some of them did.

22,851. To a large extent?—About half of them went out.

22,852. Therefore you had about 496 cases among 1,500 people?—I do not say that those that went out did not get cases.

22,853. They may have got cases?—Yes.

22,854. Do you know where they went to?—They went into huts round the village site.

22,855. Are you sure that they did not go to other villages?—Some of them may have done so; probably a few did.

22,856. Not a large proportion?—Not a large proportion of the whole.

22,857. Had you any means of knowing that—I mean by a census of the people who had gone out?—A census was kept by the Supervisor.

22,858. In the camp?—No, in the village. He made a census of the village.

22,859. I am talking of the people who left the village?—I am talking of the village as a whole, not of the village site. We make a census of the villagers, and those that leave have to get permission from the subordinate officer in charge of the operations there. In his daily statement he puts down how many people left the village, and we have to depend upon him.

22,860. It is recorded?—Yes.

22,861. Can you give us the number of villagers who went into other villages?—54 families, or, say, 300 people at most.

22,862. I suppose your view is not, however, that an infected village ought to be left to itself?—No, I do not think so.

22,863. If an infected village is left alone, experience shows that it suffers a very high mortality?—Yes.

22,864. What are your views about the importance of disinfection?—Disinfection with perchloride of mercury I do not think has much effect, except that it cleans out the house and airs it out for the time being, but if it is shut up afterwards it is just as likely to get infected by rats as it was before.

22,865. I asked you if you had instances in a town of where houses were re-occupied after disinfection. That would be the proof?—It is no proof, because we cannot tell where the infection was caught, whether it was in the town, or whether it was caught elsewhere, or in the house.

22,866. Why do you think disinfection was not effective, and that it was of no value?—It was done so much in the jail, and it did not stop the disease there.

22,867. Would you tell me the facts that came under your observation of what happened with regard to plague in the jail?—We first had a case on the 17th November. The man was found sick one morning and died at 9 o'clock at night, and two days after that we had another case. We had 10 cases altogether—four deaths and six recoveries.

22,868. Would you tell me how that bears on disinfection? You have not referred to that yet?—After each case we disinfected the whole of the jail. It is a small jail, and the clothes and everything about the prisoners were disinfected.

22,869. Nevertheless you had a succession of cases following each other?—We kept on getting cases.

22,870. Within what time did these cases occur?—The most of them occurred within one month, and then there were two isolated ones—after we had inoculated a good number—at the end of December and the middle of January. In the meantime the prisoners, after a week in the jail where they got the plague first, were removed to the small Civil jail, and some of them got it there.

Mr. G. Carmichael, I.C.S.

1 March 1899.

22,871. Did many of these cases occur in the small Civil jail, or nearly all?—The first case was on the 17th. There were two cases on the 18th, two on the 20th, one on the 22nd, one on the 24th November. These were all in November.

22,872. But why do you think that is a case proving that disinfection was of no use?—We disinfected every day the whole of the wards.

22,873. You have given me seven at least out of these 10, which all occurred within the incubation period. They might have been all infected at the same moment. There were only three left, which may have occurred in the other jail?—The next one was on the 1st December, and the next on the 23rd December. When the jail was vacated we moved into the new one on the 26th December.

22,874. The last case that occurred in the small Civil jail had nothing to do with the disinfection which you carried out in the other jail?—No.

22,875. Do you think it is important to disinfect clothing or other movables?—Yes, I think it is of great importance.

22,876. Have you any proof that it is of great value?—No, I do not think I can give any case.

22,877. It is just an opinion?—Yes.

22,878. You state in your précis that you think that clothes carry the infection. Have you any cases that seem to show that?—There is a case at Ugargol. There were six cases all in one house on the 2nd of October, and the man had come from Dharwar in the middle of August, and he had not gone back to Dharwar, as far as I could ascertain.

22,879. I do not quite see how the clothes carried the infection in this case?—It could not be incubating all the time. I say the usual way in which the villagers are infected is that some of them bring in infected clothes or other articles into the villages. It is not necessarily incubating on the man himself when he comes to the village.

22,880. Can you give us examples of clothes or other articles, apart from a human being, having brought plague?—I cannot mention any particular article that brought it.

22,881. How do you separate the person from the article?—Because plague is said to incubate at 10 days. If you had a man who was living in a village for a month—if he is going to have plague—if he conveyed the bacillus in his person—it would have come out and he would have had plague before.

22,882. I do not quite understand how that applies to this case?—This man came to Ugargol from Dharwar, which was, at that time, infected with plague.

22,883. When did plague occur in Ugargol?—He went to Dharwar on the 2nd of August. He came back in the middle of August, and the case occurred on the 2nd October—a month and a half afterwards.

22,884. But were not there other opportunities for infection?—That was the only infected village at all. It was the first infected in that part.

22,885. You think this shows he carried some article which was infected?—Yes, I think so.

22,886. Have you any other cases?—Then there is the case of Yedur. Dead rats were found in a coolie's house. That was the first intimation that plague was in this part of the village. The coolie himself did not die or any of his family until 15 days after the dead rats were found.

22,887. You think the rats were the cause of it?—I think rats got it first before human beings got it.

22,888. How do you think the infection originated in the house?—The man must have gone to some other village and infected the rats.

22,889. Do you know of your own knowledge of any inoculated persons acquiring plague?—Yes; there was the case of two persons in the jail.

22,890. Have you any others?—I cannot vouch for others.

22,891. What is your view as to the best measures to adopt? What, in your experience, is the most effective step to take when plague has occurred in a district or village?—For the people to go out and evacuate a village.

22,892. You have said you do not think disinfection was sufficient?—I think disinfection is a very good thing in dealing with imported cases, and segregation also. If you have an imported case, before plague had spread in a village, I think disinfection is good.

22,893. There are two kinds of conditions in the villages: one is where the village is largely infected—where there is a large number of cases in that village, then you think the best plan is evacuation?—Yes.

22,894. And on the other hand, where you have only one or two cases?—If they are indigenous, it does not matter—evacuation still is the only hope of saving the place.

22,895. If they are not explainable by importation, then you also think evacuation is necessary?—Yes.

22,896. But if they are explained by importation, what would you do?—I would have the man out and disinfect his house thoroughly.

22,897. On what theory do you draw the distinction?—I think it is spread by rats. If the rats in the village are not infected, and if they do not get the plague in houses in which imported cases occur, then it is not likely to spread to the village.

22,898. You do not know of any case occurring in a village in which there was no mortality among the rats?—No, not as far as I know.

22,899. (*Mr. Hewett.*) In Sholapur was there a byelaw for the registration of deaths?—Yes.

22,900. Did the Municipal Committee carry out the byelaw thoroughly?—I do not think so.

22,901. Is there a similar byelaw in the Belgaum Municipality?—There is.

22,902. Can you give us an estimate of the proportion of the population who ran away from Belgaum city during the second outbreak?—I am afraid I could not give you an estimate of those who ran away.

22,903. Do you think that many ran away?—Not a large proportion of them. At the beginning of the first epidemic there were a lot of strangers.

22,904. At the beginning of the first epidemic you had a large extra population?—Yes, I believe so.

22,905. What proportion of the population here at the beginning of the first epidemic ran away?—Less than one-fourth, I should think.

22,906. What I want to try and make out is, whether in your opinion a larger proportion of the population ran away during the first epidemic than in the second epidemic?—I do not know—I could not say.

22,907. Do you think that the fact that rigorous measures were not taken during the second epidemic encouraged the people to stay in the town rather than to run away?—Yes, in the case of the poorer people.

22,908. Could you state exactly when you first began to be able to get the people out of the town during the second epidemic?—It was well into November before we got an appreciable number out.

22,909. Was the disease on the decline when you got them out?—Yes, it was going down. The highest month was October and part of November.

22,910. By the time you were able to get them out, the disease had begun to decline somewhat rapidly?—Yes, of itself. The fall was comparatively rapid in November.

22,911. Could you state the number of villages which are infected in your district at the present time?—About 60.

22,912. Are they scattered all over the district?—They are mostly in the south.

22,913. How many European officers are employed on plague duty in the villages at present?—Six.

22,914. With that number can you insist on the effective carrying out of the measure of evacuation under European supervision in each individual village?—It is enough if we have good circle men under them. They instruct the circle men, and the circle officers go round.

22,915. Do you regard any agency except European agency as really reliable in the matter of evacuating a village, and seeing that people do not get back to the village site?—I think it is necessary; I do not think native agency is sufficient.

22,916. I suppose these European officers who are working the district have to move long distances from one infected village to another?—Yes, they have.

22,917. In addition to the villages which are now infected, you have had a large number infected at different times; could you give us a statement to show the number that have been infected in each month from the beginning up to February?—(The following statement was subsequently supplied by witness):—

	Villages.
Newly infected in 1897:—	
November	3
December	1
Newly infected in 1898:—	
January	12
February	8
March	8
April	3
May	3
June	5
July	7
August	28
September	33
October	37
November	34
December	27
Newly infected in 1899:—	
January	22
February	21

22,918. When did the villages in your district begin to be infected?—In January and February 1898.

22,919. Have certain portions of the district remained continuously infected ever since then?—Yes; certain portions of the district have always been infected since then.

22,920. Do you think that the evacuation of a village in the Belgaum district is accompanied during the rainy season with great hardship to the people who have to be evacuated?—I think it is a very great hardship.

22,921. Do you think that the hardship involved in evacuation is likely to make the people more liable to other kinds of illness; I am speaking of exposure in the rains?—I know that the Deputy Collector reported that the health of the only village which did evacuate during the rains was good.

22,922. Is it your opinion, the infection having been brought to a particular area by either a person, or clothes, or other effects, the person himself not being infected, that the disease passes into the rats, and that it takes some little time for it to become localized among the human beings of the place?—Yes, I think so.

22,923. I see from a report made by the Superintendent of the jail, that he seemed to connect the outbreak in it with the fact that the first man who got plague had been taken out from the jail to be placed under trial?—Yes.

22,924. Why do you think that this was not the method in which the jail became infected?—Other prisoners began to get plague immediately after the man was infected; and dead rats were found before. I cannot say that for certain: that is my impression.

22,925. The Superintendent says that the first one was found on the 19th; do you think they were found earlier than that?—I believe they were; but I have no proof of that. I only know that they removed the grain to a different place from where the rats were found. Shortly before, I believe, rats were dying, and they removed the grain; but they did not report it.

22,926. Was there plague in Gokak at the time?—Yes.

22,927. How far from the jail was plague in existence at the time in Belgaum?—The jail is on the top of the hill, about 300 yards from the nearest house in the town where there was plague.

22,928. Was there any plague among the warders in the jail?—No, I do not think there was. None of the warders took it. The jailer was living in the corner of the jail. He moved his family shortly before the outbreak—about the same time as the grain was removed.

22,929. I believe you were going to say something about the statistics of inoculation which have been separately furnished to the Commission. The statistics that have been prepared were prepared under your general directions, were they not?—Yes, under the directions of Colonel Peters, I.M.S., and myself.

22,930. Could you describe the manner in which they were prepared?—The record is not very complete. It is very difficult to identify the inoculated people in several cases, because there was often a single name entered, and very little else. A certain proportion is like that. In other cases the name, the number of the house, and the occupation of the person are entered in our Inoculation Register. They are arranged alphabetically; and we went over our Attack Register and Death Register and checked the names. That is the way we did it.

Mr. G. Carmichael, I.C.S.

1 March 1899.

22,931. Did the Attack and Death Register contain any particulars beyond the actual names of persons who died?—It gives the streets and houses; and it also is supposed to say whether a man was inoculated or not. That, however, has not always been given.

22,932. Has it sometimes happened that nothing but the name of the person inoculated has been entered in the register of inoculated persons?—That has occurred in some cases.

22,933. In what proportion of cases did you find only the name?—I could not say.

22,934. Would the proportion be sufficiently large to seriously affect the results?—No, I do not think so. Most of those without names were the servants of gentlemen who were not living in the cantonment, and people in the cantonment.

22,935. When you say that you have only heard of two inoculated persons acquiring plague, I understand you to mean two who have come under your personal observation?—Yes.

22,936. But you know that a considerable number died of plague?—Yes. There was the case of a man who came to a village in Parasgad taluka. He had been twice inoculated and he died. He came from Dharwar.

22,937. The villages now infected are in the south portion of your district?—Yes, mostly on the south side.

22,938. Adjoining what district?—Adjoining Dharwar.

22,939. Do you attribute the infection of the talukas at present infected to infection from your own district or from another district?—Partly from our own, and and partly from other districts. There are a lot of natives from the Native States. We have part of Sangli State in the centre of the suburbs of the Municipality.

22,940. Do you think that in order to make plague measures effective, it is essential that you should have the people on your side?—I certainly think so.

22,941. Do the people generally in your district recognize the benefits of any particular measures that are taken to suppress plague?—I think they do now.

22,942. What particular measure do you think they recognize as being useful?—They evacuate the villages of their own accord when they find rats. They do not understand why they should clean their clothes, and disinfect their clothes. It is very difficult to make them understand that.

22,943. But they do understand that they should leave a plague infected site?—Yes. Rats were found in the village of Holihosur in December; the people went out for a whole month, and they had no plague case until, I suppose, they thought they were safe, and some of them went back. We are having a few cases there now.

22,944. (*The President.*) I think you expressed the opinion that early information of plague cases was very important?—I certainly think so.

22,945. Do you think it is of primary importance?—Yes.

22,946. Otherwise, the alternative which you mentioned to removing the people is of no benefit; you cannot find out imported cases?—No.

22,947. If you always had early information, you would always be able to deal sufficiently early with imported cases?—Yes.

22,948. And, therefore, all other measures would be unnecessary, according to your views?—Yes; but my point is, that you cannot get information in many of the cases because the people do not know.

22,949. Have you any suggestion to make by which early information could be obtained as a practical measure?—I do not think you can get it. Very often you cannot tell whether a village has been infected, because it is infected before deaths occur and before sickness occurs.

Mr. G. Carmichael, I.C.S.

1 March 1899.

22,950. Do you mean that you cannot know until it is very strongly infected?—It may be infected without your knowing it, without deaths occurring amongst human beings. It is there that the difficulty of giving the first information arises. That is why I think it is important to disinfect clothes.

22,951. Even if you did hear of the first case in a human subject, that might not be sufficiently early information, because the place may be already infected?—It is usually too late when we hear of the first case.

22,952. What do you think has happened in that village?—I cannot say. It is only shown that rats are dying there.

22,953. You base your opinion upon the fact that rats may have died there?—Yes.

22,954. With reference to the distribution of the villages in your district in which plague has occurred, you have already given us the numbers; have you noticed any relationship to the larger rivers? Are the villages which have been infected near the rivers?—We have one large river going across. I do not think the nearness of the village to the river has any connection with infection.

22,955. The largest number of cases has not occurred near the rivers?—We have one or two villages near the large rivers.

22,956. Of all the villages infected, do you think the larger number are villages on the banks or near the banks of rivers; or, on the other hand, do you think that the larger number of infected villages are distant from the rivers?—I should think the majority of the villages are distant.

22,957. (*Mr. Hewett.*) Do you hold the opinion that the site of a village may become infected?—I do not know whether it is the site; the infection is there, in animals, or in the floor.

22,958. The only method of getting information is to get it from the village Headman?—Yes.

22,959. Although he is living in the immediate area, he may, in reality, be just as ignorant of the first case of plague as the Collector at the headquarters of his district?—Yes.

22,960. It may be quite impossible for him to give first information?—Yes, to give information that will be in time.

22,961. Even if he ascertains the first case of plague, and the time of the year happens to be the rainy season, may it not, in some instances, take considerable time for the information to come to you by the speediest manner in which it could reach you?—I should think the Patel, in the first place, would turn the man out if he was a villager.

22,962. If the Patel went with the utmost speed, it is possible that he might have a considerable distance to go to the Mamlatdar, and it would be some days before he would hear of it?—He might be on the wrong side of the river.

22,963. Does it not happen every day during the rains that a report takes a long time to reach the Collector?—Yes.

22,964. (*The President.*) I think you were going to explain that the delay need not necessarily occur on that account, as the authorities in the village would know how to act from directions which they had previously received; do I understand that to be the case?—If the Patel thought it was a case of plague, indigenous or imported, the man would be put outside the village.

22,965. (*Mr. Cumine.*) I should like to ask you a question about the medical establishment of the district. You have at the Sadr Station a Civil Surgeon, who is purely a Government servant, have you not?—Yes.

22,966. Is there any other purely Government medical servant in the district—purely Government as opposed to Municipal or Local Board?—There is none.

22,967. In each taluka would there be more than one Municipal medical man, as a rule?—No.

22,968. His duties would be restricted to the chief town of the taluka?—Yes.

22,969. So that you may say that throughout the villages of the whole district there is no Government medical man at all?—No.

(Witness withdrew.)

Lieut. G. B. Kidd, I.S.C.

Lieut. G. B. Kidd, I.S.C., called and examined.

22,970. (*The President.*) You are Plague Officer at Belgaum?—At present.

22,971. How long have you been Plague Officer in Belgaum?—Since the 6th November of last year.

22,972. Is this the only experience you have had?—I was 11 months in Sholapur before I came here.

22,973. (*Mr. Cumine.*) Your work in this district lies amongst the villages?—Yes.

22,974. And in Sholapur did it lie amongst the villages?—In the city at first.

22,975. For how many months were you in the villages in Sholapur?—About eight.

22,976. At present how many plague-stricken villages have you to look after?—Only two.

22,977. What is approximately the largest number of villages you have had to look after in this district?—About 22.

22,978. Could you give us any idea of the length and breadth of the area they occupied?—About 150 square miles.

22,979. Were you able to pay complete attention to any one village?—I had my head-quarters at one village, and attended there personally, and visited villages within 5 miles radius of that, generally one a day.

22,980. With 22 villages you would be able to visit each village about once in three weeks?—I think once in 15 days.

22,981. What establishment have you under you at the present moment?—I have one Abkari Inspector and one Karkun.

22,982. When you evacuate a village and you have to go on to another village, whom do you leave to look after the evacuated village?—If I am supplied with a Karkun or any outside man I leave him in charge, otherwise I leave the schoolmaster or the Kulkarni or Patel, whichever I think best.

22,983. Do you generally have a special officer to spare to look after the evacuated village?—I did not; one man had four or five villages to look after.

22,984. Mr. Carmichael has told us that though the people go out without much pressure, they require constant watching to prevent their going back into the village site and getting themselves re-infected there. Is that your experience?—I dare say in the village four or five people might go back. In fact, in one village I have just given them permission to go back, but they are rather chary about it.

22,985. Are they villages which have had experience of plague before, or are they infected now for the first time?—Now for the first time.

22,986. Do you find it is easier, in the matter of evacuation, to deal with villages which contain a purely agricultural population than with villages which contain a commercial population?—It is easier with the agricultural population. I have only met with very few commercial people in the villages.

22,987. What are your views with regard to having the co-operation of the people with us in any plague measures we wish to get carried out?—Nothing can be done unless the people be got to work with the Government. Any attempt to force them to go to hospital or to segregate contacts only drives them to conceal cases, and escape to other places carrying the infection with them. The same result would follow the inoculation operations carried on, even with mild compulsion.

22,988. What are your views with regard to evacuation in the rainy season in this district? Have you any experience of it?—I went out just at the tail end of the rains. It only rained perhaps once or twice a week for a fortnight. In Sholapur taluka we turned them out in the middle of the rains. There the rains are not so excessive as they are here, I believe.

22,989. Do you think turning them out in the rains entails great hardship upon them?—It depends upon the extent of the rainfall. In Belgaum taluka, I think, it would be a great hardship, but it was not in Sholapur.

22,990. Did you find that in order to protect themselves against the rain they barricaded their huts and stopped ventilation so thoroughly as to reproduce almost the same conditions as obtained in their houses?—They tried to, of course, but I do not think they had that success in their huts which they always had in their houses.

22,991. Did you find that evacuation in the rains succeeded in stopping plague in eight or ten days?—In the only village which I evacuated during the rains plague did not stop till about 25 days.

22,992. Did you notice whether the exposure had any prejudicial effect upon the health of the young or the very old?—Not on the very young, but perhaps one or two old people died on account of the exposure.

22,993. To what extent do you think the people will protect themselves in the way of keeping out suspicious strangers? Are they on the alert to do that?—The majority of them do keep out strangers if the village is in an infected area, but, of course, some always get in.

22,994. Those are the relations of influential people, I suppose?—Yes.

22,995. When plague has got into a village in this way, do you think the people who have had previous experience of plague will evacuate a village entirely of their own accord?—They do the infected gali, but they do not the remainder of the village. They never go out of the galis in which no deaths have occurred of their own accord; at least, I have never found it so.

22,996. Have you noticed whether imported cases from Bombay seem not to infect the local people here?—No cases have come to my knowledge from Bombay.

22,997. Have you noticed what the interval is between the arrival of an imported case and some local person getting infected? Is it four or five days, or a month?—Generally three or four days.

22,998. Have you specific instances in your memory?—I am afraid I have not any special case which I could bring forward.

22,999. Have you noticed whether rats invariably die between the arrival of the imported case and the occurrence of the first local case, as though the imported case was unable to infect the local case directly, but had to do it through some medium?—I have not noticed that.

23,000. Have you any system of passes so that a man is not allowed to go from one village to another without getting a pass?—He has to get a pass from the Resident Plague Authority.

23,001. How far may he have to go to get that?—At the outside it would be 3 miles from the village, and it is probably only one, but he need not go so far as that, because the fields are divided up into sections and each section has a supervisor.

23,002. He has not to come to you to get it?—He cannot. My camp may be 15 miles away. The Resident Plague Authority would be one of the native Karkuns or an Abkari Inspector.

23,003. The standing order does not require him to come to you for a pass?—No.

23,004. You mention in your précis a case of infection being carried by grain. You say that at Mohol village many Banniahs had the plague: some Mangs stole their grain, and a few days after many Mangs got plague. Are you able to exclude the possibility of the Mangs having caught the plague themselves when they came to steal the grain?—I am afraid I have not down the date of the evacuation of the house. The house had been evacuated by the Banniahs. Of course, they might have caught it through going into an infected house.

23,005. Do not you think it is more likely that they caught it from the infected house rather than from the grain?—No, because, in the village I came to about 10 days ago, a Banniah had got the plague, and a woman who bought some grain from him got plague four days afterwards. The Banniah's daughter had died of plague, and I could not trace how this woman had got plague in any other way, as she was living in a hut at least 100 yards away from any other hut, and she had not been in the village for a month, and none of her relations had died of plague. The Banniah's daughter had died before the woman went to the house.

23,006. But might not that woman have gone to the house a few days before while the daughter was still alive?—Yes, that is possible. This Banniah was living in a hut, and he had all his stores outside the hut on a little verandah, and I do not think the woman who went to buy grain went into the hut: she would have stayed outside.

23,007. With regard to the comparative cleanliness of the people, what are the people that you think are the most liable to be attacked by plague?—There is no distinction, I think.

23,008. You mention that in two villages no Mahars were attacked, and that Maharwaras were not evacuated, although the villages were. But did not the Mahars live apart from the rest of the villagers?—In both those villages there is only a street between them. One was the high road about 50 yards, and the other was less than 10 yards.

23,009. The Mahars are considered impure by the natives, and are not allowed to enter the houses of the natives; is not that so?—Yes.

23,010. You speak in your précis of instances having come to your notice where people have stolen clothing from plague corpses and contracted the disease. Will you describe those to us?—Only two cases came clearly under my notice. The first was one in which the Mahars, who went to bury a corpse, were found with the clothing of the corpse in their hut. In the other case the man died of plague in a hut alone, and a Mahar stole his clothing.

23,011. I suppose, in order to steal the clothing, he had to go into the hut, had he not?—Yes, but only for a minute. I consider he caught the plague from the clothing.

23,012. Do you think it is dangerous for people after having evacuated a village to go and live too near it, and, if so, why?—In this cotton soil, when they are gathering their harvest, I have found two villages where the rats came out of the village and the people caught plague: in fact they moved their huts two or three times, and the rats followed them.

23,013. What makes you conclude that the rats moved?—Because I take it that the rats do not live in empty fields.

23,014. Were they house rats?—I did not actually see the rats myself.

23,015. Do you know whether they were house or field rats?—I do not know.

23,016. Have you noticed whether the villages infected this season are the same villages which were infected last season, that is, last rains?—I was not here during the last rains. I see from the Government "Gazette" that none of the villages I was working in in Sholapur have got plague this year.

23,017. Have you noticed any case where a village after having become perfectly free of plague has got attacked by plague again months afterwards, and, so far as could be traced, there has been no second infection, but apparently a recrudescence from the original germ in the village itself?—Not months afterwards—20 days afterwards.

23,018. (*The President.*) You have always traced another importation of plague in those cases which would account for the recrudescence?—Yes; 20 days was the longest interval between the two.

23,019. Have you any system of corpse inspection in your villages?—No.

23,020. Do you think it would be offensive to the people to have the corpses of their female relations examined? — Yes, I think it would be, especially among the pardah women.

Lieut. G. B. Kidd, I.S.C.
1 March 1899.

23,021. Would it be practicable to examine the corpses of such women?—It would be impossible, I think.

23,022. Have you had any experience?—I had not even seen them alive.

23,023. You are not allowed to see them?—I presume they do not allow one to see them when dead, as one is not allowed to see them when alive.

23,024. (*Mr. Hewett.*) When you say you have not seen them alive you mean that you have not been permitted to do so on account of the customs of the people?—Yes.

(Witness withdrew.)

Lieut.-Col. C. T. Peters I.M.S.

Lieut.-Col. C. T. Peters, I.M.S., called and examined.

23,025. (*The President.*) You are Acting Civil Surgeon in Belgaum?—Yes, and Acting Deputy Sanitary Commissioner.

23,026. How long have you been here?—Since February 1897.

23,027. Can you inform us what was done to guard against the importation of plague?—In consequence of the prevalence of plague in the City of Bombay arrangements were made so early as the 22nd January 1897 to inspect and report on the arrivals in Belgaum by rail, agreeably with Government orders, and the Municipality detailed the Medical Officer in charge of the Municipal Dispensary to do this duty, who was instructed to take any persons suffering from plague to the Civil Hospital for segregation and treatment, and the first case of plague was discovered on the 24th January 1897, a passenger from Bombay to Goa, who was detained at the Civil Hospital in the infectious ward (which is set apart for the treatment of cholera or smallpox cases in ordinary years), and was discharged cured on the 10th February 1897. The Collector of Belgaum issued orders to the Railway Police "to detain passengers at Belgaum reasonably suspected "of being infected with plague until they have been "medically examined under the orders of the Civil "Surgeon to whom such cases should be instantly "reported *direct* as they occur." By direction of the Surgeon-General a separate hut was built for the reception of plague cases by the Municipality in the Civil Hospital compound.

23,028. I want to understand how plague was introduced?—In the month of September 1897 a pensioned Naik returned from Sirur with the family of another pensioned Naik, who had died of plague in the Cantonment Bazar Sirur. According to his statement, they were segregated at Sirur from the 20th to 31st August 1897, and their clothing was boiled in the presence of the Medical Officer before they left the camp. However, on the 11th September one of the children got plague and died in the Cantonment Bazar. On the 22nd September another child sickened, and died on the 11th October, and the third on the 19th October. Shortly after, his neighbours, the Kakars, became infected in the Cantonment Bazar, where he kept a grain shop. On examining the Cantonment Death Register kept by the Cantonment Police, it appears that Jainabbee walad Silar, aged two years, died on the 7th September, the cause of death being put down under "other causes." On the 13th October 1897 another child named Gafur walad Silarbux, aged five years, died, the cause of death being put down as "fever"; and on the 21st October 1897 another child named Abdulrahman walad Silarbux died in the Native Infantry Lines Bazar, the cause of death being recorded as "fever" All these children, pensioned Naik Silarbux informed me, had glandular swellings. Thus it appears that the infected family arrived in Belgaum on the 3rd or 4th September 1897, and on the 7th September 1897 the first death had occurred.

23,029. It was an imported case which was not discovered promptly?—That is so.

23,030. And no discovery was made until a good number of cases had occurred?—That is so.

23,031. How do you account for the extension of the disease to the town of Belgaum?—In the town of Belgaum the first case of plague occurred in the family of a store lascar. The child was admitted into the Civil Hospital on the 22nd October 1897, and no doubt he had received the infection in the Cantonment. There were no further cases in the town until the 6th November 1897, when a Brahman gentleman arrived from Poona from an infected part of that city and was admitted into the Kanburgi Camp. He died there on the following morning. The first indigenous case occurred on the 23rd November 1897, when a Mahratta took ill. He was serving under a Marwari who had a shop in the Cantonment Bazar, and was found dead in the town. Shortly after his master's death, this man was infected and was removed to the Kanburgi Camp. So it appears to have come from the Cantonments. The Brahman gentleman from Poona was removed within a few hours after his arrival.

23,032. Of the several measures which you employed, which do you think are the most effective?—Evacuation, segregation, and disinfection, in the order named. In an infected locality the first thing to do would be to evacuate the place, then segregate those who had been taken out and disinfect them, their clothing, all their belongings and their houses.

23,033. Have you had much experience of evacuation?—I had nothing to do with villages. I have had only charge of camps in connection with my hospital, where hundreds of people were brought in from infected houses. Some of them were sick, and some of them were contacts, amongst whom very few cases of plague appeared afterwards.

23,034. You had nothing to do with the actual process of evacuation?—No.

23,035. How do you account for the beneficial results of evacuation?—As soon as the people are taken out into the fresh air, and removed from the infected places, the number of cases ceased altogether, or only one or two cases occurred amongst them. I remember in December 1897 a Brahman woman was confined. Her baby was 14 days old, and the question was whether she was to be removed to the health camp or not, a case having occurred in the family. Her husband went in charge of the sick child into the health camp, and the child died, but the husband remained alive. This poor woman was allowed to remain in her house, with her child and two attendants, that is to say, her sister-in-law and her husband's brother. Both the sister-in-law and the husband's brother got plague in the house. The brother died in the house and the sister-in-law died in my camp, where she was removed after her husband's death, along with this woman and her baby. A large number of people were taken away, but with the exception of the sick child, who died in hospital, there was no other case amongst them.

23,036. What are the conditions which account for the benefits of evacuation?—Principally fresh air and sunlight.

23,037. Have you had much experience of disinfection?—Yes. I have used nothing but disinfection in my hospital and the health camp.

23,038. Not in the town?—Not in the town.

23,039. In the second epidemic the measures which might have been desirable were somewhat obstructed by the heavy rains?—Yes.

23,040. What was the result?—At first the sick and contacts were segregated, but subsequently neither the cases nor the families were removed, because we had no more space after my segregation camp had become crowded.

23,041. At first you did remove them?—Yes, and then when we got overcrowded we could not remove them. The consequence was instead of only the person first attacked dying, three, four or five cases died in the

houses. I can only say that from hearsay; the people have told me that when they came to my camp. There was a large family of Pattawallas, Peons, in the different offices here. Only two of the brothers came to the camp and four other brothers perished in the house. After they were brought into my health camp, 13 in all, there was not a single case among them.

23,042. You think that because you could not sufficiently evacuate, the epidemic spread all through the town?—Yes. The way the epidemic spread through the town was this. A person got sick in one house. Perhaps the sick person and an attendant remained there, and all the rest went into a comparatively healthy locality; they carried the infection there and died there. Sometimes it was not the sick, but rats which went from one place to another.

23,043. How do you account for the benefit of evacuation if the rats move?—Evacuation alone is not efficacious, but must be accompanied with disinfection. If the people go back to their houses, they would get plague again unless the houses are thoroughly disinfected. That is why I believe disinfection measures should be strictly carried out.

23,044. Have you had any experience of disinfection?—In the case of the first village which was attacked in November, a place called Kagwad, I went over to it with the Collector. That was thoroughly disinfected, because I sent over large quantities of perchloride of mercury at the request of the Hospital Assistant. To this day there has not been another case of plague in that village. I think the last case of plague was somewhere about March, but I am speaking from memory. After the first epidemic was over the people were allowed to go back to their houses, and to this day there has not been another case.

23,045. How long was the interval?—The epidemic lasted from November 1897 to March 1898. There have been no cases since.

23,046. Have you charge of the Civil Jail?—Yes. I am Medical Visitor of the sub-jail.

23,047. Had you any plague there?—We had in November 1898. I think about the 16th November an under-trial prisoner was reported to have had fever. My Hospital Assistant had gone to see him and the next day he was better, and therefore he did not go that day to see him. The fact of the matter is this. As there is no Hospital Assistant now attached to the jail, the patients are usually sent to the Civil Hospital when their cases are supposed to be serious. But this man suddenly got worse and died about 9 o'clock in the evening, on the 17th November. The next morning the Hospital Assistant, on viewing the body, found plague glands. We at first thought that as he had just returned after giving evidence at Gokak he had brought the infection from there. I went to see Mr. Carmichael and he rode up on his bicycle much quicker than myself, and found on going into one of the rooms which was formerly used as the hospital, but which is now used as a godown for grain and other things, that there was a very offensive smell in that place. Accordingly, the next day he took a disinfecting party there himself, and on digging up the place a dead rat was found. I heard subsequently that about five days or a week before this man died there were dead rats found in the godown. The grain was removed from there. The man who got plague was cooking his meals in the room next to it. My own impression is that the man got the infection, as well as the whole jail, from those rats. Afterwards rats spread all over the place, in the kitchen and offices and all the wards.

23,048. Dead rats?—Some of them were dying; they were crawling about and hardly able to move.

23,049. You say this man was under trial?—Yes.

23,050. How long had he been in jail?—I forget now; the jailer will be able to give that information.

23,051. Do you know whether it was a fortnight or a week?—Within a week.

23,052. When was he admitted into the jail? Will you kindly find out exact particulars?—Yes. (Witness subsequently noted as follows:—He was admitted into the sub-jail as an under-trial prisoner on the 25th October 1898; was sent to Gokak for trial on the 2nd November 1898; and returned thence to the jail on the 12th November 1898. He had fever on the 16th, and died in the jail at 9.30 p.m. on the 17th November 1898.)

Lieut.-Col. C. T. Peters, I.M.S.

1 March 1899.

23,053. Do you think the rats may be infected by grain?—Yes.

23,054. Have you any observations which seem to support that view?—In the case of the pensioned Naik (Corporal) he was selling grain to sepoys and other people, who bought provisions from him. I believe the 26th Madras Infantry got it from him, because a child died in the Native Infantry Lines Bazar.

23,055. How do you know that there was no human conveyance; can you exclude that?—Of course there was human conveyance as well.

23,056. Have you any case in which you think there was clear evidence that the grain was so infected as to be able to produce plague?—No, I have no clear evidence.

23,057. Or with regard to grain bags?—No.

23,058. You have observed a difference in plague mortality at different periods of life?—Yes.

23,059. What do you say about that?—The only observations I have made chiefly are with regard to children under one year.

23,060. Is there any immunity or proneness with regard to plague at any period of life?—Children are more or less immune, either from plague attacks or fatal terminations.

23,061. Why do you say that?—In a place called Khanapur there were 38 deaths from plague and no deaths under four years of age, and only one child aged four years.

23,062. I suppose there is the normal number of children in this place?—I could not say that, but I presume that the proportion was the normal one. We always assume, under the vaccination figures, that about 32 children under one year are alive, out of the total births, viz., 40 per 1,000 of population.

23,063. You have no reason to suppose it was different here?—No. Again, in the village of Kagwad, there is no single child under one year of age who died of plague.

23,064. Were all these children vaccinated or not?—By the Vaccination Register we assume that about 32 per 1,000 of the population is available for vaccination and nearly three-quarters of them are vaccinated. I think it may have some protective influence.

23,065. Simply because the children under a certain age are not affected so much as older persons?—Yes.

23,066. With regard to rats, you place great importance upon the diffusion of plague by rats, do you not?—Yes.

23,067. Can you remember whether there were many diseased rats in the first epidemic of plague in Belgaum?—Not one was known when the epidemic first broke out; at least, I never heard of any.

23,068. Was there throughout the epidemic the same absence of dead rats, or was it most remarkable at some period in the epidemic?—Since May dead rats have been heard of, but not before; the first epidemic extended from October, 1897 to the end of April, 1898.

23,069. Therefore, throughout the first epidemic, there were, at any rate, not sufficient dead rats to attract attention?—That is so.

23,070. Nevertheless, plague was virulent?—Yes.

23,071. How does that bear upon your view of the great importance of the spread of plague by rats?—Families began to evacuate the town and went into the fields. Within a short time after they arrived there, they began to get dead rats in their huts.

23,072. Were there many cases of plague among the evacuated relatively to the number among the non-evacuated?—No.

23,073. (*Mr. Hewett.*) Do you consider that the jail was infected by means of rats?—That is my impression, because five days or a week before this prisoner died, I am told that dead or diseased rats were found.

Lieut.-Col. C. T. Peters, I.M.S.

1 March 1899.

23,074. Did you see any diseased rats?—I did not see any myself.

23,075. What number of people went away from Belgaum?—I have no figures.

23,076. Can you form any estimate?—It varied in different periods. I think that, about January 1898, only one quarter of the population remained in Belgaum.

23,077. How many people went away from the neighbourhood altogether?—I do not think that figure can be obtained.

23,078. Had you anything to do with the inoculation here?—No.

23,079. Have you seen the records of the inoculations here?—Yes.

23,080. Where are they?—Some are kept by the Municipality and some by the Cantonment authorities.

23,081. Who has them now?—I think they will be found in the proper places.

23,082. In the case of the people who were inoculated in December 1897 and January 1898, what facts were included in the register?—The names were given in the Cantonment Register, but the professions were not given.

23,083. Have you seen the books in which the records are contained?—I have seen the Town Register once and the Cantonment Register oftener.

23,084. Have you looked to see what facts are contained in those registers?—Yes; the names, age, residence, the profession of the man, and the date of inoculation. Those are the principal things recorded in the Municipal Records. I have already stated what are contained in the Cantonment Register.

23,085. Is the residence recorded in the case of those people who were inoculated in December 1897 and January 1898?—In a general way.

23,086. What do you mean by residence in a general way?—In the town the street has been entered, and sometimes the number of the house also, so that you can find out exactly where they came from.

23,087. Is the place of residence recorded in every instance in the City Register?—I could not say that; I have not examined the books so carefully. In the cantonment some names were not put down at all, but it was simply stated that a certificate was given to a sepoy of the 26th Madras Infantry.

23,088. Can you state the number of those inoculated in the cantonment and in the Municipality?—No. I should like to state that in one case a woman left the camp with a certificate of Major Minchin that she had been inoculated, and it was found on inquiry that her name was not on the register. In other instances, I have recently found that transport mule drivers and dooly-bearers, of the Commissariat, who had been inoculated, are not recorded in the Cantonment Registers, that is to say, they had not been entered up to that date.

23,089. When were they inoculated last year?—Those papers I saw were dated September, October, and November, 1898.

23,090. And they have not been entered yet?—Probably they have by this time. I got them in the Cantonment Magistrate's office, when we were trying to fill up inoculation figures and verify the number of deaths.

23,091. How long after inoculation?—Only last month—February.

23,092. (*Mr. Cumine.*) What was the approximate number of those people who had been omitted in this way in the register at the time of inoculation? 5 or 500?—I could not say.

23,093. (*The President.*) How many do you know?—In the nominal roll of inoculated persons in the Belgaum Cantonment who have got plague, I have a number of names which have been recorded who came to the Civil Hospital after having plague, and from inquiries I found out that they had been inoculated, but the names cannot be found in the Inoculation Register.

23,094. Can you tell us how many?—46.

23,095. (*Mr. Hewett.*) How many people came into the Civil Hospital suffering from plague after having been inoculated?—11 cases from the town and 49 from the cantonment—altogether 60.

23,096. In how many of those cases were you unable to find a record of inoculation in the registers?—Only three have been identified in the Cantonment out of 49.

23,097. Forty-six people stated they had been inoculated, but you could not find out whether they had or had not been from the register?—That is so.

23,098. How many did you identify in the town?—3 were identified out of 11.

23,099. Three persons said they were inoculated, but you could not discover their names in the town register?—Yes. One came from Gadag.

23,100. The remaining two came from the town?—Yes.

23,101. Did you have any cases of inoculated persons getting plague who were not treated for plague? You have 60 down here?—These 60 names were sent to me by the Chairman of the Municipality; they have been verified cases.

23,102. You do not put them forward?—No; I only put the hospital cases forward.

23,103. (*The President.*) I believe you can give us a case in which plague occurred twice in the same person?—Yes. A boy named Miran Sahib, father's name Hussan, was admitted to hospital on the 8th November 1897. He had several glandular swellings, and his temperature, at one time, went up to 105·4. The high temperature lasted for eight days, and after that it went down, but the buboes took a long time to heal. He was discharged cured on the 28th of December 1897.

23,104. Did you ascertain how he acquired plague?—Yes. Major Minchin told me about this case. The boy was the son of Major Minchin's bhisti (water carrier). When he went to search the house, he found that the child was being secreted by the back door. It was taken up and was found with fever, and was sent to the Civil Hospital for treatment. The rest of the family were sent for segregation to the segregation camp of the Cantonment.

23,105. There had been already a case of plague in the house?—Yes.

23,106. When did you see this person again?—A note from the Hospital Assistant on plague duty in the Cantonment Bazar states that the child had been ill for seven days, as a hidden case, with fever and a bubo, on the 22nd of February 1899. It was a hidden case the second time also. He came over to the Civil Hospital on the 22nd of February 1899, with a temperature of 102·4, which went up to 102·6 on the 23rd. Then on the 24th and 25th, it gradually came down till on the 25th it became normal, and the temperature now continues normal. He has a swelling on the same groin as before; on the previous occasion he had also a swelling on the neck. This boy is still in hospital.

23,107. Was this boy inoculated?—No.

23,108. You wish to put in a statement to show that in houses containing both inoculated and non-inoculated persons some of the inoculated acquired plague, while some of the non-inoculated escaped. How many cases are there?—Four. I put those cases in, as follows:—

OCCURRENCES of PLAGUE in HOUSES INHABITED by PERSONS INOCULATED AGAINST the PLAGUE.

Full Address.	Names, Sexes, and Ages of the *inoculated* Persons who were living in the House on the Date of Attack, with the Dates of their Inoculation. Name, Sex, Age of the Attacked, if he is amongst the *inoculated*; Date of Onset of Disease, Symptoms, Issue.	Names, Sexes, and Ages of the *un-inoculated* Persons who were living in the same House on the Date of Attack. Name, Sex, Age of the Attacked, if he is amongst the *un-inoculated*; Date of Onset of Disease, Symptoms, Issue.
	HOUSE No. 1.	
Jalgar Gali, Khadakwada	Gangubai F. Vithoba. Female. Age 10 years. Not attacked. Sorabai K. Vithoba. Female. Age 30 years. Inoculated on the 8th January, 1898. Date of onset of disease, on or about the 19th January, 1898. Fever temp. 100°. Pulse 96, full and strong. Glandular swelling about the size of a large lemon behind the left ear; only one, which did not suppurate. Admitted 22nd January, 1898, discharged cured, 10th February, 1898.	Govinda F. Vithoba. Male child. Age 3 years. Not attacked.
	HOUSE No. 2.	
Cantonment, Belgaum, Madras gali.	Francis F. Rayapa.* Agnes K. Francis Rayapa.* Francis F. Francis Raya. Inoculated 8th January, 1898. Dose $\frac{1}{2}$ cc. Chowriapa Raya. 8th January, 1898. Dose 1 cc. †Mari F. Raya. 8th January, 1898. Dose 2·10 cc. Arakswamo F. Raya. 8th January, 1898, Dose 1·5 cc.	Yesu Manwell F. Francis Raya. Baby. Age 8 months.
	HOUSE No. 3.	
Konwalgali, Town of Belgaum	Tulsabai K. Narayan. Female. Age 40. Inoculated 10th January, 1898. Got ill on the 3rd February, 1898. Noticed a swelling in right groin, after being ill, accompanied with pneumonia. When brought to hospital on the 6th February, 1898, was rather delirious. Tongue dry and brown. Bowels said to be not moved for three days. Discharged cured, on the 3rd April, 1898.	Krishnabai kom Hanmant Female. Age 20 years. Not attacked.
	HOUSE No. 4.	
Aditwar Pet, House No. (not known).	Adiwewa K. Baseteppa. Female. Age 35. Got fever 13 days after inoculation. Saw glandular swelling in left inguinal region after three days of fever. Only one—was opened on the 18th January, 1898. Discharged cured, on the 7th February, 1898.	Shivalingawa K. Timapa. Female. Age 75. Pitrawa K. Mallapa Gonje. Female. Age 35. None attacked.

* Names cannot be found in register: state that they were inoculated at the Hindalgi Camp.
† Mari was admitted on the 29th August, 1898, with a swelling in right groin. Discharged cured on the 15th September, 1898.

23,109. In the case of house No. 1, what was the age of the person who escaped?—Three years.

23,110. This is a person who was not inoculated?—Yes.

23,111. What was the age of the non-inoculated person in house No. 2?—Six or eight months old.

23,112. In the third house there were two persons?—Yes; one was a mother and the other the daughter; the mother, aged 40, was inoculated, and the daughter, aged 20, was not. The latter did not get plague.

23,113. What about the fourth house?—In the fourth house there were two persons who were not attacked; the first was 75 years old, and the other was 35 years old. Neither of them was inoculated. There was another person who was also 35 years old, who was inoculated, and got fever 13 days after inoculation, with glandular swellings. She was discharged cured.

23,114. In the first two houses and in one instance in the fourth, the persons were, I think, on account of their age, not very liable to plague?—That is so.

23,115. In the households where these cases occurred, there were other cases I think?—I cannot say that. That information is not supplied to us by the Supervisors who send them over.

(Witness withdrew.)

Mr. G. UCHGAONKAR called and examined.

Mr. G. Uchgaonkar.

(Evidence translated).

23,116. (*The President.*) You are Chairman of the Municipality of Belgaum?—Yes.

23,117. (*Mr. Hewett.*) Is there any system of registration of deaths here?—Yes.

23,118. Is there a byelaw requiring a householder to register every death that occurs in the house?—Yes.

23,119. Is that byelaw carefully observed?—Yes.

23,120. Do you think that cases of death ever fail to be registered?—All deaths have probably been duly registered.

23,121. Do you think that cases of death escaped registration at times or not?—I do not think so.

Mr. G. Uchgaonkar.

1 March 1899.

23,122. What is the population of Belgaum?—27,952 according to the census of 1891.

23,123. Is the population larger now than it was then?—The present population is 18,948.

23,124. When did the first epidemic of plague begin?—The outbreak first commenced in October 1897. In April and May 1898 the number decreased, and the epidemic finally stopped in June 1898.

23,125. When did the second epidemic begin and terminate?—It began in July 1898; it is not yet ended.

23,126. Are casual cases happening at the present time?—There was one case to-day.

23,127. Do you put in a table showing the number of cases from October 1897 to the end of 1898?—Yes.

Weeks.	1897.						1898.

23,128. Do you know the total number of cases in January of this year?—The number of cases in January 1899 is:—

Attacks.	Deaths.
14	13

23,129. What were the main measures adopted in the first epidemic?—The measures adopted to suppress the epidemic were as follows:—

(1.) The first and foremost was the segregation of the sick and of their families in hospitals and quarantine camps. This was rigorously enforced.

(2.) The second—disinfection of the infected area—was effected by removal of the roof or part of it, and by squirting a solution of carbolic acid (1 in 20), or perchloride of mercury (1 in 1,000), by means of garden syringes over the floor and all the interior walls and roof. Much light and air were let in.

(3.) All the clothes and beddings of infected persons were invariably burnt at his death or recovery, and the clothes of the rest of the family were soaked in a solution of carbolic acid or perchloride of mercury.

(4.) Families were not allowed to return to their houses until the houses had been thoroughly disinfected, and until at least 10 days had elapsed from the time any of the members of the family were exposed to some kind of infection, and until all their clothes had been disinfected in the presence of persons specially appointed for the purpose.

(5.) When a house was once vacated it was rarely allowed to be reoccupied within a fortnight or so.

(6.) Houses in the immediate neighbourhood of infected houses were treated as suspected, the inmates were segregated, and the buildings disinfected.

(7.) Houses where rats were found dead, apparently by plague, were treated as infected places, and were disinfected in the same way.

(8.) Thorough cleaning up of all the houses infected by plague and dead rats ultimately led to the wholesale disinfection of all the buildings situated within the Municipal limits.

(9.) People were induced and encouraged to erect their own sheds in fields, and to remove themselves there.

(10.) Number of huts were erected on the fort glacis for the convenience of those who were unable to have their own huts.

(11.) Until the setting in of the rains the weekly Saturday bazar was held outside the town.

(12.) Re-occupation of houses was complete by the end of June 1898.

23,130. Did you superintend the work of inoculation in the town?—I did not.

23,131. Can you say when inoculation in the town began?—On the 26th December 1897.

23,132. What privileges were given to the inoculated?—These persons appeared themselves for inoculation on the assurance given to them that no inoculated person would be liable to be removed to hospital or segregation camp against his wish. This privilege was subsequently withdrawn, and the following special rules were given to persons inoculated:—"A person "inoculated before January 16th is not liable to "segregation, even if a case of plague occur in the "house in which he is living, unless he himself gets "plague. In that case he will be sent to the Civil "Hospital, if he prefers, instead of to the Kanburgi "Hospital. Persons inoculated after January 15th "will still be liable to segregation in case plague occurs "in their houses." The result of the withdrawal of the privileges was to put almost a complete check to further progress of inoculation. The per-centage of inoculated persons over the population was 12·2.

23,133. Do you put in a statement showing the number of persons inoculated week by week?—Yes. It is as follows:—

STATEMENT showing the NUMBER of PERSONS INOCULATING, week by week at different places from 26th December 1897 to 31st December 1898, at the BELGAUM MUNICIPAL OFFICE and OTHER INOCULATION STATIONS.

Grand total	3,447						

23,134. How many cases of plague, and how many deaths occurred among the inoculated persons?—There were 62 attacks and 33 deaths.

Mr. G. Uchgaonkar.

1 March 1899.

23,135. Do you think that the people were very much afraid during the first epidemic?—The people got frightened, partly on account of the Government measures and partly on account of the epidemic.

23,136. Did they report the number of cases accurately in the first epidemic?—They were not reported accurately.

23,137. Were the cases accurately reported in the second epidemic?—They gave information.

23,138. Why did they do that in the second epidemic?—During the second epidemic the patients, as well as the people, were allowed to remain in their houses, and therefore they quite accurately gave information and they had no fear.

23,139. Do you think that during the first epidemic many persons ran away from Belgaum suffering from plague or while they were in the incubation period of plague?—I think persons with sickness must have gone out of Belgaum.

23,140. Did they do so also in the second epidemic?—No.

23,141. Did the people here show any objection to being treated with European medicines?—Some illiterate persons have objected to Europeon medicines, and said they would prefer native treatment.

23,142. Who prepared the statement showing the names of inoculated persons who had attacks of plague, but subsequently recovered, and also the list showing those inoculated persons who died?—I prepared this statement.

23,143. Will you put it in?—Yes.

LIST showing the NAMES of INOCULATED PERSONS who had ATTACKS of PLAGUE but subsequently RECOVERED.

Serial No.	Street.	House No.	Name in Full.	Age.	Caste.	Occupation.	Number and Date of Inoculation.		Number and Date of Attack.		Remarks.

23,144. Did you prepare the statement* which shows the social position and name of the inoculated people?—I did not. My head clerk prepared it, not by my orders, but at the direction of Dr. Boyce.

23,145. What is the meaning of this statement which is appended to the précis of your evidence headed, "Statement* showing instances where the whole "families and the majority of members of families "have died of plague within the limits of the Belgaum "Municipality?"—In that statement I show the largest number of persons dying in a family.

23,146. In some instances three out of 14 died; that does not show that the majority of the family died of plague?—That is so.

23,147. Had you anything to do with the preparation of the report* on inoculation which has been separately sent to the Commission; do you know who prepared it?—I had nothing whatever to do with that report; it was drafted by my head clerk.

23,148. When was the census taken that gave the population as 37,800?—During the months of October and November 1897.

23,149. Was it a census of the people resident in the town, or also of the people living in huts outside the town?—Only of persons living in the town.

23,150. How many, do you think, are residents in huts outside the town?—No complete census has been taken of the people living in the huts. Some of them lived in huts outside the Municipal limits.

23,151. Can you estimate the number of townspeople who are at the present moment living in huts outside the town?—Nearly 10,000.

23,152. (*Mr. Cumine.*) I do not understand how you reconcile these inoculation figures in paragraph 14 of your précis (which is as follows:—"14. The work of "inoculation in the native town of Belgaum com-"menced on the 26th of December 1897, and in "1 month and 19 days 2,094 persons were inoculated, "and from 23rd July 1898 to 17th November 1898 "the number of persons inoculated was 1,344; thus "the number of persons inoculated was 3,438,") with those in the table which you have put in?—I cannot give any explanation about the inoculation figures.

23,153. Which may I take as correct?—The figures in the table are correct.

23,154. (*The President.*) What is the intention of the table in your précis from page 10 to page 29, headed "Statement* showing instances where the whole "families and majority of members of families have "died of the plague?"—My intention was to show how many cases occurred in each house, and how many of those cases occurred in one day, and how many in each house which was disinfected.

23,155. What conclusions do you draw from this table?—I think there is no benefit whatever from disinfection.

23,156. In some houses there were many more deaths than in other houses; can you explain the difference?—I cannot explain that.

* Not printed with the Proceedings of the Commission.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Collector's Office, Belgaum.

FIFTY-NINTH DAY.

Thursday, 2nd March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Major A. V. ANDERSON, I.M.S., called and examined.

Major A. V. Anderson, I.M.S.

2 March 1899.

23,157. (*The President.*) You are in the Indian Medical Service?—Yes.

23,158. What are your medical qualifications?—M.B.C.M., Aberdeen.

23,159. You have had a good deal of experience of the plague in the Dharwar district?—In Dharwar district for the last three months.

23,160. In which taluka?—In the Navalgund taluka, and the Nargund-petta.

23,161. How many villages are contained in that area?—53 belonging to the British Government.

23,162. And those which are not British?—They belong to the Native State. I have no charge of Native State villages.

23,163. You carried out evacuation more or less completely?—Yes, the following is a general statement of the plague work carried out:—

I began plague operations in Dharwar district on 5th December 1898, and was placed in charge of Navalgund taluka, west of the Benni Halla and Nargund Pettas, an area of about 30 miles by 10, which comprised 53 villages with a total population of between 50,000 and 60,000. To work this district in which were, from first to last, 23 plague infected villages, I had a subordinate staff of one plague karkun, two Circle Inspectors, two vaccinators, and one office clerk. In order to ascertain how many villages were actually infected, I placed one Circle Inspector in charge of the uninfected villages of Navalgund, and the two vaccinators in charge of the uninfected villages of Nargund. The number of villages in charge of each being from 8 to 10, with orders to fill in a special report form with regard to each village. These men visited one, two, and sometimes three villages each day, and as soon as they had done all in their charge they began over again, so that I had frequent and definite information regarding the uninfected villages. The plague karkun I placed in charge of the infected villages of the Navalgund and the other Circle Inspector of those in Nargund. In addition I had four policemen on plague duty, two in Nargund and two with my camp, but I had no occasion to use them for plague work. The people at each infected village were ordered to vacate the village and go into huts within three days. A general order for evacuation had already been issued, but as will be seen from the detailed report of each village, some took a month to evacuate, and even after definite orders were issued, one village took 12 days. Later, however, evacuation was always effected with in three days. A month after complete evacuation the people were allowed to return to the village to open up the roofs of the houses.

In this district, fortunately, the houses with few exceptions are single storeyed, the roofs consisting of bamboos laid on beams and covered with earth to a depth of one foot. The roof was opened by removing the earth and lifting up the bamboos, the whole length of each room for a width of two feet. After all the roofs in the village had been thus opened, the doors were opened and the houses swept out, the doors lifted off their hinges and left open, thus securing thorough ventilation.

The number of cases for the week ending 10th December was 191; for the week ending 17th December, 145; for the week ending 24th December, 172; for the week ending 30th December, 135; for the week ending 6th January, 117; for the week ending 13th January, 119; for the week ending 20th January, 60; for the week ending 27th January, 59; for the week ending 3rd February, 33; for the week ending 10th February, 31; for the week ending 17th February, 28; for the week ending 24th February (report not made up when I left the district on 28th February 1899).

The total number of villages was 26, with a population numbering 34,669.

The first village reoccupied was Talimorab, population 633, which reported plague on 27th November 1898; was totally vacated on 12th December; last case occurred 20th January; began to be opened up 9th January; readmitted 2nd February.

The next village reoccupied was Javur, population 858. Plague first reported 26th November; totally vacated on 7th December; last case reported on 2nd January; began to be opened up 14th January; reoccupied on 14th February 1899.

Hanasi was next reoccupied, population 1,097. Plague first reported 27th October; vacated 29th November; last case occurred 17th December; began to be opened up 17th December; reoccupied 16th February 1899.

These plague measures have so far entailed no public expenditure, all work being done by the villagers themselves.

23,164. Can you divide the villages into any groups?—In my précis of evidence I divide them into three groups.

23,165. What groups?—These villages might be divided into three classes,—

1. Those infected, while evacuation was not in practice, and concealment of the outbreak was kept up as long as possible.
2. Those infected at the beginning of December, when evacuation was carried out against the wish of the people and when concealment was still practised.
3. Those infected when evacuation was in full operation, and was not opposed by the villagers, and when systematic means were adopted for ascertaining the outbreak of plague on its first appearance in each village.

In the 1st class, I would include Morab, Hanasi, Javur, Yamanur.

In the 2nd class, Shirur, Talimorab, Amargol, and Nargund.

In the 3rd class, the remaining thirteen villages, viz., Padesur, Arekurhatti, Kálvád, Tirlápur, Shirkol, Gumgol, Karlvad, Hal, Rasugal, Jagapur, Kalkeri, Kurlgeri, and Banhatti.

Major A. V. Anderson, I.M.S.

2 March 1899.

23,166. You give examples of the results in the villages which you have grouped in each of these classes, do you not?—Yes.

23,167. Will you classify these results in tabular form? — The following table gives the required information:—

No.	Name of Village.	Population.	Date of First Case.	Date of Commencement of Evacuation.	Date of Completion of Evacuation.	Date of last Case.	Number of Cases between Dates entered in 4 and 6.	Number of Cases between Dates entered in 6 & 7 for each Period of 10 Days after Evacuation was completed.		Remarks.
1.	2.	3.	4.	5.	6	7.	8.	9.		10.
1	Hanasi	1,097	27.10.98	22.11.98	29.11.98	18.12.98	224	A. 15	B. 1	A.—Cases occurring within 10 days after evacuation. B.—Number of cases occurring after 10 days in camp.
2	Yamanur	984	27.10.98	13.11.98	20.12.98	12.1.99	159	A. 8	B. 11	
3	Morab	4,146	30.10.98	27.11.08	18.12.98	1.2.99	607	A. 22	B. 23	
4	Javur	858	6.11.98	27.11.98	7.12.98	3.1.99	83	A. 17	B. 10

Talimorab re-occupied 2.2.99. Javur re-occupied 14.2.99. Hanasi re-occupied 16.2.99.

23,168. Will you kindly state what opinion you have formed as to the results of evacuation?—I think evacuation has been very successful in the Dharwar district in the part of which I have been in charge.

23,169. What has been the general result of your experience?—The benefit of prompt evacuation of the infected site consists not only in lessening the severity of the outbreak in each individual village, but in lessening the tendency to spread throughout the other villages of the district, no new villages having been infected since the 6th January; while before active measures were undertaken the disease was spreading rapidly. The number of cases would undoubtedly have been fewer had it been possible to entirely prevent people from visiting the village site and surreptitiously breaking the seals and entering their houses.

23,170. The operation of evacuation had not, in all cases, a fair chance, had it?—No, it had not.

23,171. What was the nature of the difficulties which you had to encounter which probably made the results less beneficial than they otherwise might have been?—The people were very prone to return to the village to remove articles of furniture to their huts in the field, and as the staff at my disposal was limited, I could only check them by examining the seals on the houses.

23,172. Had you a sufficient staff to carry on all the operations of cleansing and disinfection and evacuation?—The cleansing had to be done by the people themselves entirely, I had no actual cleansing staff.

23,173. That also operated injuriously?—Yes.

23,174. In what way?—Because the people had to be allowed into the village to open the roofs of their houses, and while doing so they entered their houses, and were exposed to the danger of the infected site. If they had not done this work within the houses, then this cause of infection among a certain number would not have existed.

23,175. In carrying out evacuation in the most beneficial manner what conditions do you consider to be requisite?—My system in the Dharwar district has been to remove the roofs. I may as well explain that the houses there are one storey houses with bamboo roofs laid on beams. Over the bamboo they have a covering of earth to a depth of about 1 foot. I caused the earth to be removed from the roof the whole length of each room, and for a width of about 2 feet. I then lifted up the bamboos, which exposed an opening of about 2 feet by the whole length of the room, to light and air. When this had been done in every room in a village, I then opened the doors, took them off their hinges and removed them and left them open for a few days. I then allowed the people to return.

23,176. In obtaining the best results, I presume it is very necessary to get early information?—Yes.

23,177. In your treatment of plague cases, you, I suppose, draw some distinction between the requirements where there are only imported cases, as contrasted with the requirements where there are actually indigenous cases?—Yes.

23,178. Would you state what you think are the differences which are required?—In dealing with an imported case of plague, if we remove it before it has infected the locality to an uninhabited and sanitary area, and disinfect all articles likely to hold the infection, we destroy the originating cause of the plague outbreak. On the other hand the removal of an indigenous case is merely removing the sign, or symptom, of the already existing disease in the infected locality, and disinfection of the house, and its surroundings, even if done effectively and at once, does not necessarily destroy the existing disease, as, during the incubation

period of the first case, the disease has already spread we know not how far or in what direction.

23,179. And, therefore, in this latter instance, you recommend, as far as you can, complete evacuation?—Complete evacuation of the infected locality.

23,180. What was the general sanitary condition of the houses that you are now referring to?—Very bad. The people keep their cattle in the dwelling-house in all these villages in the Dharwar district.

23,181. What defects in connection with the sanitary conditions do you think operated most deleteriously in regard to plague? Was there any special defect?—I should think that this habit of keeping cattle in the house is the greatest sanitary difficulty in this district.

23,182. How does that operate with regard to plague?—Because there is always a large amount of organic matter on the floors of the houses.

23,183. How do you think that operates? Why should the large quantity of organic matter have a bad effect?—The filthy condition of the houses favours the spread of the disease.

23,184. Are the means of lighting sufficient or defective?—Very defective.

23,185. Is the ventilation and the fresh air supply to the inhabitants of the houses also very bad?—Yes, the ventilation is also very bad.

23,186. The presence of the cattle in the houses is then deleterious, in that it reduces the pure air, especially if the ventilation is very bad?—Yes.

23,187. What opinions have you formed as to the value of disinfection?—I think the disinfection of personal clothing is useful and it should always be carried out if possible; but the actual disinfection of houses, in my experience, I have found to be impracticable.

23,188. You could not carry it out?—No.

23,189. Why?—Because it would require a very large staff to work over such an extensive area as we had in the Dharwar district, and disinfection requires very skilled and constant supervision. Each individual gang of coolies must have a skilled and thoroughly reliable supervisor, who perfectly understands what we are trying to do by disinfection; and that is extremely difficult to get in this country.

23,190. Have you any cases that came under your observation in which disinfection was satisfactorily carried out?—No, not under my own observation. My opinion as to when disinfection of a house proves successful or not is when the people are taken out, and the house disinfected, and the people re-admitted at once.

23,191. You have had experience of that?—That is my idea of what disinfection ought to do. As soon as the disinfection is finished, the people should be re-admitted into the house immediately, and not kept out for 10 days or a month, because if disinfection destroys the germ, it destroys it at once.

23,192. You think that disinfection does not operate in that way at present?—No, the corrosive sublimate should destroy the germ if it is there.

23,193. You mean if disinfection is successful, that should be the result?—The people should be re-admitted and there should be no further case.

23,194. Have you any facts which show that that did occur?—Our experience in Igatpuri was against that.

23,195. I understand you mean if disinfection is a satisfactory measure it ought to operate in such a way that the people can return to their houses as soon as it is finished. It may be a few hours afterwards?—Yes.

23,196. I understand you have cases in which that did not occur?—Yes. Plague broke out in Igatpuri of the Nasik district in August 1897. At that time the theory of disinfecting the house, its inhabitants and their belongings, and allowing them to re-occupy the house at once was in favour, and as the rainfall at Igatpuri is extremely heavy it was impossible to vacate the village, population 4,000. A disinfecting party under an Assistant Surgeon, who had been working at disinfection work in Bombay, was obtained at once, and thorough disinfection with corrosive sublimate solution was carried on. After some time, as no good results appeared, I tested the solution used by the working party, and found that by the mistake of a decimal point the Assistant Surgeon in charge had been making up his solution 10 times too weak. I mention this to show that even if you have a good man in charge, such mistakes occur in working with a disinfectant. From that time the regulation 1 in 1,000 was used, but I cannot say with any better result. Igatpuri is a railway town, and the railway authorities having provided a large number of empty waggons all railway employés were moved into these with most satisfactory results. I may instance the case of two chawls, one inhabited by railway police and one by railway labourers; each of these had been disinfected four or five times and still cases occurred, when the inhabitants were moved into waggons, and no other case occurred amongst them.

23,197. With regard to the towns or villages which you evacuated what has been the population?—In the Dharwar district it varied from over 9,000 in Nargund to a small village of 300.

23,198. What was the largest town in your experience?—Ahmednagar or Sholapur, which are both of the same size, with a population of 60,000.

23,199. Which was the largest town in which you found complete evacuation could be effected?—I should think up to about 60,000 or 70,000.

23,200. Have you experience of other large towns?—I have no experience of anything over. I have been to Ahmednagar and Sholapur.

23,201. Was complete evacuation carried out in these two towns promptly or gradually?—Gradually, particularly in Sholapur. The disease obtained a strong hold of Sholapur before evacuation was carried out. In Ahmednagar on the other hand, the town was more quickly evacuated.

23,202. Does gradual evacuation act just as well as prompt evacuation?—No. My idea is that the people are still exposed to contagion—that the contagion spreads through an evacuated area, but it takes time to spread, and where we have slow evacuation the results are not as definitely beneficial as where we have prompt evacuation.

23,203. In this large place which you speak of, would it have been possible to have effected prompt evacuation?—No, I think not.

23,204. In a place of such a size that rapid evacuation is impossible, is evacuation by instalments, in your opinion, the best measure you can adopt?—In my opinion it is the best measure to adopt.

23,205. Even although it is not altogether satisfactory?—Yes.

23,206. What is the result of your consideration, founded upon experience, of the means by which plague is conveyed from one place to another?—By human intercourse mainly—by clothing. I find that in towns or villages at a distances of several miles from each other, the disease was invariably introduced by intercourse, either by persons suffering from plague or persons themselves in good health coming from an infected locality. My opinion with regard to this is that they carry the infection in their kit or clothing. When an uninfected person, I mean a man who is not suffering from disease, infects a locality, it is by his clothing and not by his person.

23,207. Have you any clear instance of that kind of infection?—In many instances which I have investigated, we find a distinct history of the introduction of the disease by human intercourse. In most places, as in Kurla, Bassein, Chembur, Trombay, Malad, Chinchni, Thana, Bhiwandi, Bhayndar, &c., we have a history of persons coming sick from an infected locality, or falling sick a day or two after their arrival prior to the occurrence of local cases. In other instances we find the disease introduced by persons themselves in good health coming from an infected locality. In Agashi the first local case occurred in the person of a Shimpi woman, to whose house some friends from Bombay had come to live. None of these Bombay people were sick or were afterwards attacked. In Kelwa also the first local cases occurred in the person of two Shimpis to whose house some Shimpis from Bombay had come five days before. These Bombay people were in good health, and after staying three days returned to Bombay. In both the above instances rats died in the houses after the arrival of the people from Bombay, and before the persons living in the house were attacked. It would appear that rats are extremely susceptible to the disease, have a short incubation period, and propagate the disease

Major A. V. Anderson, I.M.S.

2 March 1899.

locally. It is improbable that they intensify the poison, as in Mahim rats died in at least three different houses and no local cases occurred in the town. At Versova a striking instance of the disease being carried by an apparently healthy person occurred. The first imported case at Versova occurred on 30th January in the person of a Brahman who came sick from Bombay. The Brahman schoolmaster of Versova visited this man while he was sick, and attended his funeral on 31st January. The schoolmaster lived in the village Talati's house. On the 2nd February the Talati's nephew, who lived in this house, was attacked by plague, while the schoolmaster himself was not attacked till the 5th of February. In Marol also the first case occurred in a house to which a number of people had come from Bombay to attend a wedding. These people were in good health, and after staying some days they returned to Bombay in good health. Here also rats died in the house after the arrival of the Bombay people and before the first human occupant was attacked. Again in the village of Madhan, an isolated case occurred prior to the outbreak there, in the person of a man to whose house a man from Bombay had come to live. Four or five days after the man's arrival rats died in the house, and the people moved out into sheds. A day or two afterwards the local occupant of the house was attacked and died, while the Bombay man escaped. In Jegapur, of the Dharwar district, a man went to visit his brother's wife, who was suffering from plague at Shelawdi, nine miles distant. Two or three days after his return rats died in his house, and three days after his daughter was attacked by plague and died. Rats also died in the adjoining houses shortly after the girl fell sick, and 29 cases occurred in the village which was promptly vacated.

23,208. In addition to the conveyance by articles belonging to human beings, what other means are there?—Within inhabited areas, and in towns or villages in close proximity to one another, the disease was often spread by rats. This was well seen in the Bandra group of villages—Bandra, Pali, Chuim, Danda, Santa Cruz, and Joo, and also in the infection of old Kurla from new Kurla—where in every case the death of rats preceded attacks among the people.

23,209. You refer to a group of villages where you yourself made inquiries?—Yes, it is my own personal investigation on the spot.

23,210. How long before a case occurred had dead rats been found?—In Bandra, which is practically a suburb of Bombay, the first local case occurred on 3rd December in a house in which dead rats had been found about one week before, and the disease at once spread in this locality. On the same date another local case occurred in another part of the town in a house where no rats had died. The disease did not spread in this locality, and it is possible that the infection had been caught elsewhere. In Pali dead rats were seen on the 6th or 7th of January, and the first case occurred on 13th January. In Chuim rats died in the beginning of February, and the first case occurred on 9th of February, although it was not reported till the 12th February. In Danda in the same way dead rats were found in several houses prior to the outbreak of the disease on 11th February. The above four villages, separated from each other by a distance of about half a mile, are included in the Bandra Municipality. In Santa Cruz, two miles distant from Bandra, dead rats were found on 12th February, and on 15th February the two first cases occurred in the house in which the dead rats were found. In Joo, which is separated from Danda by a creek, dead rats were found in a house about the 10th of April. The people thereupon removed to a shed for 10 days, and then returned to the house, which had not been disinfected, and three days after their return the first occurred in this house. It would appear that the Bandra rats spread the disease in the adjacent villages, as they entirely disappeared from the town, and were only, in the beginning of June, re-appearing. Dead rats were in the same way discovered at an early stage of the local outbreak in the villages of Vela Parla, Andheri, Goregaon, and Padali, which form an almost continuous line of houses along the Bandra-Ghodbandar Road, the intervals between the various villages being at that time filled up by the sheds of Bombay refugees. The disease appears to have been carried along this line of road as it was carried in Bombay itself. In old Kurla village, which is only separated from new Kurla town by less than half a mile of open fields, no case had occurred, though the disease was very prevalent in New Kurla during January, February, and March. On the 4th of April rats died in the house nearest New Kurla, and although that and some of the adjoining houses were vacated and disinfected, the first cases occurred in the village on 8th April. Here the presumption is that rats came from New Kurla and carried the disease with them.

23,211. How far do you think rats would have to travel from an infected place before a new place became infected?—Under a mile.

23,212. How do you know there was no human intercourse between these two places which infected each other by persons or articles, other than rats, capable of conveying the plague?—The coincidence is rather remarkable in the case of these particular villages. With regard to others at a greater distance from one another, we found we could trace the personal intercourse, but in these villages we were unable to do so.

23,213. It was more likely to occur if they were closer to each other than if they were distant?—Certainly that is an objection. That is possible.

23,214. At any rate, you have a distinct opinion that rats may infect a place?—Yes, I had an instance in Dharwar.

24,215. Will you give us that?—In Hunsikatti, a village in the Nargund Petta of the Dharwar district, two dead rats were found in a house on the 20th of January, and on the 22nd of January one sick rat was seen by me. This village is within one mile of a village called Jegapur, where cases of plague existed at the time.

23,216. Rats became affected, but how about human beings?—I was unable to trace any connexion between the two villages.

23,217. You mean the rats had become infected from this village?—Yes, rats had died in Jegapur.

23,218. I do not think that anyone doubts that rats become infected with plague. There is no question about that. That is all your case shows. In regard to the etiology of the plague, referring to human beings, how do you say that rats bear on that in the communication to human beings? I do not wish you to show whether they themselves become infected or not, but how they become factors in the communication of plague to human beings. Were the infected rats the productive cause of the plague in this new village?—Rats became factors in the communication of plague to human beings by their excreta.

23,219. Have you any instances in which an outbreak of plague appeared to be clearly produced by a previous infection of rats?—In this instance I can only say that the rats died on these dates in the village, and no case of plague had occurred. No person was then affected.

23,220. After the death of rats were they affected?—Then I moved the people out of the village, and after they went out, three cases occurred in the huts.

23,221. How long after?—The people began evacuating the village on the 22nd of January and were all out on the 24th January. On the 13th of February one case of plague occurred among the people in the fields, and on the 17th February two more cases occurred, one being a member of the family first affected. On inspecting the houses of these two people in the village, I found that the seals had been tampered with, and the doors opened.

23,222. How does that prove infection of human beings by rats? That is the point?—From that I concluded that the rats infected the village site, but that the people had gone out before any of them were infected. When these two people came back and entered their houses in the infected site they got the disease, which shows that the plague was there although not amongst the people.

23,223. Assuming they had friends in a village where there was plague, and that there had been intercommunication—personal communication—between them, that itself, without rats, would have been quite sufficient, and that might have occurred, might it not?—I formed my opinion because of the rats dying originally.

23,224. It might have had nothing nothing to do with rats, because another plague patient in another village might easily have been visited, for example, by some of these people, and direct communication without rats might have occurred?—Yes, that is so.

23,225. I want cases which exclude as far as possible obvious fallacies, and show distinctly that rats were the communicating media?—I have no further evidence than that.

23,226. Did you notice any particular distribution of the affected villages in your district in regard to plague infection?—They occurred in circles as it were, round, or in the neighbourhood of, some larger villages in the first instance; they occurred in groups.

23,227. Had this occurrence in any part of your district any association with rivers?—It seemed to follow a course along the bank of the river.

23,228. The majority of the affected villages?—Yes, but it did not cross over from one side of the river to the other very readily. The river seemed to protect the villages on the opposite bank, but the disease seemed to spread along the bank of the river on the side that was infected.

23,229. Did you find many villages distant from the river affected, or were the great majority on the banks of the river?—I would not say the great majority, but about two-thirds.

23,230. Have you formed any idea as to why that should be?—No, I cannot say that I have.

23,231. Can you recollect any conditions in the manner of living on the river bank, as contrasted with the manner of living in the villages remoter from the river, or in the habitations, or in the water supply? The water supply is the same? — The people do not use the river water for drinking purposes.

23,232. What do they use it for?—For washing their clothes and their bodies. The higher class natives go to the river and bathe before taking their food.

23,233. It is not a sacred river?—No.

23,234. In washing do not the natives take the water in their mouths during the process of cleaning their teeth, and sometimes unintentionally swallow a portion of it?—Certainly they do.

23,235. Therefore they would be drinking it to that extent?—Yes.

23,236. You cannot remember any other distinguishing feature?—No, the banks are high, and there is not much difference in the sub-soil water.

23,237. Was the character of the houses worse or better?—I did not see any difference in the state of the houses.

23,238. Not with regard to overcrowding or lighting? —There was no distinction, but, as a rule, along the bank of the river villages are closer together.

23,239. That is to say, if one house happens to become infected, the possibilities of infection of others are greater?—Yes.

23,240. That would go a good way in explaining it? —Yes, certainly.

23,241. I think you have many cases in which partial evacuation has, in the first place, been carried out, and found to be unsuccessful, and then, afterwards, complete evacuation was put into effect?—Yes, I make the following remarks regarding evacuation:— Plague having appeared in Nasik Town in October, I advised the evacuation of the town, population 25,000; 10,000 people were moved out in two or three days, and the rest of the town gradually evacuated as cases occurred. The town escaped with a mortality of between 400 or 500, though plague undoubtedly existed some time before it was discovered, and evacuation was only carried out as areas became affected. In December 1897, while working at Malegaon in the Nasik district, I tried the evacuation of large areas as cases occurred in them, keeping the people out in a segregation camp for 10 days while their houses were disinfected and limewashed, and then allowing them to return while their places in the segregation camp were taken by persons from another newly infected area. It was hoped that even should the disease spread through the whole town—population 20,000—that it would not be necessary to keep more than 2,000 or 3,000 out at a time. This failed, because the people of the supposed unaffected portion began to move their sick about and conceal cases, and the whole town had to be evacuated, after which the disease quickly ceased. During January 1898, I was employed on plague work in the Native State of Palanpur where up to then partial evacuation, as cases occurred, was being carried on. I advised certain measures, namely, the taking of an immediate census of the people, and the evacuation of the whole village on the occurrence of the first indigenous case. Although, owing to concealment of cases, we seldom heard of the first actual case, still the villages were in most cases totally evacuated before the disease obtained any stronghold, and in a few months the Palanpur Political Agency was entirely free from the disease. I afterwards visited Cutch and Kathiawar to advise on plague measures. In Kathiawar, prior to my visit, there was no plague; but while I was there a large village named Kutiana became affected, a nominal roll of the people was at once taken, and they were moved out into camp and mustered daily. Several other towns and villages of Kathiawar have since been affected, but the disease has been kept in check, and I understand that Kathiawar has got rid of the disease altogether.

Major A. V. Anderson, I.M.S.

2 March 1899.

23,242. In these examples, what result followed the after adoption of complete evacuation?—It had the result of getting rid of the disease.

23,243. You have also some instances in which partial evacuation alone was successful?—In 1897, indigenous cases occurred in Wadhwan, a large town of Kathiawar, partial evacuation of the affected locality was carried out and the disease stopped. This result has also been seen in Ahmedabad and in Kutiana in 1897. At that time there was no indigenous plague in the districts concerned. It appears that an isolated outbreak at a great distance from any badly infected district is more easily dealt with than an outbreak in a town or village of an already affected district, although plague measures may be as quickly undertaken in one case as in the other. It would appear that the disease requires time to become acclimatised, as it were, in any new district, and the measures which succeed in such a case will not be equally successful should the disease again appear in that town or village when the adjoining districts have become affected. In the same way the further we go, even within the same district from a bad centre of infection, the more amenable to measures of suppression does the disease become. Might I add that in the Dharwar district, I came across an instance of that in the case of a village called Alur, which was affected in July 1898, at which time plague was only beginning to get a firm hold of the Dharwar district. Twelve cases occurred in this village. The people of the affected locality were moved out, and no more cases occurred. This village has become affected again in February this year, and four cases only have occurred, but in different parts all over the village; complete evacuation has been carried out.

23,244. What has been the result?—We have not had a case for ten days. It occurred in February, but we cannot yet tell what the result will be; they have been ten days free. This village is in Mr. Lushington's charge who can probably give more definite information.

23,245. You have said more than once that you think the disease is a very local one?—Intensely local.

23,246. What is the definite locality to which, as it were, the bacillus seems to confine itself? — The inhabited area.

23,247. What part of it?—The dwelling-house.

23,248. What part of the house?—I should say the floor almost entirely.

23,249. Is there any particular characteristic in the floors of these houses from which this opinion of yours has been drawn?—They are all cow-dunged.

23,250. You have, therefore, no experience of stone floors, have you?—Not in the Dharwar district.

23,251. In any other district?—I have no experience, practically, of stone floors.

23,252. You speak only from your knowledge of mud and cow-dung floors?—Yes.

23,253. I understand you to say that if a case is imported into any district or town, however populous, if you get early information, and can absolutely segregate that patient and all contacts, the disease ought not to spread?—The disease ought not to spread.

23,254. But on the other hand, if it has already spread even to a small extent, if that extent includes distant parts of the town, such treatment is probably ineffective?—Yes, ineffective.

Major A. V. Anderson, I.M.S.

2 March 1899.

23,255. (*Mr. Hewett.*) How many villages are infected in the Dharwar district altogether now?—I cannot tell that.

23,256. Have you formed any opinion as to how the villages in the Dharwar district became infected?—From the towns of Dharwar and Hubli.

23,257. Do you mean that the result of the inhabitants of the towns of Dharwar and Hubli being infected, has been that the infection has been scattered all over the district?—Certainly.

23,258. A number of the people from each of those towns left the town carrying infection with them?—Yes.

23,259. And the district of Dharwar has been extremely badly infected, has it not?—Yes, very badly infected.

23,260. Have you known any other instance in which a district has been so badly infected?—There is no other instance that I know of.

23,261. You have under your charge, at present, 70 villages, have you not?—53 is the correct number, 70 includes the Native State villages.

23,262. Have you any other European officer working in these villages under you?—I had a European officer assisting me last month to whom I handed over charge.

23,263. Practically, there is one officer dealing with all this tract?—Yes.

23,264. What is the area of it?—Thirty miles by ten.

23,265. And some of these villages, I suppose, are a great distance from each other?—Yes.

23,266. Do you think that one officer can manage so many villages satisfactorily?—No, not satisfactorily.

23,267. How many badly infected villages do you think that one European officer can satisfactorily manage, provided that he is personally responsible for seeing that the people remain away from the village sites?—It depends on the distance these villages are from one another.

23,268. Exactly, but how many villages in the immediate neighbourhood of one another, can one officer properly supervise in that respect?—Not more than two large villages of over 2,000 population.

23,269. Would you be disposed to place reliance on the efficacy of Native agency in preventing villagers from coming back to an infected site?—To a limited extent.

23,270. Would you require them to be supervised by British officers?—Certainly, always.

23,271. You say in your précis of evidence that no villages had become infected after re-occupation before January the 6th. Have any of them become infected since that date?—Only one.

23,272. Do you consider that the evacuation of villages during the rains, in the Dharwar district, was accompanied by great hardship to the people?—Certainly, there is hardship during the rains in a black cotton soil.

23,273. Do you think that the evacuation and the exposure to which people are subjected during the rains, render them more liable to sickness generally?—During the rains it does.

23,274. And that if you evacuate the people during the rains, in order to escape plague, you make them more liable to other diseases?—Yes.

23,275. Do you think that the people when influenced by the exposure to which they are subjected when out of the village during the rains, are more liable to take the plague?—I do not think so.

23,276. Do you think that when people are turned out of their villages during the rains, and subjected to this exposure, that there is a strong temptation for them to go back at night and sleep in the infected site?—Certainly.

23,277. And that consequently your measures may be to a great extent defeated owing to their doing this?—They require closer supervision.

23,278. If then you had a district infected as Dharwar was during the past rains, you would require an enormous staff of European officers working in the district?—Certainly, at the end of the rains.

23,279. Do you not think that in the Dharwar district there were many cases in which villages were infected during the rains, and the infection was not discovered until a long time afterwards?—Certainly, I am quite sure of that.

23,280. So that probably you would have required during the rains a very large staff?—Yes.

23,281. Then you speak of the fact that cattle are kept in the same house as the people, do you partially mean that the cow-dung falls upon the floor and thus affords the bacillus a soil which is favourable for its growth?—I think so.

23,282. I understand you to believe in the theory of the efficacy of disinfection, if it is properly carried out?—Yes, if it is properly carried out.

23,283. And that you would be quite satisfied with a disinfectant which effectively disinfected the floor?—No, chiefly.

23,284. I understood you to think that the infection exists almost entirely in the floor?—Almost entirely in the floor.

23,285. Where else do you think the infection exists?—It may exist in the walls; it may exist in any bundle of rags which may be overlooked, not actually in the room, but in some covered place within the wall, such as a hole in the wall which cannot be reached by any disinfectant we use.

23,286. Is it your opinion that the walls as such, and the roof as such, are likely often to contain infection?—They are not likely to do so.

23,287. Even if disinfection of the villages is carried out, and it is not always thoroughly done, it does a certain amount of good, does it not?—Yes, a certain amount of good.

23,288. Do you think that one of the causes of the infection of villages situated on a river bank may be that outsiders come more to those villages?—No, I do not think they do, because they do not use the water for drinking purposes.

23,289. Have you noticed in your experience that an outbreak of plague results in the general mortality (apart from plague) falling below the normal?—I think that is due to a defect of registration. When village officers once report plague they are very apt to put down every death that occurs as plague. If death occurs within a week of a man falling sick it is put down as a plague case. All cases of fever which terminate fatally are put down as plague cases after plague has been declared.

23,290. Then you find that if plague has been declared the village authorities who are responsible for notification notify all the cases of plague, and some notify as cases of plague sickness which is not plague at all?—In most instances; of course there are certain exceptions

23,291. Where there is concealment?—Yes.

23,292. Under ordinary circumstances would it not be rather difficult for the village officer to be certain that the original case which occurred in his village was a case of plague?—Yes.

23,293. With the best of intentions he might be deceived?—Yes.

23,294. Village Headmen are fairly reliable, as a rule, in reporting cases of cholera, are they not?—They are.

23,295. Do you attribute that to the fact that they have no difficulty in recognising the disease, owing to their familiarity with it?—I do.

23,296. Do you think that they can be expected to do the same thing as regards plague at present?—No, I do not think so.

23,297. Do you think that there is any organisation which you could substitute for them over the country generally which would help you to get immediate notification of cases of plague in rural areas?—Yes, certainly.

23,298. How would you do that?—By preparing a special form of report to be filled in by inspecting officers, who will fill in the facts, and not their own opinions as to what any particular disease may be, that is the mere fact that there are so many sick persons in

the village, and so on. The following is the form of Report.

Inspection Report Form of Circle Inspector.

Population.	Mortality during the last six months.	Cause of death, during the last four weeks.	Age and caste of death during the last four weeks.	Were any of these related to each other.	Did any two or more die in the same house.	Houses in which deaths occurred inspected.	Grave-yards and burning grounds inspected.
1.	2.	3.	4.	5.	6.	7.	8.

23,299. What class of men would you put on as inspecting officers?—Men of the class of Circle Inspectors, or vaccinators.

23,300. Who are the Circle Inspectors?—I understand that Circle Inspectors are subordinates of the Land Records and Agricultural Department.

23,301. And the vaccinators are subordinates of the Sanitary Department?—Yes.

23,302. You are a Deputy Sanitary Commissioner?—I am.

23,303. Do you think that the efforts to get early and proper notification of disease might be improved if you could import into the Sanitary Department some Assistant Surgeons to supervise the work of vaccinating?—Certainly.

23,304. Do you think that it would be a good thing to have a certain number of Hospital Assistants employed as vaccinators?—Certainly.

23,305. Do you think that these measures would help you to get early notification?—They would.

23,306. Do you know anything about the byelaws in Municipalities requiring a householder to report the occurrence of death? Is it the case generally that in Municipalities in the Bombay Presidency there is such a byelaw?—They are supposed to collect and keep a return of all deaths occurring within a Municipality. This is generally done by a special clerk, who usually collects his information from the village Mahars.

23,307. Is there no obligation placed by the law, or by a byelaw, upon the householder to report a case of death himself?—In most Municipalities there is such an obligation.

23,308. Is that byelaw usually carried out?—I do not think so.

23,309. What is the reason that it is not carried out?—It is so seldom enforced.

23,310. By the Municipality?—Yes.

23,311. It is your opinion that it is allowed to fall into practical disuse?—That is my opinion.

23,312. What was the form of seal with which you used to seal up a house?—A slip of paper with the Municipal seal stamped on it, and dated. Nargund being a Municipal town, we had a Municipal seal. Elsewhere we have simply a piece of paper with the name of the house and the date, signed by one of the subordinate officers. I had five native subordinates. These seals were applied to the doors, but as there were so many villages affected at the time I first began working, I had to rely on the village officers putting the seals on and dating them, and I had to rely on my subordinate seeing that this was done.

23,313. When you say putting them on, how were they fixed on?—With gum.

23,314. Would not some other method be required in the rains?—Certainly, in the rains.

23,315. Do you find that the people remove them?—They do.

23,316. Can they remove them and put them back again?—In some instances I believe they have done that, but it has only recently been detected.

23,317. In referring to your operations at Igatpuri, you said that after you had resorted to the proper solution of perchloride of mercury, you could not say that better results accrued. Can you tell us a little more definitely what actually did happen there?—I have no record of the exact date on which I discovered the mistake that was being made in Igatpuri of using a solution of perchloride of mercury 10 times too weak, but it was some time towards the end of August when the flying column had been working about a month. I append a statement of the daily returns from Igatpuri, which show that no improvement took place during September.

Major A. V. Anderson, I.M.S.

2 March 1899.

For Igatpuri Town for 1897.

* From this date all local cases occurred.

23,318. You thought at the beginning of the epidemic that the disease was a coast disease?—Yes.

23,319. Have you anything further to say upon that now?—I think it was a coast disease, because it had great difficulty in securing a hold in any new town or village. We know that many cases escaped from

Major A. V. Anderson, I.M.S.

2 March 1899.

Bombay at the beginning of the epidemic, and even after railway inspection was put on still a large number of cases got through. For example, in Nasik before indigenous plague occurred there we had 35 imported cases. Those 35 imported cases, I think, did no harm.

23,320. Do you think that bubonic cases are usually likely to cause spread of the disease?—I think so.

23,321. For what reason?—Because the germ, I understand, is in the excreta.

23,322. You think, then, that the infection is carried in the clothes of the bubonic patient?—Yes; in all probability it is in the men's clothes.

23,323. When you speak of plague as a coast disease, would that mean that you think it is a disease which requires some time before it can assimilate itself to an inland place?—Yes, certainly. One other point which struck me concerning the outbreak in the Thana district was that no indigenous case occurred in any town or village more than five miles from tidal water. The disease, when it first appeared in Bombay, was undoubtedly a coast disease, and required a high sub-soil water for its development; a town with a good water supply and no drainage suffering more than an equally dirty town with a deficient water supply.

23,324. Have you found in your subsequent experience that this theory still holds good, that the towns with a good water supply are attacked, and those with a bad water supply are not attacked?—Not so much now.

23,325. Do you think, now the disease has spread about in the interior a good deal, that it more easily attacks a fresh place than it would at the beginning?—Within a certain area. Places in the Deccan are much more easily infected now. Nasik, I understand, this year has been infected from one single imported case, whereas the previous year it took at least 40 imported cases to infect the town.

23,326. Might not that depend to a certain extent upon the character of the imported case?—That is what I mean.

23,327. Supposing you had a pneumonic case, would it not be more likely to infect the locality?—I do not mean that.

23,328. But might it not be so?—No; I think it is more dependent upon the locality where the man comes from—the locality from where the man comes with relation to the place he goes to. If they both belong to the same district there is greater danger from a single case than if that case had gone to an entirely different district, as, we will say, from the Nasik district to the Central Provinces; that case would not have been so liable to infect a town there as to infect a town in the man's own district.

23,329. And in the same way a case from Bombay would not be so likely to infect Nasik as a case from some other place in the Nasik district?—That is my opinion.

23,330. The town of Sholapur has a population of 60,000 inhabitants, has it not?—Yes.

23,331. When you speak of the complete evacuation of the town of Sholapur, what do you exactly mean?—I would rather not give evidence upon Sholapur, because my experience was limited.

23,332. I should like to have an answer to the question, because you have expressed an opinion in favour of evacuation upon a large scale; did you mean that the whole 60,000 people were kept under the eye of the authorities?—Not the whole 60,000. Many went away. At least 20,000 left the district altogether, and we did not know where they went.

23,333. But did they not go about the country carrying plague with them?—Undoubtedly they did.

23,334. Then the outbreak at Sholapur was put under, to a great extent, at the expense of other places?—Yes, because the evacuation was not carried out at once. By "at once" I mean as the different areas of the town become infected. Sholapur was infected by degrees; one area was infected, and then another, and another. It had spread over several areas before any attempt whatever was made to evacuate the town.

23,335. To effectively evacuate a town of 60,000 persons (or whatever the population may be) so as to prevent the spread of plague it would be necessary to see that the people did not get away first, would it not?—Certainly.

23,336. Do you think you will ever be able to do that in a big town?—Not altogether, but my contention is that if a part of a town with a population of, perhaps, 2,000 people becomes infected, if we clear those 2,000 people out before they are badly infected they will do very little harm, even if they go away anywhere.

23,337. Then you think that the people went out from Sholapur after they were badly infected?—Yes.

23,338. And they certainly did a great deal of harm?—Yes.

23,339. What is the population of Ahmednagar?—Forty thousand.

23,340. The plague was never bad there, was it?—No.

23,341. Were the whole of those 40,000 people moved out of the town of Ahmednagar?—I cannot say from my own personal knowledge, but I understand the whole town was vacated.

23,342. The whole town was vacated, and I presume the same result as regards the going out of the people happened as at Sholapur?—No.

23,343. The same proportion of people did not fly away?—The same proportion of people did not fly away; and the disease was not spread by Ahmednagar.

23,344. I want to know whether, in your opinion, the same number of people did go away?—I do not think so.

23,345. The tendency to run away would be greater as the disease was worse?—Yes.

23,346. Have you formed any opinion as to the necessity for close segregation in the case of people who are evacuated from the town as contacts?—I consider that contacts ought to be kept in camp by themselves, if possible.

23,347. Do you think that when you have evacuated a town you should keep all the contacts in close segregation, that is to say, prevent them from going about their ordinary business, and keep them in a camp the whole 24 hours of each day?—Yes, I think it should be done, if possible.

23,348. You would not allow them to go out of the camp during the day, and simply require them to sleep in the camp during the night?—It would be preferable certainly to keep them by themselves. I do not think the risk of allowing them to go out would be very great, but it would be more efficacious to keep them under close supervision during the entire day.

23,349. Is it your experience that, when you have people who have been subjected to infection in a camp, there is a danger of the disease spreading amongst a certain number of the inmates of the camp by contact?—Individual cases do occur. It is rather exceptional, but they do occur.

23,350. As a general rule the health of the people who come into a contact camp is good, is it not?—Yes.

23,351. (*Mr. Cumine.*) Do you not think that a sketch of the village site with the deaths marked with crosses against the houses in which they occurred would be even of more value in telling whether plague was there or not, than the mere numbers of deaths occurring in the village?—Yes, certainly.

23,352. As regards the tidal rivers in the Konkan, they are great highways, are they not?—Yes.

23,353. While railways and roads are watched (sometimes at any rate) are the tidal rivers watched in the same way?—An attempt was made, at any rate in the Thana district, to watch the native craft.

23,354. When a village is evacuated in the rains, do the people, in order to protect themselves against the weather, make their huts almost as airtight as the houses in the village site?—They do.

23,355. Are those the conditions which favour the infection of the floors, and the consequent spread of plague to other members of the family where one person is attacked?—Yes.

23,356. Have you experience of the treatment of patients in their own houses in an unevacuated town or village, the leaving patients in their houses, putting them upon beds, and disinfecting the floors daily?—No. I have experience of their being left in their houses in Bhiwandi. That was done during the last

outbreak. The people were not compulsorily moved to hospital.

23,357. Were they put upon beds?—I think not.

23,358. Were the floors disinfected daily?—No.

23,359. What was the result of the leaving the patients in their own houses?—There was a very severe outbreak of plague. Originally the population of Bhiwandi was about 15,000, but it was certainly reduced to considerably under 10,000 by the flight of the people. There were 2,000 cases.

23,360. (*The President.*) You expressed the opinion that people who are removed in the rainy season to huts are affected by general disease to a larger extent than if they had not been removed?—That is my opinion.

23,361. Have you any experience that it ever happened?—No, I have had no experience.

23,562. You have, however, carried out evacuation during the rainy season?—Yes.

23,363. You made a remark about the effect of the water supply in two places. In one place there was a good water supply, but in the other place there was a deficient supply. I understood you to say that where there was a good water supply there was much plague, and where there was a deficient water supply there was less plague. Do you attribute the difference to the water supply?—I attribute it to the moisture of the soil, because in that town there is defective drainage.

(Witness withdrew.)

Lieutenant G. Thomas, I.S.C., called and examined.

Lieut. G. Thomas, I.S.C.

23,364. (*The President.*) I believe you are in the Indian Staff Corps?—Yes.

23,365. Where has your experience of plague chiefly been acquired?—I have been on plague duty in Dharwar district since the 27th of June. I was through the epidemic in Hubli as Chief Sanitary Plague Superintendent. After that I went into the Hubli taluka for about three weeks. Since then I have been in Ron taluka, engaged in district work in the villages. The subject upon which I wish to give evidence is the disinfection of houses in Hubli when I was Chief Sanitary Plague Superintendent.

23,366. Do you hold a special appointment now?—I am the Special Plague Authority in the Ron taluka. As I say, I wish to give evidence on the disinfection of the houses in Hubli. I insisted upon a payment for the disinfection, and the results were exceedingly good. When the disinfection was gratuitous I found that a good many people were giving bribes to the disinfecting muccadums in order to write "Disinfected" over the door, and go away. I found that this was not having good results, so about the middle of August I instituted a fee for disinfection. The people had to pay Rs. 2 for disinfection,—for a certain number of perchloride of mercury powders. In addition to that, they were advised to take more powders, according to the size of the house. Since I started that I have had most excellent results. The notes I have prepared show that there was an immunity of 94·6 per cent. after the first disinfection.

23,367. (*Mr. Cumine.*) Did the people do the disinfection themselves?—No, my parties did it, but the people had to pay for it. Having to pay for it they took a very lively interest in disinfecting the houses.

23,368. Why? I suppose the reason they objected to disinfection before was that it injured their things, or that they had to remove their property,—was not that it?—It was not, to a certain extent. It is the way with these people. If they have to pay for a thing they think there is something in it. I am sure it had a very marked result; the disinfection was much more satisfactorily carried out.

23,369. What were your grounds for thinking that the disinfection was more satisfactorily carried out?—Because we did not have to disinfect the same house so frequently.

23,370. In what month did you start your system?—In August. I have only the office copy of my lists here. I have sent in lists of some 450 houses taken in the worst galis in the town.

23,371. When did you allow the inhabitants to return to the disinfected houses?—The same day.

23,372. What privilege did you offer a man in return for his paying for the disinfection of his house?—Absolutely none.

23,373. Did you not offer him the privilege of allowing him to return to his house immediately without staying in the segregation camp?—No. Everybody had to pay Rs. 2. The Municipality was bankrupt. They could not afford to go on with disinfection thoroughly, and I suggested that the people should pay the money.

23,374. If you did not allow them to return to their houses, instead of going to the segregation camp, how do you know that the disinfection was so efficient?—From my records.

23,375. But the people were not in the houses; they were out in the segregation camp?—If they were twice-inoculated they were allowed to go back to their houses that evening.

23,376. Would you not expect such people to be protected in any case?—They are in a great many cases.

23,377. (*The President.*) These were only the plague houses?—Yes.

23,378. How many houses were there in this town?—About 10,000.

23,379. From how many do you draw your deductions?—Four hundred and fifty houses.

23,380. (*Mr. Cumine.*) You allowed, you say, the twice-inoculated to return to their houses after they had paid for the disinfection of them?—Everybody was allowed to return to his house if he was twice inoculated, whether his house was disinfected gratuitously or not.

23,381. If a man was not twice inoculated, was he allowed to return to his house if he paid for his disinfection?—Not if we could find him.

23,382. What did you do with him?—We sent him off to the segregation camp until he was twice inoculated.

23,383. If he was not allowed to go into his house but kept in the segregation camp, how did you know his house was efficiently disinfected?—That is what I have deduced from my returns. I have a house here, No. 1,909. There were 13 people in that house, and nine died before it was disinfected. When the tenth died the house was disinfected, and no more cases occurred in it.

23,384. Where were the people?—The people were in the house while these nine people died. We subsequently discovered that they had buried them surreptitiously.

23,385. After the house was disinfected upon payment where were the people sent?—We sent them off to the segregation camp; they came back, and they are alive still.

23,386. It is from the fact that they were unaffected after their return from the segregation camp that you deduce the efficacy of the method?—Yes.

23,387. (*The President.*) Did you do anything else; did you open up the house?—I burnt the floors.

23,388. Did you open up the house and take away the roof?—Yes, we opened up the roof.

23,389. If the people were in the segregation camp, how could they attend to the disinfecting of their houses?—If no member of the family was inoculated we allowed one to come down to superintend the disinfection of the house. He was then sent back to the segregation camp.

23,390. Were the houses also thoroughly cleaned?—Yes.

Lieut. G. Thomas, I.S.C.

2 March 1899.

23,391. And thoroughly ventilated?—It was difficult to ventilate those houses which had mud roofs.

23,392. What did you do with them?—Knocked holes in the walls. We did not get so much sunshine on the floor as we would have done had the houses been tile roofed.

23,393. Air was admitted freely?—Yes.

23,394. (*Mr. Cumine.*) Did you apply perchloride of mercury to each floor on one day only, or on a succession of days?—Only on the day on which the house was disinfected.

23,395. Then the difference between the system in force before you instituted your cash-payment system, and the system afterwards, is that the people personally took an interest in the disinfection after they had paid for it and they did not before?—Yes; and they did not allow the disinfecting parties to shirk their work in any way.

23,396. Has your system convinced the people of the efficacy of disinfection?—Absolutely.

23,397. How do you satisfy yourself that the house owner who used to pay the disinfecting gang a rupee or so before for omitting to disinfect his house does not do so still?—He may give the disinfecting muccadums money, but he certainly has his house disinfected too.

23,398. How do you know that?—I inspect it personally. I had four European Inspectors of the Poona police, who gave me the very greatest assistance in my disinfection.

23,399. Had you not them in the former days when the people used to pay for escaping disinfection?—I had not European Inspectors until within a week of my introducing the system. I used to go round from one house to another. I could not visit 80 houses in one day. I went round as many as I posiibly could. I prosecuted one mucaddum for taking Rs. 4, and he got a month's imprisonment.

23,400. Have you any figures to show the efficacy of this system of disinfection of yours? I believe you have notes with reference to some of the worst galis, have you not?—I have taken seven or eight of the worst galis at Hubli, and from the date that I started this disinfection, I have kept a record, and have made a list of all the houses which are disinfected. This list I have made out according to galis, and have been able to see any houses which have been disinfected more than once, owing to deaths having occurred in the house. The result leads me to the conclusion that there is great benefit derived from disinfection, seeing that so few galis show houses which have been disinfected more than once. I might say that my system of disinfection is the kiln process, as well as a perchloride process.

23,401. What is the kiln process?—Burning the floors.

23,402. Did you dig them up?—No.

23,403. Did you lay grass or wood on them?—Cotton stalk wood.

23,404. (*The President.*) Do you also open up the house?—If necessary. If the house is a dark house, we knock a hole in the wall and order them to put in a window. To get a 3-feet window we have to make a 5-feet hole, because they plaster it up so as not to have a big window. In this list I specially mention the case of Yellapur gali.

23,405. (*Mr. Cumine.*) How many houses did you disinfect in that gali?—I have 39 on this list, and out of those only one had to be disinfected twice, after a period of 11 days. I was able to spend a day in Hubli on my way here, and I inquired in regard to this house, and they told me that the woman who died was 75 years old, and that she had been sick with a cough for some time, and that there had been no bubo when she died. They told me that she died of grief.

23,406. Was the reason of your disinfecting each of these houses the first time, that a plague case had occurred in it?—A plague death.

23,407. Did you disinfect immediately after the plague death?—As a rule it was the next day.

23,408. Will you tell us about another gali?—Here is Hirripet. There are 23 houses only, and not a single house had to be disinfected again. Then there is Kamaripet, in which there were 38 houses, and only one had been disinfected again.

23,409. Will you give us the whole list?—Yes, the list is as follows:—

	Houses once disinfected.	Houses twice disinfected.
Ganeshpet	37	3
Yellapur	39	1
Siddanapet	24	1
Mangalwarpet	14	1
Ghantikeri	12	1
Bhoosapet	21	0
Bawapur	45	2
Kawalpet	37	2
Dajibarpet	21	0
Kamaripet	38	1
Sidwarpet	27	3
Pinjarooni	18	1
Arklekatti	18	1
Mullabada	17	1
Hirripet	23	0
Ninganapet	12	0
Badigeroni	6	0
Simpigali	5	0
Delaioni	12	1
Dhoragali	3	0
Pudharigali	6	0
Hirepet	9	0

23,410. Has this convinced you of the efficacy of perchloride of mercury as a disinfectant?—Yes, and burning; perchloride of mercury certainly for the clothes. That is what I lay great stress upon; they must disinfect the clothes.

23,411. You said, I think, that the success of your treatment had convinced the people of the efficacy of your system of disinfection?—Most certainly.

23,412. In what way have they shown that they are convinced?—As soon as I can get the whole figures compiled, I could show you a number of houses which have been disinfected of the people's own free will, independently of having had a case brought to our notice.

23,413. Do people come forward and ask you to disinfect their houses?—At one time they did when plague was very bad. I cannot say why, but they did.

23,414. Do you give any special privilege to people who pay for the disinfection of their houses over those who do not pay for it?—Yes.

23,415. What is that?—Instead of taking the whole of the tiles off their roofs, they only have strips taken off.

23,416. Do you think that that may be the reason of the people paying for the disinfection, and not a belief in the efficacy of the disinfection?—No; I only did that because the supervisors were making money out of the people, consequently I had to be severe. The supervisors went to a man, and said, "If you will give me a rupee, I will give you a gratuitous pass for disinfection." To guard against this I had to be rather severe. If the people were too poor to pay, I housed them in a camp for the time their roofs were entirely removed.

23,417. In the case of the houses of which you have given us particulars in your table, the twice-inoculated people were, you say, allowed to return to their houses immediately after disinfection?—Yes, provided they were twice inoculated. If we found anybody who was not twice inoculated, we segregated him.

23,418. When was he allowed to return?—As soon as he was twice inoculated. We did not recognise once inoculation.

23,419. Was an uninoculated person allowed to return to his house after 10 day's segregation?—He was kept 21 days in segregation.

23,420. And after that?—He was allowed to come back to his house. There were cases, of course, in which once-inoculated people were never segregated. I know a case in which a house had to be disinfected for a death, and never had to be re-disinfected, and the people were only once inoculated.

23,421. You have experience in the villages now?—Yes.

23,422. Do you use perchloride of mercury as a disinfectant in the villages?—I have not done any disinfecting there. I am going to begin now.

23,423. You do not know whether the people in the villages have been converted to a belief in the efficacy of disinfecting houses with perchloride of mercury?—I cannot speak from personal experience, but I know what has happened.

23,424. What has happened?—That people have been very glad to do it, and have come and asked for it. The people in the villages which it had not been intended to disinfect have come and asked for it to be done. They are very anxious to have it.

23,425. Has any special privilege with regard to liberty to return to their houses been given to people in villages who pay for the disinfection of their houses?—As yet there is no privilege, but it is understood when a village is disinfected that, provided no more plague occurs, the people will be allowed to return to their houses.

23,426. Do you think it is that privilege which makes the people anxious to get their houses disinfected?—No.

23,427. (*The President.*) How do you know?—When they come up they know they will not be allowed to go into their houses for some time.

23,428. But they are allowed to go in if the houses are disinfected?—I was not intending to disinfect Ron; I was going to allow the people in without disinfection, but the people had asked me to disinfect the town. It is in consequence of that that I am now going back to disinfect this town of 6,000 inhabitants.

23,429. In these houses in the galis the patients and contacts were removed for a short time only; how long were they removed from the houses?—If they were twice inoculated, there were not removed at all, but the inoculated members were sent to segregation camp.

23,430. What kind of houses were in these galis?—A good many of them were very good houses with rooms from 18 to 20 feet. In Yellapur as a rule there are good houses.

23,431. What is a good house?—A good house would have a large room in the middle, about 14 feet high, in which they keep the cattle, then on one side they would have a plinth of, say, four feet in height and eight feet broad off which again there would be two or three rooms. That would be a good quarter.

23,432. And the other galis?—Ganeshpet is a small gali; they are mostly labourers working in railway workshops. They have bad houses, very small and covered with tiles. The third bad gali was Kamaripet. These people were all potters, and they have bad houses as a rule.

23,433. Consisting of several chambers or one chamber?—About three rooms.

23,434. You speak of making holes in the walls and also of removing tiles, did you do both?—We never made holes in the walls to the exclusion of taking the tiles off the roof. The latter was always done.

23,435. And the holes in the walls were only made in those cases where it seemed to be necessary?—Yes, but it was not meant as a temporary measure, but with a view to permanently improving the house.

23,436. Supposing you have removed the tiles from the house, how could a person who was ill remain in it?—Every sick person was sent to the hospital.

23,437. How did those who had been twice inoculated continue to remain in the house when the tiles were off?—In the times of the rains they used to go into somebody else's house, or if they liked to make their own arrangements they could stop in their houses.

23,438. In these houses you therefore reproduced the conditions of a hut in the camp, that is, you increased the amount of ventilation?—Yes.

23,439. That is a disturbing element in all the deductions you draw?—To a greater extent in houses which were gratuitously disinfected.

23,440. Supposing these people had not been inoculated, and had been sent to segregation or health camp, would you anticipate that much plague would occur among them? Have you experience of cases occurring in the segregation camp?—Certainly.

23,441. Does plague occur much among people in the segregation camp?—I have heard of five cases. If the huts are properly constructed and ventilated the plague stops. You get very much the same conditions by opening up the houses.

23,442. Your disinfection consisted in the employment of perchloride of mercury, of burning the floors, and then of whitewashing?—I did not whitewash.

23,443. Did not the people whitewash?—A great many of them did, but it was not compulsory. In Hubli town I did not compel anybody to whitewash, but they generally did it. Whitewashing is to be made compulsory in the villages. My experience of disinfection is based entirely on Hubli.

23,444. Where the disinfection by chemicals was also reinforced by disinfection by free admission of sunlight and fresh air, and burning of the floor?—Yes, we did everything we possibly could.

23,445. You have had some experience of inoculation?—Yes, I have been inoculated myself.

23,446. I mean outside of yourself?—Yes.

23,447. You have seen a good deal of inoculation in the natives of the town?—Yes.

23,448. What opinion have you formed?—That it is an exceedingly good thing. I think it has a good effect on immunity.

23,449. If you only allow into the houses those people who in your opinion are immune against plague, how can you form an opinion as to what you have done in the houses by way of preventing plague?—It has been impossible to keep only those twice inoculated in the houses.

23,450. Or even those once inoculated?—If I had had one quarter to look after myself I could have done it.

23,451. Does nobody go who has not been once inoculated?—Cases have occurred in which uninoculated people have escaped the notice of the plague authorities.

23,452. But the great majority were once or twice inoculated?—Yes.

23,453. And were, in your opinion, to some extent immune already?—Yes.

23,454. (*Mr. Cumine.*) What idea, do you think, is at the bottom of the natives' desire to get their houses disinfected now? Is it merely that they have to pay for it?—There is a spirit of rivalry and competition in the matter which must also be taken into account; they like to think they have paid more for it than other people. One man says, "Oh, you paid Rs. 5 for your "disinfection; look at my chit, I paid Rs. 7.8." Another one says he paid Rs. 14, and he is talked about all over the town. A native does not believe in the value of what he gets for nothing; he thinks more highly of things for which he has to pay.

23,455. (*Mr. Hewett.*) Were you at Hubli when the original census was taken?—I was not; I came down after the epidemic began.

23,456. When did you get to Hubli?—On the 27th of June.

23,457. Were you occupied in taking the census every week?—No.

23,458. Did you get reports from the supervisors?—No. That was the Chief Plague Superintendent's work.

23,459. You know nothing about the figures?—Nothing that I could tell you. I heard them in conversation.

23,460. You were there in the middle of September?—Yes.

23,461. What do you think was the number of uninoculated persons actually resident in the town of Hubli in the middle of September?—I should say about 5,000.

23,462. You do not think it went below 5,000?—No.

23,463. While you were at Hubli the people were not allowed to leave the place, or supposed not to leave the place, except on a pass, were they?—No.

23,464. And that pass was only given to inoculated people?—Only given to twice-inoculated people, ten days after inoculation.

23,465. Whether they went by road or by rail?—Yes.

23,466. But a good many persons went who did not get passes, did they not?—I never found any.

23,467. If they did not, how did it happen that so few uninoculated persons were left in the town?—Because,

Lieut. G. Thomas, I.S.C.

2 March 1899.

I take it, that the majority were inoculated and went away, reducing the population.

23,468. The initial population was 55,000, and it went down to something between 37,000 and 38,000; that is a difference of 18,000 people. If only 5,000 of these were uninoculated, a certain portion of the uninoculated persons must have left Hubli?—Yes.

23,469. And they must have gone without passes, must they not?—That would be very difficult to say.

23,470. Do you think that the people leaving Hubli took the plague into the Dharwar district in the neighbourhood of Hubli?—Yes, I do think so.

23,471. Do you think they were mainly inoculated or uninoculated persons?—I do not think that the twice-inoculated people would have taken the plague with them.

23,472. Dharwar district has been very badly infected, has it not, both in the neighbourhood of the town of Hubli and the neighbourhood of the town of Dharwar?—Yes.

23,473. Plague is now spread all over the district, is it not?—Yes.

23,474. In your taluka how many villages are there which are now infected?—I have two villages which are submitting returns, and I have two others infected, but they have ceased to submit returns.

23,475. Then practically it is at present extinct in your portion of the district?—Yes, I hope so.

23,476. Have you been employed at Dharwar and Hubli during the rains?—Yes. On the 1st of November I went out into the Hubli taluka; and there was rain on the 8th of November for four days.

23,477. How many villages are there in the Hubli takula?—I could not say.

23,478. Could you tell us the maximum number of infected villages you had to deal with in the Hubli taluka?—I had about 20 infected villages myself.

23,479. And were there other officers working in it besides?—Yes, there were others besides in the south of the taluka, which Mr. Westropp, the First Assistant Collector, was looking after.

23,480. Did you find it possible to look after the 20 villages yourself quite satisfactorily?—No, I do not think I did.

23,481. What number of villages do you think you could have looked after satisfactorily so as to prevent the people who are evacuated from perpetually going back to their villages, and so on, in those days when you had difficulties to deal with?—In those days the difficulty I had to deal with was the fact that I had no staff at my disposal.

23,482. Then we will say during the rains?—During the rains I could look after a tract of about 30 square miles.

23,483. Could you look after such a district which was full of infection?—I think so; a tract of about 13 villages, with the staff that I have at my disposal now.

23,484. Thirteen badly-infected villages?—Yes.

23,485. How often do you think you ought to visit a village which is infected?—I ought not to leave it for more than three or four days.

23,486. Has your experience led you to form an opinion as to whether turning the people out during the rains caused great hardship?—Yes, certainly; I think it causes exceedingly great hardship.

23,487. Do you think that the general exposure made them liable to disease?—Yes, I think it did. I can give you one case. There is a village called Umachgi in the Hubli taluka, which had plague on the 30th of September. There were cases being returned every day as plague. Owing to the rains on the black cotton soil they asked Mr. Westropp to allow them to go in. He said, "You may go into your village, but you must "go out as soon as the rain stops." They returned two cases the next day. They have been living in that village ever since, and they have had no more cases of plague up to date. That was in an infected site.

23,488. How do you account for that?—I cannot.

23,489. You did not disinfect the houses?—No, we could not disinfect. That is only a single instance.

23,490. What I mean is this: are the people more subject to disease when they are sent out into the fields during the rains?—They complained bitterly about it. They look most wretched, and in a few cases I gave them blankets. During the rains they were put to more hardship, but now they do not mind it in the least. A great many of them told me that they liked being out.

(Witness withdrew.)

Rao Bahadur R. R. Bhardi.

Rao Bahadur R. R. Bhardi called and examined.

23,491. (*The President.*) I believe you are District Deputy Collector at Dharwar?—Yes.

23,492. (*Mr. Cumine.*) I think your experience of plague has been amongst the villages in the Dharwar district, has it not?—Yes.

23,493. When did you take charge of your duties?—In March.

23,494. In what talukas have you had experience?—In Gadag taluka especially.

23,495. And what others?—I had charge of Navalgund and Ron taluka also for a time.

23,496. In spite of all efforts plague was imported?—Yes.

23,497. Was it brought by human agency, or by what agency?—By human agency; there is no doubt about that.

23,498. There were two distinct centres, I believe, one in the Ron taluka and one in the Gadag taluka?—Yes, but one of them, Aher in the Ron taluka did not actually become a centre of infection as infection was not carried from that village to any other village.

23,499. Where did the infection come from in each case?—It came from Hubli.

23,500. In the second centre I think plague raged for a long time without being discovered?—Yes.

23,501. The result was that a lot of people fled from the second centre?—Yes.

23,502. Did they carry infection to many villages in your district?—Yes.

23,503. They carried infection to some villages, and infection was carried from those villages to other villages?—Yes.

23,504. By the end of November what was the state of things?—By the end of November six villages in the Gadag táluka, five in the Ron táluka, 21 in the Navalgund táluka, five in the Mundargi Petta and one in the Nargund Petta were found to have been infected. Early in December the Navalgund and Ron tálukas and the Nargund Petta were placed in the charge of separate officers. I have been able to ascertain that in many of the villages infection was carried by human agency. I have not come to know as yet that rats carried infection from village to village in my charge, and I doubt whether they can carry it from village to village unless the villages are very close to each other as Jantli and Shirur in the Mundargi Petta. In some of the infected villages, however, rats were reported to have died, but I am inclined to believe that they caught infection which the human agency had brought.

23,505. How many villages in your charge are infected at this moment?—Altogether 39 villages, excluding the town of Gadag particularly, of which I have charge.

23,506. Do you find it possible to attend to so many infected villages? On an average how often can you visit each of the 39 villages?—It is not possible to attend to so many infected villages when I have to do plague duty in addition to criminal and revenue work. I find that I visited about half the number of infected villages. I visited one village more than three times, some three times, some two times, and the others only once. Many of the infected villages which I could not visit were visited by me before they were infected, and they happened to be infected when I was touring away from them in another direction. I have got the Mamlatdar, Mahalkari, the special Head Karkun, the district Abkari Inspector, and other circle officers to work under me.

23,507. According to your opinion, what is the best measure for suppressing the epidemic?—Evacuation.

23,508. Have you any instance where partial evacuation has been successful?—Yes, I have one instance.

23,509. As a rule, is it a failure if plague has "caught on" in a village?—Partial evacuation was successful in one case.

23,510. In most cases, if plague is established in a village, is partial evacuation sufficient to stop it?—No.

23,511. I suppose the chief thing to be desired is to keep the plague out of a village, is it not?—Yes.

23,512. Do you find that people will do this efficiently themselves? Are they alive to the importance of it?—I doubt whether they will do it themselves.

23,513. As regards the early detection of plague, what have you to say?—Early detection of plague is the chief thing to be aimed at. If it is detected before it has taken deep root into the village, even partial evacuation and disinfection of the infected houses are, in my opinion, sufficient to suppress it. But when it is detected after a considerable portion of the village is infected, complete evacuation is the best means of destroying the infection. But complete evacuation can be effected easily and without causing hardship to the people only when the weather is fair.

23,514. In the rainy season is great hardship caused to the people by evacuating them?—Yes, I think so.

23,515. Please give us an instance or two where complete evacuation stopped plague within a short time?—The following are instances:—

Chikhandigal.—Plague was detected on the 16th September, within four days after its appearance. The village was completely evacuated by the 19th November. Up to that date 180 cases occurred of which 93 proved fatal. Snbsequent to complete evacuation only seven cases occurred within fourteen days. The number of deaths did not exceed that number.

Shirur.—Plague was detected in this village on the 22nd August, ten days after its appearance. The village was almost completely evacuated before the 31st August. But owing to heavy fall of rain on the 23rd September, people living outside the village went back to their houses. They were turned out again on the 4th October. Between the 1st and 23rd September 1898, the period during which people lived outside the village, only 39 cases occurred. Between the 23rd September and the 4th October, the period during which people lived in the infected houses, as many as 59 cases occurred. After complete evacuation only 14 cases occurred within 11 days.

I may cite Kitigeri as an instance where plague having been discovered early complete evacuation stopped the epidemic within a few days. The population of the village is 614. Plague appeared on the 1st January and was discovered on the 6th. Six cases had occurred before discovery. The village was completely evacuated on the 7th. After evacuation only seven cases occurred within six days.

23,516. Have you, on the other hand, instances where cases continued to occur for a long time even after complete evacuation?—There are instances where cases continued to occur for a long time even after complete evacuation. For instance, Timmapur, Madagnur, Jantli, Dambal, Alur, Ramenhalli. In Timmapur the village was completely evacuated on the 6th December 1898, and the date of the last case is 16th January 1899. 56 cases occurred after evacuation, of which 40 occurred within 19 days. In Madagnur the village was completely evacuated on the 22nd December 1898. The total number of cases after evacuation is 32, of which 22 cases occurred within about a fortnight.

23,517. Other things being equal is evacuation less effective in stopping plague when it takes place in the rains?—It may, or it may not, be.

23,518. Can you give us any instances where the epidemic has raged in a village with peculiar severity, and if so what, in your opinion, was largely the cause of the excessive severity?—In some of the villages in the Gadag, Navalgund, and Ron talukas the epidemic raged very severely, and I think that the severity of the epidemic was due to a great extent to the insanitary condition of the houses in which the cases occurred and to personal uncleanliness of the inmates thereof. Generally the houses of the agriculturists in villages are very filthy, ill-ventilated, and dark. The argriculturists tether their cattle inside their houses and allow cow-dung and manure to accumlate in the backyards. They never keep the place where cattle are tethered clean. Owing to want of ventilation and light, the houses stink so badly that one who is accustomed to live in purer atmosphere can hardly bear the smell. Further, the villagers generally do not keep their clothes and bodies clean. Many of them do not understand how to protect themselves against contagion. For these reasons I think people living in villages suffer more than those living in towns when epidemic breaks out, if they do not evacuate their unhealthy quarters and expose their belongings to sun and air. The villages which suffered more than the others in the Gadag taluka, of which I now hold charge for plague purposes, are the following:—

Number.	Name of Village.	Population of 1891.
1	Hirehandigol	992
2	Lingdhal	1,469
3	Huilgol	1,866
4	Kadadi	1,443
5	Balaganur	1,933

In Hirehandigol cases which occurred and proved fatal between the 16th July and the 11th August 1898 were taken to be cholera cases. These cases numbered 118. As the examination of several of the patients by Dr. Barron on the 11th August showed that they were all suffering from plague, the village was promptly evacuated. The evacuation stopped the plague within about five weeks. Before evacuation 160 cases occurred including the 118 cases referred to above. After evacuation 108 cases occurred, of which 80 occurred within 17 days and 28 during the period of three weeks following the first 17 days. Out of 108 cases which occurred after evacuation, 84 proved fatal. People went back to their houses without permission about the 22nd November 1898, when it rained, but they were turned out again on the 1st December as ventilation operations were not complete. Openings were made in the roofs of all the houses for ventilation and some of the houses were disinfected with perchloride of mercury. The village was allowed to be re-occupied on the 10th January 1899, one month after the completion of the ventilation operations. A suspicious case of plague having recently occurred, the village was re-evacuated on the 25th January 1899.

The village of Lingdhal caught infection on the 22nd July 1898 from a woman from Hirehandigol. But the infection was not detected till 21st August. Within about 10 days after detection the village was completely evacuated. One hundred and seventeen cases occurred before complete evacuation, of which 85 proved fatal. After complete evacuation 318 cases occurred, of which 287 proved fatal. In no other village such a large number of cases occurred after evacuation. But out of 318 cases, 226 occurred between 3rd and 20th of September 1898. The fury of the disease during that period is attributable to heavy fall of rain during the early part of the period and subsequent cold and bleak weather. The majority of the people were inoculated by Dr. Foy when they were living in huts outside the village. More than 600 people were once inoculated and 400 twice inoculated. It may be noted that only 33 persons out of the once inoculated were attacked. But most of them succumbed. No cases occurred among the twice inoculated. The twice inoculated were allowed to re-occupy their houses after disinfection, but the once inoculated and the uninoculated occupied their houses without permission when it rained heavily on the 19th November 1898. Before orders were passed to turn out the uninoculated people again, whom I thought it necessary to keep in open air for some time longer, two imported cases of plague occurred on the 27th December 1898, and a third suspicious case of illness was brought to notice and the village was consequently re-evacuated under my orders on the 5th January. All the houses in the village were disinfected, and many of them were disinfected under the personal superintendence of the special Head Karkun, according to Mr. Stevens' kiln process of disinfection, slightly modified by Dr. Foy to suit the circumstances of the locality.

In the village of Huilgol, with a population of 1,866, both cholera and plague prevailed simultaneously. The first case of plague occurred on the 7th September.

Rao Bahadur R. R. Bhardi.

2 March 1899.

Infection was brought from Lingdhal. Between 7th and 18th September only eight cases of plague occurred. Between 19th and 22nd September there were no attacks nor deaths from plague. On the 24th September Dr. Foy examined 11 cases of sickness but was able to discover plague in only four cases. The other cases were found more or less suspicious and had all the symptoms of cholera. Complete evacuation could not be promptly effected owing to rain and inclement weather. By the 10th October 1898 a greater portion of the village was evacuated, and by the end of October it was completely evacuated. Only a small number of twice-inoculated people were allowed to stay in the village. But a large number of cases of plague occurred among the people residing in the village before complete evacuation. Up to the 10th October 170 cases occurred, and between 10th and 31st October 228 cases occurred. Altogether, 398 cases occurred before complete evacuation, out of which 350 proved fatal. After complete evacuation only 45 cases occurred within about a fortnight About 300 persons were inoculated by Dr. Foy about the 10th September, of whom 35 only were inoculated a second time. Forty-five attacks occurred among the inoculated, of which 31 proved fatal. The records do not show how many cases and deaths occurred among the twice inoculated. But I think that they were few if not *nil*.

Kadadi has a population of 1,443. This village was infected about the 22nd October. Cholera was also prevailing in this village when plague appeared. Evacuation commenced about the 1st November, but took more than three weeks owing to rain and inclement weather and obstinacy of the people. Up to the date of complete evacuation, *i.e.*, 23rd November, 244 cases occurred, of which 154 proved fatal. After evacuation 117 cases occurred, of which 103 proved fatal. The date of the last case is 28th December 1898, but the severity of the epidemic continued till the 15th December, inasmuch as 107 cases occurred out of 117 up to that date after evacuation.

Balaganur is a village of 1,933 inhabitants, and in it also cholera was prevailing when plague appeared. The village was infected about the 8th October 1898. Evacuation commenced about the 20th October, but the progress of it was retarded by rain and sowing operations. Many of the people who had vacated their houses re-occupied them when it rained heavily, and they were turned out again. The evacuation was completed on the 18th November 1898. Up to the date of complete evacuation 243 cases occurred, out of which 176 proved fatal. After evacuation 299 cases occurred within about a month, of which 222 proved fatal. This large number of cases after evacuation was due to people remaining for a long time in the infected houses, and to some of the groups of their huts being close to the infected village site, and thirdly, to their not having kept plague patients at a sufficient distance from the healthy. The necessary improvements were made by the 10th December 1898. Up to that date about 275 cases occurred after complete evacuation. After that date only 24 cases occurred up to the 22nd December 1898. For about a month after that no cases occurred. Lately one case is reported to have occurred on the 22nd January 1899, and inquiry has been instituted as to how the person attacked caught infection.

23,519. I think you have some figures to give us with regard to inoculation?—Yes. I have got some figures from a statement prepared by the village officers. These show that 433 persons were twice inoculated in Lingdhal. Dr. Foy's statement shows 443. I do not know which total is correct. 678 persons were inoculated, of whom 433 were inoculated twice, according to the statement of the special Head Karkun.

23,520. How many of those twice inoculated were attacked?—None; but one of them is reported to have died of plague about the end of December, having caught infection in another infected village.

23,521. Out of those who were once inoculated, how many were attacked?—33.

23,522 And how many of them died of plague?—30.

23,523. When were the inoculations performed?—The inoculations commenced on August 21, and continued till October 14, 1898. The second inoculations commenced on August 30, and continued till October 14.

23,524. When was the epidemic at its highest in Lingdhal?—In September. Between the 3rd and 20th September it was very furious. I find that a good many were inoculated for the first time on the 7th, 8th, 27th, and 28th September, and for the second time on the 17th, 27th, and 28th September, and 14th October.

23,525. Was any census of all the people in the village taken at any time to find out who were in the village and who had left the village after the epidemic began?—It was taken immediately after evacuation. When we detected plague I issued orders to the Mamlatdar to have a census taken in all the larger villages and have a health organisation system introduced, that is, house-to-house inspection. In this particular village a census was taken.

23,526. When was it taken?—It was taken before the 5th September.

23,527. Has any superior officer of Government tested the census?—The special Head Karkun and Circle Inspector.

23,528. Have they tested it?—On inquiry made of the special Head Karkun lately, I learn that he did not test the census in each house, but that the census was taken by the schoolmaster, with the assistance of the village officers, and that whenever he had to segregate a patient and to see other inmates of the hut and those of the neighbouring huts, with a view to detect plague, he used to refer to the census register for their names. I learn that the Circle Inspector began to visit the village in October, but I have not been able to ascertain whether he tested the census or not. The number of people living in the village shortly after the plague was detected was 1,372.

23,529. Did not a large number of those run away afterwards before the epidemic ceased?—Not a large number, I think; some went away.

23,530. What became of the uninoculated?—As many as 339 of them died.

23,531. Can you give the number of the uninoculated?—There were 694 uninoculated.

23,532. How do you arrive at that figure?—The total population is 1,372. 678 persons were inoculated, and I deduct that.

23,533. Has any superior Government officer tested the figures returned to you by the village officers with regard to the number of inoculated people attacked with plague?—The statement shows that the village officers furnished the figures to the special Head Karkun, and he communicated the figures to me. On inquiry made of the special Head Karkun lately, I learn that he used to test from time to time the registration of deaths of inoculated persons in the village, and that the figures furnished are accurate.

23,534. Has anybody gone round to every house in the village after the epidemic was over and ascertained how many of the inoculated, and how many of the uninoculated, are alive?—The village officers have a register showing the names of persons who suffered from plague, and the names of persons who died; I believe the special Head Karkun has furnished the figures taken from that register to me, but I do not know whether the houses were visited or not. I rely upon the figures furnished to me.

23,535. (*The President.*) You have several instances of villages where the cases continued to occur a long time after evacuation?—Yes.

23,536. How do you explain that failure of complete evacuation?—Because the infection which they carried from the village through their having remained a very long time in that infected area was strong. Another reason was that the weather was cold and bleak, and, of course, they had to remain in huts which were not quite waterproof.

23,537. The huts which they occupied at night were very much closed up?—Yes, and they were also not waterproof; they were leaking.

23,538. Do you think that would produce plague?—If the people were predisposed to it, then they might get fever.

23,539. Within what period of time after the evacuation did the majority at these cases occur?—The majority occurred within 17 days. After that the disease declined.

23,540. Quickly?—Yes.

23,541. You mention in your précis two villages, Dambal and Alur, and you say the epidemic took a longer time to subside than in other villages, but you think that this fact cannot be taken to establish the efficacy of evacuation. Why do you say that?—I mean the contacts and patients were not segregated.

23,542. Those segregated were allowed to come in contact with others?—Yes, I presume that the contacts and the patients were not segregated from the healthy, and the healthy suffered.

23,543. You did not therefore carry out evacuation properly?—The villages were in the charge of the Mahalkari who was acting under my orders. My impression is that the segregation of the patients and contacts was not strictly carried out, and that people visited evacuated houses stealthily. But the fact of people having remained in the infected villages for a longer time before evacuation, and the cold and bleak weather which prevailed at the time of evacuation, seem also to have contributed to the steadiness of the disease.

23,544. With reference to your cases of inoculation was there any selection whatever of the persons inoculated, or did they volunteer?—We inoculated those who offered themselves. At the beginning, of course, many did not know the advantages of inoculation, and they were unwilling, but I was there and Dr. Foy was there, and we explained the advantages of inoculation, and we induced some of the people to get themselves inoculated. Subsequently when the inoculations were done I was not present, Dr. Foy was alone there, and I believe that the people offered themselves for inoculation knowing its advantages.

Rao Bahadur R. R. Bhardi.
2 March 1899.

23,545. As a rule these people who voluntarily came forward would be the more intelligent people I suppose?—I think they are all equally intelligent. They are generally illiterate people,

23,546. There is no particular prominent intelligence?—No; I do not think so.

23,547. And the houses were all the same?—Yes.

(Witness withdrew.)

Captain A. F. C. Colomb, I.S.C., called and examined.

Capt. A. F. C. Colomb, I.S.C.

23,548. (*The President.*) You are a member of the Indian Staff Corps?—Yes.

23,549. How long has your plague experience extended?—From the 13th of November 1898.

23,550. (*Mr. Hewett*) Have you been employed in the Dharwar district ever since then?—I was in the Dharwar district the whole time.

23,551. Employed in the villages?—In village work altogether.

23,552. In what taluka?—In the Hubli taluka from the 13th November to the 13th December. I was then transferred to the charge of the Dharwar taluka.

23,553. Have you formed from your observations any opinion as to how the Hubli taluka and the Dharwar taluka respectively were infected?—It happened before my time, so I could hardly do so. Looking back to the village registers before the staff was properly organised it seemed to me that the records were not trustworthy. I tried to trace plague back, and I found that it was not worth doing.

23,554. Do you think the people from Dharwar town infected the Dharwar taluka?—I think it is undoubted in some cases. The Patel at Gadag (infected, 26-10-98) told me that many people from Dharwar came there and died of plague, but that was before my time. There were no villages infected by Dharwar since I took over the charge.

23,555. You had no work to do in Dharwar town?—No.

23,556. Have you paid attention to the possibility of infection by means of rats?—Yes, I have gone into that as closely as I could.

23,557. Have you found any instances in which rats began to die in a village without the possibility of the village having become infected by human beings, or by clothes brought by a human being?—No, not in any of the villages in my charge. In all cases there has been someone from the village, more often than not a member of the household where a mortality of rats occurred, who had been to an infected part.

23,558. Can you give specific instances of persons who had been to an infected place, and in whose houses the mortality among rats subsequently began?—I can. I take Halé Tegur as an instance. Halé Tegur is on the Belgaum district boundary, up in the north-west corner of the taluka. The village of Tegur, just about one and a half miles away, had plague. A Mahar of Halé Tegur used to go and work in the Kulkarni's house in Tegur and the Patel and the Kulkarni made no objection. A mortality among rats occurred in the Mahar's house in Halé Tegur. This village had to be evacuated.

23,559. Have you any other case?—I can give a case which is not in my précis, that of Mandihal (infected, 21-2-99). The first case of undoubted plague was that of a woman. Her huband was connected with police duties, and used to travel about somewhere near Dharwar, I could not discover where. A mortality among rats occurred in that house. The plague case was said to have been on the 10th, but the date had not been exactly recorded. A dead rat was found in the same village on the 10th, that was certain.

23,560. (*The President.*) I notice you use the term "rat-fall" in your précis; would one dead rat come under that category?—There may have been one dead rat in a house, but two or three is more general.

23,561. (*Mr. Hewett.*) When you found two or three dead rats in one house did it generally happen that other dead rats were found in the village, or not?—Almost invariably.

23,562. Does the rat mortality ever become very large?—That I cannot tell because the village is evacuated before we would be able to see it.

23,563. How long after the rats begin to die, does local infection among human beings begin to occur?—I worked it out at about three days.

23,564. From how many villages are your figures taken?—22.

23,565. What is the maximum period between the two events?—10 days according to the register, but the dates in it are not trustworthy; infection in this case occurred before my time.

23,566. What is the maximum you have seen yourself?—The maximum which I can be pretty certain about is six days. These rat mortalities are taken from reports by my native assistants who have to report them, and of course they may be wrong.

23,567. And the minimum?—The minimum is put down as one day.

23,568. May we take it that it is always possible that a rat mortality may not have been observed at first?—That is quite possible.

23,569. So that the intervals may be greater than your facts would give?—Yes.

23,570. Have you had some villages which have been infected without there being mortality among rats?—Yes, there have been cases.

23,571. Are such cases rare in your experience?—There are one or two cases noted. At Kabenur there was no mortality among rats before the plague appeared because plague was brought into the village by an imported case with plague on at the time. It was called an indigenous case in the report, because the man was a member of the village.

23,572. This would be in accordance with your idea that the origin of plague in a particular village is importation from outside by human beings?—Absolutely.

23,573. Were there any other villages where you had no mortality among rats?—Yes, Kotbagi, and Kallur.

23,574. In each of these villages was the first case of plague detected that of a person who resided in the village, but who got infected outside?—It was.

23,575. Have you noticed anything with regard to the virulence of the attack in these three villages compared with any other village in which rat mortality did precede local cases?—Decidedly; the infection was less general.

23,576. What inference would you draw from that?—That if the rats had had time, they would have made the infection more general, and the percentage of deaths would have been much higher,

Capt. A. F. C Colomb, I.S.C.

2 March 1899.

23,577. Your inference is, that having been able to put your finger on the place where the plague first occurred, your measures for stamping it out were more effective?—Yes, because infection had not been disseminated.

23,578. In addition to these three villages in which there was clearly no mortality among rats, there were a certain number of villages in which you were not able to definitely ascertain that there had been mortality among rats?—Yes, I have noted five cases.

23,579. In those villages was the mortality severe among human beings?—It was very light.

23,580. In those cases, do you think it possible that you also got hold of the first case?—I think I must have.

23,581. But you cannot say whether they were cases of local persons who got infection elsewhere?—I cannot say for certain, as I did not inquire into the origin of the disease here, but I have very little doubt that infection was from outside.

23,582. Can you say whether prompt evacuation has had a good effect upon the virulence of plague?—Yes, it has.

23,583. Can you give us figures to show that?—I have cases of eight villages which were evacuated before the first case occurred; that means that there had been a mortality among rats, and the village began to go out before the first case occurred. The average death-rate in those villages was 1·10 per cent. up to the 10th day after complete evacuation.

23,584. At your examination of those villages, were you able to satisfy yourself that there had been no plague cases before you took the people into camp?—Yes, in most cases, from the birth and death registers. There are five villages in which it commenced one day after the first case, and the average number of attacks up to the 10th day after evacuation was complete was 1·11 per cent. There were four villages in which it commenced two days after the first case had occurred, and the average attacks up to the 10th day was 1·84. I omit Kallur, because I feel sure that here the disease was cholera and not plague.

23,585. Will you specify the total population of each of the following groups:—1stly, the villages which were evacuated before there was any case; 2ndly, villages which were evacuated one day after the first case; and 3rdly, villages evacuated two days after the first case?—The total populations are as follows:—

1st. Villages commencing evacuation before the first case occurred - -	14,868
2nd. Villages commencing evacuation one day after the first case had occurred - - -	5,194
3rd. Villages commencing evacuation two days after the first case had occurred - - - -	3,448

23,586. Can you furnish any figures which show a higher incidence of attack among places in which evacuation was not prompt?—From my own experience I give three villages in the Hubli taluka, Unkal, Shirguppi, and Yerguppi.

Unkal.—Infected 11th September 1898:—
Evacuation commenced about 1st November 1898.
Evacuation completed 19th November 1898.
There were 487 attacks up to the completion of evacuation, and subsequently only one attack up to 11th December 1898.

Shirguppi.—Infected 14th October 1898:—
Evacuation commenced about 1st November 1898.
Evacuation completed 28th November 1898.
There were 130 attacks up to the completion of evacuation, and subsequently only 10 up to 10th December 1898.

Yerguppi.—Infected 28th September 1898:—
Evacuation commenced about 1st November 1898.
Evacuation completed 29th November 1898.
There were 456 attacks up to 29th November 1898, and three between that date and 10th December 1898.

23,587. Will you give the population of each village?—Unkal, 3,915; Shirguppi, 1,919; Yerguppi, 1,702.

23,588. Have you had any villages in which the mortality among rats occurred without subsequent deaths from plague among human beings?—Yes. Seven villages have been noted as having been immune through timely evacuation, although there had been mortality among rats. There are, in addition, some 20 villages in the taluka which were evacuated by reason of high mortality, or their being in the neighbourhood of infected areas which have, so far, escaped infection.

23,589. What does your experience enable you to say as to the advantage or disadvantage of evacuating villages?—I believe that rapid evacuation is everything, and I think that the mortality from plague would be less if, instead of waiting till the disease was present, whole districts were evacuated at once on plague appearing anywhere near them.

23,590. Is your experience in dealing with plague in this part of India entirely confined to the period of cold weather?—Yes.

23,591. Do you think that when the monsoon is on it would be practicable to evacuate a large number of villages?—Not on black cotton soil. It plague occurs again during the rains, I would camp the people on the roofs of flat-roofed houses. It is no hardship to evacuate villages during the rains in the hilly part of the Dharwar taluka. Here the people have built houses to meet such a contingency.

23,592. Do you think that taking the people out into the black cotton soil during the rains would cause them hardship?—It would cause them terrible hardships; I do not think it could be done at all.

23,593. Can you give us instances in which infection was carried through human beings?—I have already referred to Halé Tegur. Further instances are:—

Tegur.—Infected on 26th November 1898, by what was reported as an indigenous case. The first sufferers were two women who kept a sort of travellers' rest-house. They may have become infected through contact with their guests, but to make assurance doubly sure, one of them went to Gadag which was infected, and contracted plague within eight days of her return. The second woman nursed and slept in the same bed with the first. While these two were ill with plague, a woman from another house joins them and sits with them repairing baskets, and brings back with her some cakes, presumably from the infected house, of which she and her son partake; next day the son has plague.

Aminbhavi.—A long series of deaths from plague occur in the hut of the Timapur Kulkarni living in Aminbhavi. The two surviving members of the family are placed in a contact hut from which they abscond about the 26th January to Navalgund, where one of them promptly dies of plague, the disease having declared itself *en route*.

Tarkor (Tadkod).—Infected 24th January 1898, by what was reported as an indigenous case. The patient was a woman. Her brother was ill with plague at Khanapur, a neighbouring village, and she went to nurse him, remaining with him for two days before his death. She returned to Tarkor, and was attacked with plague within ten days of her return. The day after seizure her son was also attacked.

Kallapur.—Infected on 24th January 1899, by what was reported as an indigenous case. Patient was a woman, who on 17th January 1899, went to, and passed the night at, Alnavar, an infected village. There she bought some clothing which she was wearing when she was taken ill. Evidence was not procurable as to whose house in Alnavar she stopped in.

Jirigivad.—Infected 1st February 1899, by what was reported as an indigenous case. The first case was a trader who was in the habit of visiting all markets and infected and uninfected villages alike. The infection cannot be attributed to any certain village.

Kotur.—Reported as infected on the 4th February 1889 by several simultaneous indigenous cases. This village is a somewhat remarkable case of double infection almost simultaneously. Among the low castes at one end of the village, a house was pointed out as being the first house in the village to be evacuated. It appears that there had been a rat-fall there, and that the owner had locked the house and left hurriedly. His son had died at Navalur of plague about four months ago, and he had revisited Navalur within 10 days of vacating his house. Presumably, he brought back from Navalur some articles from his late son's house through which infection reached the rats. At the other end of the village, among the high castes, a woman died on the 30th January; she was a yarn

maker, and travelled from village to village selling the fruits of her industry. Her death was reported as fever, but there was a rumour of a rat-fall in her house on the 27th of January. A case of undoubted plague occurred in the same house on the 5th February.

These few cases may, of course, have been mere coincidences, but as inquiries into each fresh outbreak result invariably in the discovery of facts which point to human agency being alone responsible for the spread of the disease, one cannot but think that rats, monkeys, and squirrels have been accorded rather hasty condemnation. In any case the above cases serve to show the utter want of precaution, among the villagers themselves, to check the epidemic.

23,594. Is it your opinion that human agency is, in the majority of cases, the cause of infection?—It is my opinion that it is the cause of infection in all cases.

23,595. Your experience is that infection is never taken a great distance by any other agency?—That is my opinion.

23,596. Do rats move much from place to place?—As far as I can make out they never move out of the village. I have asked the question a hundred times, but I can get no single record of the rats ever leaving a village.

23,597. It has sometimes been asserted that the rats move off when there is plague; you do not think they leave the village?—No, they may run to one end, but I think they run back again.

23,598. Do you think that when a village becomes infected the rat tribe is exterminated there during the outbreak?—I think it must be. I saw a curious case the other day when I to went to dig up one of those houses to get earth from the floor to send to Bombay. There was one particular spot in the corner of a room where three people had slept who had been attacked by plague one after another. The house had been ventilated but not properly—a little light had got in. The only part of the floor which has been attacked by rats was the very place where these particular cases had occurred. Whether they had been trying to escape or not I do not know.

23,599. Are field rats ever infected?—I have never seen it myself. I give examples in my précis.

23,600. Those examples are not your own?—No.

23,601. Do you place any reliance upon them?—I think it is possible that field rats might be infected, but I do not think they spread the infection, Some native officials have told me that field rats have been infected.

23,602. Are field rats ever found inside villages?—Never inside the houses.

23,603. You do not find house rats in the camps?—Not a single example.

23,604. Have you noticed the infection among any other animals?—I have not noticed it myself, but I have had reports of monkeys.

23,605. Which kind of monkey?—The brown monkey.

23,606. Do you think that there is any reason why a brown monkey should take the infection more than the grey one?—Because the brown monkey lives about houses; he moves about the roofs, and if he can get a chance he will go inside to steal food, which the grey one will not do, being somewhat timid.

23,607. In connexion with infection by human agency, have you had any experience which would show you that particular classes have been to a large extent responsible for taking the plague from place to place?—As far as my experience goes it is the trading classes who are permitted under the "Spence Committee rule"* to travel. I cannot say that they have carried it more than other people, but in my experience they have been the people who have largely taken the disease from place to place.

23,608. Can you give us any figures with regard to them?—Referring to the likelihood of plague being spread by small traders, the following figures showing the employments of persons attacked at Gadag in December 1898, are interesting. There were in all 11 cases, of which five were traders, two goldsmiths, three females, and one was a labourer. The total number of traders in the town is about 100 in a population of between 4,000 and 5,000. It will be seen that seven of the 11 cases occurred in the travelling classes.

23,609. Do you think that it is possible by any system of passes to prevent free inter-communication from place to place?—I think it may be done in time. Free inter-communication may cease when the village officers understand its danger, and when villagers who can be absolutely proved to have introduced plague into their own village are punished.

23,610. I suppose you would mainly rely upon the people themselves, who would be desirous of excluding such persons?—Yes, we must depend upon them because we have not the staff to undertake the supervision. All uninfected villages are warned against the admission of strangers or persons from infected areas.

23,611. There is no Government agency to undertake the duty?—Not on a sufficient scale. The ward system is in force, the ward men being, as far as possible, Government servants. Nevertheless, thoroughly effective supervision is impossible.

23,612. Have you investigated in any way the question of the manner in which rats take plague about in a village?—I give an instance of the village of Kotur which was infected on the 30th of January 1899. Where plague attacks a village for the first time, I think that, given a sufficient interval for the rats to infect one another, the whole village site will finally become infected. In this district evacuation has usually been so rapid that instances of general infection of a village area are not to be had. But one interesting example of partial infection of this sort has just come to my notice. The village concerned is Kotur which has been referred to above. Here plague appeared probably about the 27th of January, but owing to concealment of the disease no steps towards a general evacuation were taken until the 7th of February 1899. Below is a rough plan of the village:—

Rough Plan of the Village of Kotur
Scale - About 1 inch = 100 yards

The houses marked black are those in which plague cases occurred, those outlined in black are those in which a rat-fall occurred. The dates given are those on which the patients died, having been taken ill probably on an average of four days earlier. The group of houses in black to the west are all inhabited by low-caste families, and those to the east all by high-caste families. In the western group house, it was the first in which a rat-fall occurred, exact date not known, while in the house just north of house B a rat-fall

* Bombay Government Notification, No. 5391/3495, dated 5-10-97) not published with the Commissioner's Proceedings.

Capt. A. F. C. Colomb, I.S.C.

2 March 1899.

occurred on the 27th anuary. In house B there was a rat-fall on the 4th February, but it was at once vacated. The peculiarity here is that the deaths occurred all on the same day in the western group, and the majority on the same day in the eastern group; the dates of seizure were not kept by the village officers, but they may be assumed to have been about four days earlier in each case. For so many houses to have become infected simultaneously other than human agency must have assisted in spreading the disease. The inhabitants of the western group are of the shepherd class, and have absolutely no dealings with the Lingayats of the eastern group. There would appear to be little doubt that rats were the agency for the spread of infection. In the map the direction of the wind has been omitted; it was due east, that is, running straight up the page, while infection travelled north and south.

23,613. Where was the infection?—There was a double infection.

23,614. On which sides of the village?—On the east and west sides. In the western part of the village infection was spread purely by rats. Infection originated through importation in the house marked A, and here mortality among rats occurred first of all, though there were no cases, because the house was at once evacuated; but deaths were simultaneous among the other houses in that part of the village, showing the infection had been evenly diffused and evidently carried by rats.

23,615. How far was the house infected upon the west side from the nearest house infected on the east side?—About 160 yards.

23,616. This interval did not get infected at all?—It remained uninfected up to evacuation.

23,617. You then evacuated the village?—Yes, on the 7th of February.

23,618. Was there no personal communication between the inhabitants of the village?—It is very possible, as in the western infected area they are all of the same caste—shepherds.

23,619. Then is it absolutely conclusive that the rats did move on the western side of the village?—No, but I deduce that they did from the similarity of dates of deaths in these houses. I do not think that these people could have collected together so as to have become infected all on the same date.

23,620. How many houses were infected on the same date?—The date of attack was not registered, but only the date of deaths; but the attacks were probably about the same period. The deaths were all on the same day in six houses.

23,621. At the eastern end of the village how many houses were attacked?—There were five houses attacked.

23,622. Did the deaths take place simultaneously in those houses?—Not quite simultaneously—they were on the 4th, 5th, and 6th February, and one attack which was not returned, but which must have been plague, was on the 30th January, giving two attacks in the same house within an interval of five days.

23,623. Would it not have been possible for this plague case on the 30th January to have given infection to the other people?—Of course, it is possible, but I do not think it is likely, because the people in the eastern group of houses were of high caste and they had no relations with the low castes on the western side.

23,624. In the particular side with which we are dealing now you have deaths on the 4th, 5th, and 6th. Could not the case which took place on the 30th have given the infection to all those people on the 4th, 5th, and 6th?—Yes, that is very likely; that might have happened. But to show that rats were spreading infection, there is the house marked B, in which rats were found dead and the people evacuating at once did not get plague.

23,625. Did they leave before these deaths had taken place?—I was there on the 7th and they were gone then. I could not say the exact day they left.

23,626. You have said that house rats do not exist in the camps. Have you been able to observe the manner in which infection is carried about in camps?—I give the example of Kotbagi to which the plan below relates:—

At the first glance this would look like local infection also, but as a matter of fact, the disease was communicated by human agency alone. The disease first appeared in the house nearest the stream which furnished the water supply of the group of huts. This case was reported as a seizure and death on the 21st January, but one of the contacts confessed that the patient had been ill for three or four days before the 21st, and that the inmates of the houses infected on the 22nd, 25th, and 27th, when going to draw water, used to come into the hut and sit with the patient. In this respect the women were the greatest culprits and it was their custom to remain with the plague patient for half an hour or more at a time. It is generally the case that in a group of villagers' huts those in which plague has occurred are close together, generally 5 to 10 yards and seldom more than 30. But for all that the locality is not infected as, more often than not, there are uninfected huts between those in which plague has appeared. Infection is spread by the people themselves, especially by the women, who cannot resist the temptation of paying a visit to the invalid just to see whether he has plague or not. There was a hut at Aminbhavi in which a plague case had occurred; the hut was emptied of all property, the patient and contacts removed, and the roof pulled off. This had no sooner been done than a relation of the patient promptly annexed the dismantled hut and used it as a cattle-shed, while he turned an unoccupied corner into a cook-house for himself.

To cite another example. A certain roomy hut at Aminbhavi stood quite alone in a field some 200 yards distant from the rest of the group. In this hut lived seven members of a family, of whom five died of plague. Two women, connections of the family, visited the patients, contracted the plague, and carried it to other groups of huts, and another relative carried the disease to another village. The original hut was vacated on the first case occurring, but the contacts did not again move when the disease re-appeared among them. As between villages, so between huts or groups of huts, the spread of infection can always be traced to human agency; and among camps it would appear that there is no such thing as infection of locality, mainly because there are, as a rule, no rats to carry infection, or because the field rats are not so liable to the disease as the house variety. Sun-light and free circulation of air are also factors to be reckoned with. It is not easy to obtain cases of the continuance of the disease in camps being due to persons secretly re-visiting the infected village site for, unless such persons are caught *flagrante delicto* they will not confess. Personally, I have only come across one case of the sort, where a villager at Shirguppi returned secretly to his house one evening, a few days after the village had been evacuated, and was found there with plague next day; he stated that he was not ill when he re-entered his house, but the truth of his assertion is doubtful.

Capt. A. F. C. Colomb, I.S.C.

2 March 1899.

23,627. Do you know whether these people got pneumonic or bubonic plague?—Bubonic.

23,628. Are you of opinion that plague can only be checked by isolating infected areas?—Yes.

23,629. How would you propose to do that?—That is a question that I have hardly thought out yet. If the villagers can be brought to understand that it is to their advantage to keep to their own villages and are punished for leaving, I think it can be managed. There is punishment for the village officers, but I do not think the mufassil plague rules lay down any punishment for the individual who introduces plague into his own village. I think such persons should be punished heavily, and that a few examples would make a great difference.

(Witness withdrew.)

Mr. J. L. Lushington called and examined.

Mr. J. L. Lushington.

23,630. (*The President.*) I believe you are in the Revenue Survey Department?—I used to be, but I am now Superintendent of Land Records and Agriculture.

23,631. You have been at Bijapur?—Yes.

23,632. (*Mr Cumine.*) You have had experience in two districts, Bijapur and Dharwar?—Yes.

23,633. Whilst you were in the Bijapur District the only place which got infected was Kaladgi, I believe?—Yes.

23,634. Where is the infection supposed to have come from?—From Sholapur.

23,635. Will you describe what was done in Kaladgi?—Towards the end of February the death-rate of the town of Kaladgi having increased, Assistant-Surgeon Mr. Redkar was sent down to find out the cause; he said there was plague, and I myself at once proceeded to Kaladgi. The place was at once evacuated, plague cases were taken to a hospital, and contacts to a contact hospital. A field census was made, and Circle Inspectors went round to find out cases every day in the fields. Disinfection was first made in every plague-stricken house and each house adjoining, and when that was finished the remaining houses (left out) in the street were disinfected and whitewashed. To the best of my recollection we did two whole streets and three or four separated houses. The rest of the town was then dry-brushed down and the houses cleaned. There were only about 26 cases in all, of which from eight to 10 took place after evacuation. Evacuation lasted until the beginning of May, when the people returned to their houses, and after return there were no cases; besides this, plague did not spread to other villages. All the roads of Bagalkot were patrolled to prevent people from Kaladgi entering secretly, Bagalkot being the large town of the district.

23,636. This was an instance of the successful stamping out of the plague?—Yes.

23,637. At its first appearance in a district?—Yes.

23,638. When were you transferred to the Dharwar district?—2nd December 1898.

23,639. What part of the district came under your charge for plague purposes?—East Navalgund and the west of Ron taluka.

23,640. How many infected villages have you under you at the present moment?—About seven or eight.

23,641. What is the area covered by them?—The two talukas join each other. The area is about 20 miles by 20 miles, or rather more.

23,642. What is your means of keeping a watch upon the mortality in the uninfected villages?—A weekly statement of deaths is sent in from the uninfected villages, and also a statement of sicknesses, which goes in weekly.

23,643. To whom?—To the Mamlatdar.

23,644. How many days after the close of the week does it reach you?—It ought to reach me the next day if I am in the same taluka. There is an extra day's delay if I am in the next taluka.

23,645. It ought to reach you on the day after the close of the week that it refers to?—It is sent in on Saturday; it would get to the Mamlatdar on the Sunday, and I ought to get it on the Monday evening.

23,646. To what extent are the people alive to the danger of admitting possibly infected people into their villages? Can they be relied upon to protect themselves against the entering into their villages of infected people?—No, they will let in relatives wherever they can.

23,647. When a village has become infected what do you think is the best way to treat it?—By prompt evacuation.

23,648. Is evacuation practicable without great hardship to the people during the rains?—In black cotton soil it would be a great hardship, but possibly in some of the western talukas, where they are more accustomed to rain, and have usually huts of their own on the borders of the jungle, it would not be such a hardship.

23,649. In what sort of soil does the plague rage most fiercely according to your observation?—In black soil.

23,650. Can you give any explanation of that?—Even now, in digging for foundations, 14 or 15 inches down the soil is found sufficiently moist to be able to make up a kind of clay balls.

23,651. So that you think it is the moisture that is the cause?—Black soil is a retentive soil, very clayey; I think that is the cause.

23,652. Have you noticed that villages along the banks of a river are more liable to infection than others?—Not necessarily, I think.

23,653. Do you find you can look thoroughly after the villages committed to your care? On an average, how many times can you visit each village?—I have to look after all uninfected villages as well. I, myself, go about once in 20 days to each village.

23,654. Do the people understand the danger of revisiting their evacuated houses? Will they boycott anyone who does it?—No, certainly not.

23,655. When a village gets infected, whom do you place there to look after it?—Whether it is infected or uninfected, it is under a Circle Inspector. He has a group of villages, some of which are uninfected and some infected.

23,656. Who remains on the spot to look after it?—Nobody except the village officers, but the Circle Inspector ought to be there directly he hears of a case, which will probably be the next day. I myself have given strict orders that they are to remain there for a day or two if plague is at all bad instead of going on to another village.

23,657. From what place did the infection of your villages come?—A tremendous number were infected before I got there. I started with 20 villages. My first weekly return in Navalgund showed 260 attacks in the 20 villages.

Mr. J. L. Lushington.
2 March 1899.

23,658. Before you left Bijapur, had the epidemic appeared in Ilkal?—No. It did not get to Ilkal for three or four months afterwards. I took it over a free district, and left it a free district.

23,659. Do you know where it came from to Ilkal?—No.

23,660. If no European remains at hand, will the people of an evacuated village obtain for themselves the full benefit of evacuation by isolating the sick persons and preventing anybody from reimporting infection from the evacuated site?—I think a European is necessary.

23,661. Have you found disinfection with perchloride of mercury efficient in destroying the germ?—I have only had experience in one place, at Kaladgi, in Bijapur, and in that one case it was successful. Since that I have had disinfection going on in my villages and two of my small towns, but the people have not re-entered yet.

23,662. Is there any other form of disinfection which you have found useful?—I am in great favour of dryness and ventilation; not a scrap of water should be in a house. My plan of ventilation has been that a strip taken off the roof in every room—the theory is a 4-foot strip, but when rooms are narrow it has been less. The chief thing, however, is the 4-foot square hole in the wall. The sun and wind gets into that, especially the latter, and creates a thorough drying draught through the hole in the wall and out of the strip in the roof.

23,663. Have you any reason to believe that that is practically efficient in killing the germs?—I have no proof of it yet.

23,664. (*The President.*) You have one case of chemical disinfection with a satisfactory result?—Yes.

23,665. What did you do besides disinfection?—We evacuated the town, and disinfected the streets in which the plague occurred. After that we brushed down and whitewashed the rest of the houses. We only disinfected certain streets in which plague had occurred.

23,666. Did you open the roofs?—In a very small way. The doors, of course, were opened out and the roofs slightly ventilated.

23,667. How long were the houses kept unoccupied?—For two months.

23,668. What was the largest village you have managed to get evacuated?—A village of 9,000 inhabitants.

23,669. Was that successful?—It had been commenced by the person whom I succeeded; it was not thoroughly evacuated. When I came down I finished it off.

23,670. You had the whole of that village out?—Yes; they are out now.

23,671. Do you think it is feasible to evacuate a larger village than that?—Yes, with a little time. The last people in a village are the most difficult to evacuate and I got all those out.

23,672. How long did you take to get out this village with 9,000 inhabitants?—It was partially done before I got there, and so I cannot say.

23,673. How long does it take to evacuate a village?—About three days per 1,000.

23,674. You mean in fine weather?—Yes.

23,675. (*Mr. Cumine.*) Are there any complaints of theft of property in evacuated houses?—They have tried to burn houses. There is no property in the villages. I have everything taken out—cotton, grain, bags, everything. There is a little loose grain left sometimes.

23,676. Have there been complaints of theft of rupees?—I have not heard of any thefts, but they have tried to burn the houses.

23,677. Have any villagers asked for disinfection?—The villagers of Nalawadi, Navalgund taluke, requested that their village might be disinfected, or that I would sell them perchloride of mercury to disinfect the village themselves. As the disinfecting inspectors were working elsewhere I was unable to accede to their first request, and I did not comply with their second as I did not like to hand over so much poison to the people.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Collector's Office, Belgaum.

SIXTIETH DAY.

Friday, 3rd March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., L.LD., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. Foy, M.B.
3 March 1899.

Mr. FOY, M.B., called and examined.

23,678. (*The President.*) You are a Bachelor of Medicine and Master of Surgery of Aberdeen University?—Yes.

23,679. In what place have you been occupied in plague work?—In Bombay, Karachi, and in Gadag Betigeri.

23,680. You have some information with reference to the value of inoculation during a plague epidemic I think?—Yes, with reference to a place not getting so depopulated; that is the point I wish to mention. The town of Gadag Betigeri in the Dharwar district consisted according to the census of 1891 of 23,000 inhabitants. This fell by the 11th of February 1899, about four months after the epidemic, to only 12,400. Gadag which is separated from Betigeri by about a mile of open land was the first part where plague broke out. Prior to the outbreak of plague about 2,500 of the inhabitants of Gadag (which nearly equally with Betigeri shares the number of inhabitants) were once inoculated, and 365 of these twice, and more would have been inoculated had not the supply of serum failed them. With the appearance of plague there was a further rush for inoculation and a large number were inoculated before the epidemic had taken a very strong hold, and to prevent having themselves evacuated from their homes. A month after the epidemic had appeared the numbers of the inoculated were doubled, nearly

3,250 having undergone single and 1,720 double inoculation, and even these numbers would have been greater but for the short supply of lymph at that time. The epidemic began to spread in Betigeri about two months after its start in Gadag, although sporadic cases had already occurred there, the number of those who were once inoculated in Gadag Betigeri now being 6,179 and those twice inoculated 5,686. By this time the disease had got to its height at Gadag. The residents of this part of the town being mainly agriculturists had moved to huts erected on their fields, partly voluntarily and partly as a result of plague measures, (those who moved voluntarily included some of the inoculated), so that Gadag on the whole presented a very empty aspect. Many of the shops were closed, the Marwaris all left the town, the agriculturists were encamped on their fields, and the tradesmen and bankers had left for other uninfected places. Betigeri on the other hand learned by the example of Gadag. The people in it were mostly of the weaver class and although their work has suffered in the general panic it has not been entirely stopped. The people of Betigeri made a great rush for inoculation and thus avoided the general evacuation of the town by getting all the inmates of their houses inoculated. The consequence is that the main street of Betigeri has already presented a busy aspect, the shops remaining open, and some amount of trade is carried on. That the greater part of this good result may be put down to the feeling of safety produced by inoculation is shown by the fact that of the 12,426 occupants of Gadag Betigeri on 11th February 1899 as many as 11,703 were inoculated, 10,994 being twice inoculated.

23,681. Can you go further, and give us any facts which will show whether in addition to the checking of panic the spread of the epidemic was appreciably affected?—I am sorry I cannot give any opinion with regard to that point.

23,682. You have had a good deal of experience of hospital treatment?—Yes.

23,683. Were you in charge of some hospital?—Yes, of the Plague Hospital at Gadag.

23,684. Had you any opportunities of seeing whether the friends who attended the patients in the hospital became affected?—Of all the friends only three were affected.

23,685. Whether they were inoculated, or not inoculated?—Quite so. We had three cases amongst those who were attending on their friends. These three cases were all uninoculated.

23,686. Out of how many?—We had 334 admissions, and each patient had a friend if they liked. I suppose about 50 may not have had any friends with them. To 291 admissions we have a record of 117 friends, but all the inoculated friends were not recorded.

23,687. Had every patient one friend only, or more?—One only.

23,688. They were therefore a smaller number than the patients?—Yes, smaller; and there were three attacks among them.

23,689. In reference to the hospital servants did they become infected?—We had no attacks among them.

23,690. Were they inoculated?—The majority of them were, but not all.

23,691. Can you distinguish the numbers of those who were and those who were not?—There were six out of 23 who were uninoculated, one was once and 16 were twice inoculated.

23,692. How many out of the total admissions died within 24 hours after admission?—Sixty out of 334 died within 24 hours of admission into the hospital.

23,693. Have you any facts as regards the incubation period from your experience with the segregated contacts?—I have worked this out by adding the number of days after admission to the contact camp that the contact took the plague, and adding that to the number of days before their admission that their friend in the house had been attacked, that is to say I add together the number of days during which the contact was exposed to infection to the number of days within which he developed plague after his admission to the contact camp. I got the following figures:—

1 day	1 case.
2 days	2 cases.
3 days	1 case.
4 days	5 cases.
5 days	2 cases.
6 days	3 cases.
7 days	5 cases.
8 days	4 cases.
9 days	1 case.
10 days	1 case.
11 days	2 cases.
12 days	2 cases.
13 days	1 case.
16 days	1 case.
17 days	1 case.
18 days	2 cases.

If the time after admission to the contact camp which the patients took to develop plague in the above is taken, I get the following figures:—

1 day	1 case.
2 days	6 cases.
3 days	5 cases.
4 days	6 cases.
5 days	10 cases.
6 days	2 cases.
7 days	2 cases.
8 days	1 case.
9 days	1 case.
10 days	0 case.

This method alone does not eliminate the fact that the patient may have been exposed to infection and undergoing incubation some days before admission to the contact camp, whereas the other method quoted is open to the objection that the patient may have received infection from other persons than his friend. On the whole, however, it is unlikely that he should get infection from others than those in whose company he is constantly found.

23,694. What have you to say about the reduction of mortality under treatment in the inoculated, as contrasted with the uninoculated persons?—In the uninoculated 29 per cent., that is 54 out of 184 recovered. Among the once inoculated we had 17 out of 32 recovered, giving a percentage of 53. There were six per cent. still under treatment when these figures were taken.

23,695. Still in a precarious condition?—They were still under treatment in hospital; they had not recovered. Among the twice inoculated 34 out of 75 recovered, being a percentage of 45. 21 cases were still under treatment, making a percentage of 28.

23,696. What have you to say with regard to the clinical aspect of plague among the inoculated? Is there any difference in the case of the inoculated patient as contrasted with the non-inoculated patient?—Yes. The symptoms are of a milder type. Symptoms such as delirium, moreover, are not usually met with in the inoculated. Delirium occurred in 99 out of 184 uninoculated cases, nearly 54 per cent.; while among 107 inoculated cases only 24 had delirium, or 22 per cent. Of the 75 twice inoculated only 17 had delirium, while of the 32 once inoculated, only 7 suffered with it.

23,697. What have you to say with regard to the almost complete absence of evil effects of inoculation which you mention in your précis?—Practically, that evil effects have been almost absent. There are a few evil effects of inoculation, of which I have some notes here.

23,698. What were the chief evil effects?—In a few cases prolonged fever.

23,699. Of how many days?—About 10 days after inoculation.

23,700. A continued fever for 10 days?—Yes, a low fever of 100 or 101. In some there was hyper-pyrexia, and in some vomiting.

23,701. With regard to the hyper-pyrexia, that was not long continued?—No.

23,702. What do you mean by hyper-pyrexia?—Over 103 or 105.

23,703. Hyper-pyrexia, as you well know, is a very serious condition. At what temperature do you term it hyper-pyrexia?—The general experience has been that anything over 103 is not what usually occurs after inoculation.

23,704. Is it an abnormal height? I should not term it hyper-pyrexia, because that is very serious. In how many cases did you have a temperature above 103?—Two.

23,705. In those two cases what was the maximum temperature?—105.

23,706. How long did it last?—About the usual time, two days. Of course, ordinarily, pyrexia is not termed hyper-pyrexia till it reaches 107.

Mr. Foy, M.B.

3 March 1899.

23,707. What other evil effects did you notice?—Severe pains in the muscles and joints in two cases, very severe pains, and they had to lay up for three or four days. There was severe purging in two cases; and at the time of the operation fainting has been observed more in men than in women.

23,708. Have you encountered plague in the same person more than once?—One case.

23,709. How often?—Two attacks.

23,710. Would you give us a few facts about that one case?—This case had come from an infected house in the town. This woman, a Brahman, and the wife of a local pleader, first came to the hospital from an infected house in the town. She then had a small bubo in the right femoral region. A relative of hers had died in the house, and another was brought into the hospital. All were twice inoculated.

23,711. Were these relations living in the same house?—Yes. Her symptoms were of the mildest, the fever having subsided before admission to hospital, and never rising above normal again, except the afternoon of the second day, and she left the hospital in five days, the bubo subsiding entirely under local treatment. She then continued well for eight days, when she was re-admitted to the hospital with a bubo in the right axilla.

23,712. Have you a clinical chart of this case?—Yes. I have the admission and re-admission chart. The original chart is not complete as the patient had some fever prior to admission. The highest temperature recorded each time was 103.

23,713. Did the patient remain in the hospital in the interval between these two attacks?—No, she did not; she went away to the fields.

23,714. How long was she in the fields?—It was only eight days.

23,715. Before she left she was continuously exposed to plague, I suppose?—She was in the hospital in a separate hut practically.

23,716. Does it occur to you this might be a relapse? You would not express an opinion either one way or another?—I would say it was a second attack.

23,717. A re-infection?—Yes, a re-infection from outside.

23,718. What is your idea of the duration of the immunity produced by inoculation?—With reference to those attacked, the duration of immunity is 50 days.

23,719. After inoculation you think they are no longer safe after the period of 50 days has expired?—Yes.

23,720. Why?—Because they have come into the hospital with plague after that time.

23,721. Can you give us some special case?—There were 31 cases that came to hospital between 10 and 50 days after inoculation; 50 between 51 and 60 days; 21 between 60 and 90 days; 5 between 91 and a 120 days; 2 between a 120 and a 150; and 1 between a 151 and 180. 180 days was the maximum. There were 10 after single inoculation, and 5 after double inoculation in the first 10 days.

23,722. You observe what this may show: that the immunity may only last for 10 days, and that those who acquired plague after 10 days, were not in a position to be infected till that time; the immunity in all these cases above 10 days being lost in the 10 days. If it shows anything it shows that 10 days is the period of preservation?—That is why I ask you to take those attacked and those not attacked. If you take 100 cases out of 10,000, there are 9,900 unattacked the whole six months and longer.

23,723. Then you cannot say anything as to the period of immunity?—I can say it is over six months in the vast majority of cases.

23,724. What proportion of the people stayed in Gadag Betigeri, and what proportion went away?—The total number that have stayed is about 12,500, in the two places combined, out of a population of 23,000.

23,725. What is the total number of cases, and the total number of deaths reported among those who remained?—About 280 deaths out of 400 cases.

23,726. Have you any idea of the number of inoculated persons out of the 12,500 who remained?—About 12,000.

23,727. Practically the whole of them?—Yes. The following table gives details:—

TABLE of ATTACKS and DEATHS, with the Population on the same Date at different Stages of the EPIDEMIC of PLAGUE, comparing the Figures for the two Divisions of the Town of GADAG-BETIGERI. The greater part of Betigeri being inoculated comparatively sooner than Gadag led to its being less completely emptied.

23,728. Did you do anything else besides inoculating the people?—We evacuated the houses where plague occurred, and the neighbouring houses.

23,729. What disinfection did you do?—We disinfected the place.

23,730. Any neighbouring places?—No.

23,731. How did you treat contacts?—Those who come from the infected house are the contacts; we cleared them into the contact camp.

23,732. Have you anything to say about the occurrence of plague in inoculated and uninoculated pregnant women?—I have had six cases. Of those four were inoculated and two uninoculated. The four inoculated all recovered, and the two uninoculated died.

23,733. What was the stage of the pregnancy in those cases?—The uninoculated were three and five months, and the inoculated were from seven to nine months. One of the inoculated went out of hospital without miscarrying. The others miscarried.

23,734. Is it a more serious matter for a woman to miscarry within three or four months, as contrasted with from six to eight months? Apart from plague altogether, which is the more serious?—The later period in pregnant women attacked with plague, the earlier in non-plague cases.

23,735. (*Mr. Hewett.*) Did you keep a record of the average temperature of the 7,300 persons whom you inoculated?—No.

23,736. With regard to the three persons infected while attending on friends in hospital, can you give in each case how many days after arrival in hospital they were infected?—In one case I remember clearly it was the fourth day, another case took ill the next day, and another the same day.

Mr. Foy, M.B.

3 March 1899.

23,757. Did any of the cases occur under such circumstances that they could not have brought the infection from outside?—To my mind they must have all brought it from outside.

23,738. On account of the number of days within which they caught it?—Yes.

23,739. Have you had any experience of the kiln process of disinfection?—Yes.

23,740. Where did you try it?—In the village of Lingdhal, and very nearly the same method in Karachi.

23,741. How many houses did you try it in?—It was tried in almost every house that was disinfected in Lingdhal, and I disinfected 228 houses (some of which were large compounds, and large houses containing from 10 to 40 rooms each) at Karachi.

23,742. Did the residents of the houses do it themselves, or was there some establishment for disinfecting?—The supervisor that went out there did it at Lingdhal, and the houses at Karachi were done under my personal supervision.

23,743. After it had been done, did any case of plague occur in any house which had been disinfected in this manner?—As the people were all in the fields at Lingdhal it has not been tried there, and as I was transferred from Karachi immediately after the disinfection was finished, I have no idea how the present epidemic is affecting the houses disinfected under my supervision.

23,744. Then you have had no idea of its nature?—No.

(Witness withdrew.)

Major T. H. Hardy, I.S.C. recalled and further examined.

Major T. H. Hardy, I.S.C.

23,745. (*The President.*) You have been on plague work at Dharwar, and you have been before us on a previous occasion?—Yes, I have been examined before.

23,746. I believe you wish to say something in addition to what you have already told us?—I said I could talk about the measures adopted for the re-admission of the inhabitants of Dharwar who were out in the huts. Dharwar was partially evacuated, and about 18,000 people went away in one week at the commencement of October. They feared segregation and inoculation, and gradually by the end of November 1898, the population was reduced to 9,800 odd. They were allowed to come back provided they were inoculated.

23,747. Was that the only requirement?—That was the only requirement at first. They gradually came back at the rate of about 500 or 600 a week, provided they were doubly inoculated. A notification to that effect was posted on every door, and if any persons went into their houses without this requirement being fulfilled they were prosecuted. I had to prosecute one person, and it resulted in a conviction. Each man who came back was given a pass (produced) signed by me; and the number of persons inhabiting the house was entered on it. I have a book containing a list of all vacated houses, and I insert how long they were vacated, how long unroofed, and the date upon which the house was re-occupied, together with any other remarks, such as disinfection, &c.

23,748. What was the minimun period that a house had remained unoccupied before these people came back?—The minimum was about a month. In the interval the house had been unroofed. At first, up to the middle of December, if a house had been unroofed and vacated for a month the people were allowed to come in without disinfection, but after that every empty house, whether unroofed or not, was disinfected with percholride of mercury.

23,749. Therefore also the majority were disinfected with chemical substances?—Yes.

23,750. I think you wish to tell us the general result of this re-occupation?—The general result of re-occupation is that there have been only two cases of plague as the people came back. These were traced to importation, one from Gadag, and the other from Navalur, a village 3 miles distant.

23,751. Previously infected houses, therefore, no longer conveyed infection to inoculated persons?—They have not done so, so far.

23,752. But these houses were probably themselves no longer capable of giving infection?—I do not think so.

23,753. What have you to say about the measures adopted after the abolition of inoculation?—The people petitioned with regard to the loss of trade, so the Collector asked me to frame rules for the re-admission of the people from the huts around. I had a census taken of all the people as far as I could get them. It took from the middle of December until the end of January to get. 8,148 people were found in the huts. I went round myself occasionally with the Hospital Assistant to find out where the plague was. We found out one or two cases, and we burned their huts. Latterly, however, there has been no plague there, and the people were allowed to come in provided they were disinfected in their huts.

23,754. They were allowed to return to their houses in Dharwar?—Yes.

23,755. Was the result different?—They were uninoculated. They did not suffer. Nothing has happened.

23,756. It shows nothing either for or against inoculation?—It shows that evacuation has done good in that case.

23,757. Have you anything additional to say about the disinfection of houses which has not already been described?—No, I have nothing more to say. We have rules now about the people coming in. Of course we can only account so far for about half the original population at Dharwar; about 19,000 people are unaccounted for. I have here the last census (produced) showing the state of Dharwar town.

23,758. The population is only about 20,000 at present?—Yes.

23,759. As contrasted with a normal population of what?—In June last the population was over 38,000.

23,760. (*Mr. Hewett.*) Where do you think that the remaining 19,000 persons have gone to?—They have scattered over the country; they are not in huts round Dharwar. I think a great many of them have died. In one set of huts I visited about a fortnight ago, on inquiries from the people I found that out of an area of

Major T. H. Hardy, I.S.C.

3 March 1899.

about four acres there were from 40 to 50 huts, and I was informed that in every hut there had been cases of plague, with one or two deaths at least in each.

23,761. These were the huts of persons who had segregated themselves voluntarily?—Those who had voluntarily evacuated.

23,762. At what distance from Dharwar town?—These huts were about a mile from Dharwar, on the main road between Hubli and Kalghati.

23,763. At the present moment, could these 19,000 people come back without being inoculated?—That has been stopped. I have the orders here (produced) which are at present in force.

23,764. For how long have they been in force?—It has not yet been sent round the districts: I did not like to circulate it until I had the people in from the huts around.

23,765. Upon what terms are you going to re-admit the people?—I have had a notification published by the Collector of all the plague-infected places, and we have a system of guarantors for arrivals coming into force. Uninoculated persons coming from an infected district who cannot get a guarantor will be sent to the health camp. Those who are inoculated will be allowed to go at once.

23,766. Whether a person comes from an uninfected place or from an infected place, he will be allowed to occupy his house if he has a guarantor?—Yes. But his clothing is disinfected, should it be dirty, or if the volunteer at the railway station thinks he is likely to carry infection, his clothing is disinfected.

23,767. In your opinion what proportion of the Dharwar population that left the town occupied huts in the neighbourhood of the town?—One-third.

23,768. How many people would that leave to scatter themselves about the country?—About 19,000. I do not know how many of them are dead.

23,769. Do you consider that those 19,000 persons did scatter plague throughout the Dharwar district?—Yes, certainly. I do not say that all the 19,000 persons scattered the disease, but some of them must have done so.

23,770. In all probability they were very badly infected?—Yes; I know that a great many infected people went to the villages round about, and did scatter plague.

23,771. Do you keep the keys of the locks on the vacated houses?—No; we paste up a notice that the people are not to go into a particular house. We paste the notice over the lintel of the doorway, so that it cannot be opened without breaking the notification. The case I brought before the Magistrate had a very salutary effect, the people come up readily and asked for re-admission.

23,772. Do you now think, at Dharwar, that, provided that a house has been properly disinfected, and that the person returning to it is not likely to be himself incubating plague, or to be carrying the infection in, it is quite safe for him to come back to his house?—I think the results show that.

23,773. That is to say the authorities at Dharwar now attach more importance to disinfection than they did?—Yes; I think they do. It has been disinfection combined with evacuation of the houses. All the houses have been unroofed as well.

23,774. Your treatment of the houses, whether by unroofing them, or by opening them out and disinfecting them, has, in your opinion, destroyed the local contagion?—Undoubtedly; I do not say whether it is due to disinfection or the emptying up of the houses. The combination of the two has done it, I should think.

23,775. (*Mr. Cumine.*) To what extent have the people been now converted to believe in disinfection?—I do not know about belief in disinfection.

23,776. I am referring to chemical disinfection?—My own opinion is that the people had a lot of trouble owing to being kept out of their houses. When they heard they could come back without inoculation provided their houses were disinfected, they would have all come back in one day if they could. According to the rule, however, they were not allowed to come back until their houses were disinfected. I had any number of petitions from people asking me to disinfect their houses. I do not know whether they believe in disinfection or not. I should think it is probably the other way, but that they accepted disinfection as a means of re-admission to their houses.

23,777. (*The President.*) Have you had any experience of disinfection without chemical disinfectants, such as opening of houses?—Yes.

23,778. Can you give the result with regard to the destruction of the virus?—In Kelgeri, about 3 miles away from Dharwar, I had all the houses opened, the roofs taken off, and the doors taken off. Besides that I have had all the ground in the rooms dug up to the depth of about 3 inches and thrown out into the sun. The people themselves willingly came forward and lime-washed their houses. They have all gone back now, with no return of plague.

23,779. How many people or houses does that instance deal with?—One village of about 1,000 inhabitants.

23,780. You did not use mercuric chloride?—No; nothing.

23,781. Are these inoculated persons?—There were eight families incoculated in the village, and they have been occupying their houses all the time.

23,782. The majority were uninoculated?—Yes.

23,783. In the case of Dharwar, had you, before this large exodus took place, made any provision for the people who wished to leave the town?—There was only one health camp in the town capable of holding 1,000 people.

23,784. Therefore, of course there was no actual measure in operation which would prevent their scattering themselves?—The only measure was that the Goverment of India allowed them to get bamboos at about a quarter price to build huts with outside the town. There was a depôt at the Dharwar station for that purpose.

(Witness withdrew.)

Major R. H. Forman, R.A.M.C.

Major R. H. FORMAN, R.A.M.C., called and examined.

23,785. (*The President.*) I believe you are in the Royal Army Medical Corps?—Yes.

23,786. I understand that you have volunteered to bring before us some cases in which inoculation appears to have produced good effects?—Yes.

23,787. Will you kindly state what you wish to say?—There were two groups of cases that I inoculated when plague first broke out in Belgaum with whom I have been able to keep in touch since. The two groups were amongst my own private servants in my own bungalow, and my hospital attendants with their wives and children in the Station Hospital at Belgaum. Of my private servants there were in all, including their wives and children, 28 people inoculated. There have been no cases of plague, and no deaths up to date. There were three uninoculated. One was a child of nine years of age, whose father refused to allow it to be inoculated. It died of plague 12 days after the other people were inoculated. I diagnosed the case myself as plague.

23,788. How long after?—The child got plague and died 12 days after the servants were inoculated. They were inoculated in December 1897.

23,789. The child was not ill at the time?—No, it was perfectly well. The other two cases that were not inoculated were not so distinctly under my own observation. One was a sweeper employed in the Cantonment as a Municipal sweeper, the husband of my sweeper woman, and sleeping in my compound. He, I am told, died of plague some months afterwards. He was not inoculated. The other was my bhisti. He threw himself into a well. I was informed that he had buboes and fever, and ran away to escape segregation. Of the 28 inoculated none died of plague, and of three uninoculated two are said to have died of plague, and one undoubtedly died of plague.

23,790. Were these people living in the compound?—Yes, except the bhisti.

23,791. How was the infection conveyed to the people; how did they become infected?—I do not

know. Plague was raging in the bazar close by. The bungalow was within a quarter of a mile of the Sadr Bazar.

23,792. Were there any rats?—There were rats about the bungalow, but I did not see any dead rats. All around the bungalow there were cases of plague and deaths.

23,793. Where were the servants living?—In my compound. I disinfected the houses myself.

23,794. When; at the time of inoculation, or before or after?—I do not know whether it was before or after. On further consideration, I am sure the houses were disinfected both before and after.

23,795. So that in addition to inoculation there was thorough disinfection?—Yes, they were all slushed down with perchloride of mercury, and the roof taken off.

23,796. Presumably the originally infective cause had been removed by disinfection?—Possibly so. I may mention that amongst my servants I found there was one woman who was inoculated who had died in a village, but it was said not to be of plague. I know that the woman many months before was the subject of malarial fever. She had an enlarged spleen and an enlarged liver. I know that from my own observation. I hesitated whether I should inoculate her at the time I think the statement that she did not have plague is true.

23,797. What other instances have you?—My hospital servants. These are under my own supervision. There were altogether 87 inoculated, of which 79 were continually resident in the place. Eight were there during the day only, and went home at night.

23,798. What was the total number of hospital attendants?—Ninety. Eighty-seven of these were inoculated. Since then of the inoculated (87) there has been one death, a daughter of one of the men, but she did not die of plague. She died of rheumatic fever and endocarditis. Of the three who were not inoculated, two were not inoculated because they were pregnant, at least, one had recently been delivered, and the other was pregnant. The third was a boy sixteen years of age, whose father refused to let him be inoculated. One of the uninoculated women has not had plague, she is alive now. The boy whose father refused to let him be inoculated died of plague on the 22nd February 1898, less than two months after the other people had been inoculated. The other woman died on the 24th of February, 1898. She also died of plague. She had been in attendance upon the boy.

23,799. Therefore two of these three died?—Yes. There were only three uninoculated, and two of them died. The houses were then evacuated for ten days, and disinfected. The people went back to them, and there has been no more plague in them since.

23,800. These houses, however, were occupied by 87 inoculated and three uninoculated people?—No. Eight of the people that were inoculated did not live in the houses. Seventy-nine of the inoculated, and the three uninoculated were always resident in the place.

23,801. When did these plague cases occur, nearly at the same time, or at different times?—One death took place on the 22nd of February 1898, and the other on the 24th of February 1898, two months after the other people were inoculated. The inoculation date was the 28th and 29th of December 1897.

Major R. H. Forman, R.A.M.C.

3 March 1899.

23,802. (*Mr. Hewett.*) Referring to the first group (28 cases), did the disinfection of your vacant houses take place before the child that died of plague took plague?—Yes, they had been disinfected before, several times, I think, but once, I am certain.

23,803. How many other residents were there in the particular house in which the child died of plague?—Three, father, mother, and the child. The child died in the segregation camp. The father and mother were allowed to go with it, but returned immediately after its death, and lived among the rest of the servants.

23,804. Among the people that you inoculated were there any persons over the age of 50 or 60?—Yes, two. One in the 28 group and one in the 87 group. The former was the father of my cook, an old crippled man; he is alive and well now. The latter was the mother of one of my hospital attendants. She left eight months ago, and died in Madras some six months ago. The cause of death is unknown to me, but her son states it was not from plague. I understand there was no plague in Madras six or eight months ago.

23,805. In the group of 28, how many under the age of three did you inoculate?—There was one of two years of age, and two of four years of age. Of course the ages are approximate.

23,806. There were three under five?—There were three under five years of age.

23,807. The old woman was the only person among the inoculated in the group of 87 who has died?—That is the only death among the inoculated.

23,808. How many of the inoculated persons were under five?—I have not got the ages; I do not know, six at least.

23,809. Were any rejected because they were too old or too young?—No, none were rejected. We gave graduated doses according to age, sex, &c. My observations are summarised as follows:—

1st Group.—28 inoculated; 3 not inoculated.

Of the inoculated, one woman died in her own village several months afterwards. The cause of death is unknown, and said not to be plague, and the woman was a confirmed invalid. The others all well now, and have not suffered from plague.

Of the uninoculated, all died, one 12 days afterwards of undoubted plague, the other two of what was said to be plague. One of the latter did not live in the compound.

2nd Group.—87 inoculated; 3 uninoculated.

Of the inoculated, one died some months thereafter of rheumatic fever and endocarditis, and one woman died in Madras six months ago, but not of plague. The others are all well, and have not suffered from plague.

Of the uninoculated, two died within two months, both being undoubted cases of plague.

Thus in a total of 115 inoculated cases, there were no attacks, and in six uninoculated cases there were five attacks and five deaths, though two of them were only hearsay cases of plague.

(Witness withdrew.)

Miss A. M. Corthorn, M.B., re-called and further examined.

Miss A. M. Corthorn, M.B.

23,810. (*The President.*) You are prepared to give us some further information as to the results of 37,000 inoculations which you have done?—Yes, they are the inoculations of Gadag. Up to the 18th February there were 20,859 people inoculated, of whom 17,997 were inoculated for the second time; that gives a total number of inoculations of 38,856. It is a little over 39,000 now.

23,811. Have you come to any conclusion with reference to these inoculated persons as to the interval which occurs between inoculation and plague?—I have worked that out for the Dharwar results, but not completely for the Gadag results; that is in process of construction.

23,812. Have you any information with regard to the dosage as influencing immunity?—I always give a larger dose than the prescribed dose, one-fifth more. When I came away from Dharwar there were 4,003 people who had been inoculated at the Civil Hospital, and 8,552 whom I had inoculated. I had inoculated more than twice as many as were inoculated at the Civil Hospital; 96 of the cases which I inoculated developed plague. A good many of those really came out because they fell within the incubation time, taking that as only 48 hours. Of the 4,003 who were inoculated at the Civil Hospital 78 got plague. Admitting all the cases, there were 96 cases amongst my 8,552 and 78 among the 4,003. In Gadag, out of the

Miss A. M. Corthorn, M.B.

3 March 1899

38,000 inoculations, I have done, roughly speaking, three-fourths, and Dr. Foy the remainder; 86 cases, so far, of the people whom I have inoculated have taken plague, and 66 of those whom Dr. Foy has inoculated. The only difference has been that I give larger doses than the other people who have been working with me. The plague incidence has been considerably smaller among the people I have inoculated than amongst those who have received the smaller doses.

23,813. Is there any relationship you wish to draw attention to between dosage and sex?—Women bear quite as strong doses as men; in fact, men react rather more than women do, that is, the higher temperatures have been observed in men.

23,814. I understand your practice is to make no difference between the two?—That is so.

23,815. Now, with regard to age?—Children get much larger doses in proportion to adults. I gave one-fifth of the dose to children under two, and got no reaction at all, and I found the same thing happened over and over again. I have no figures, but that is my general impression. When the child is brought for a second inoculation I say, "Was it bad the last time?" and the parents say, "No, not at all, he did not seem to feel it." So I have got into the way of giving a child of one year old 1 c.c. of the 2½ c.c. prophylactic, that is two-fifths of the standard dose, and a child of 12 has the standard dose.

23,816. Have you seen any case where the temperature did not rise?—Yes. I have not taken the temperatures in Gadag, but you cannot take temperatures when you are doing nearly 1,000 inoculations a day. The temperatures were only taken of those few cases at Hubli, regarding which I have submitted notes. (*See* Question No. 1,778.)

23,817. There is an enormous number of other cases where the temperature could not be taken?—Yes. I can only state the general impression that I have received by asking people at the time if they were bad at the first inoculation. I have made a practice of that. I am also working out a table, which is not yet complete, in regard to the interval between the first and second inoculation. I think that bears somewhat on the severity of the first reaction. I take it that a person who has had a very bad reaction will not be in a hurry to present himself for a second inoculation.

23,818. You have met with instances where there was no particular rise of temperature?—Yes.

23,819. Do you know whether any of those persons became infected?—There were no cases of plague among those people, but they were inoculated when plague was going down. They were inoculated in the Southern Mahratta Railway Lines in Hubli, and although there had been cases there before there were not cases after that time amongst the uninoculated. There were only a few uninoculated, but the plague had gone down very much. Therefore, the inference that those people who did not develop a temperature were still protected cannot be drawn.

23,820. In the case of second inoculations, did you have the same temperature reaction or a different one?—The general result was that the temperature was about the same. In a few cases I thought it was higher, that those who got it lower first got it higher afterwards; but when I worked out the figures it seemed about the same. Having a slight reaction the first time did not mean that they would have a big reaction the second time, and if they had a big reaction in the first place it did not follow that they would have a weak reaction in the second.

23,821. You did not have, in the second inoculation, cases where there was almost no rise?—No, not one.

23,822. It was exceptional to get only a low temperature?—Yes.

23,823. Were those people who were inoculated twice and who did not have a large rise of temperature equally protected?—I cannot say. I think the time at which the inoculations were done prevents one drawing any inference. I know they did not get plague, because I was able to follow them up; but plague was going down in that particular quarter of the town, and the inoculation may have had nothing to do with protecting them.

23,824. Have you done any third inoculations?—I have done some.

23,825. What was the temperature?—I have not been able to follow that up. They are people who come up to me in crowds. A good many people have asked to be inoculated a third time.

23,826. What is your opinion of the relative value of single and double inoculations?—In Dharwar it worked out largely in favour of double inoculations. We had a difference of 30 per cent. in the reduction of morbidity for the doubly inoculated, and about 18 per cent. in the reduction of mortality.

23,827. Have you got any further evidence on that point? Your case remains as it was before?—That is so. In Gadag, at present, it is not working out so largely in favour of the doubly inoculated as it did in Dharwar. The number of once inoculated present at any time as compared to the twice inoculated is so small that the comparison is a less valuable one than if they were present in about equal proportions. These charts* illustrate that, perhaps; they show the relative proportions of the three classes resident in the town, and the plague incidence among them.

23,828. You mean the three classes of once inoculated, twice inoculated, and uninoculated?—Yes. The black line represents the uninoculated, the blue line the once inoculated, and the red line the twice inoculated. The uprights give the proportion of cases in the corresponding column.

23,829. You have formed no opinion of the relation between the degree of temperature rise and the efficacy of the inoculation?—I have no figures on the point, but I have seen nothing to lead me to think those who have not reacted to the prophylactic are more apt to take the disease.

23,830. You are not in a position to say that, even independently of temperature rise, the efficacy may be the same, being rather the result of the dose, or the quantity, than of so-called reaction?—No.

23,831. (*Mr. Hewett.*) With reference to the statement prepared from the weekly reports which you have put in in your previous evidence, can you give us figures for Gadag which correspond with those given for Dharwar?—Yes; I have worked them out rather on different lines. I have tables prepared, as follows:—

STATEMENT from the WEEKLY CENSUS of the NUMBERS of UNINOCULATED, ONCE INOCULATED, and TWICE INOCULATED present in GADAG TOWN.

Week ending	Uninoculated.	Once Inoculated.	Twice Inoculated.	Total Population.

23,832. Was a census taken of Gadag, or have you taken the assumed population from the census of 1891?—A special census was taken in November or December 1897.

23,833. Who took the census, a European or a native?—It was taken under the direct supervision of Mr. Vincent, who was in close personal touch with almost all the people in the town. He threw himself very heartily into the work. He was the Chief Plague Superintendent, and he superintended the whole of the census; he did not go round to the different houses, but he did really know the people in Gadag and Betigeri.

23,834. The population was found to be 25,069?—Yes.

23,835. Subsequently the weekly population recorded in this statement declines week by week; can you tell us how it has been calculated?—Yes. Every Saturday morning the Superintendents of the districts went round. They kept the books of the number of people in each house, and they went to each house and saw how many of those people were present in the town at that time, and examined their inoculation checks, or passes, and only those were put down as doubly inoculated who showed a double inoculation certificate; and only those were put down as singly inoculated who showed a single inoculation check. That they did look at these certificates is indirectly proved in this way, that after the weekly census was taken people came up to have any slight errors in their certificates, which they themselves had not noticed, rectified. There is always a difficulty in getting a native woman to mention her husband's name. That is a very great difficulty in registration, that the wrong husband's name is registered. Each week these mistakes would be discovered by the Supervisor in going round, and the people would come up to me in the afternoon to get those errors rectified. The division into those three classes is based only upon that fact. I have never worked out any results upon the register as a whole, but on the actual numbers that were stated in this weekly census to be present in the town.

23,836. Previously by the native Superintendents?—Yes, and submitted to the Plague Superintendent.

23,837. With regard to the deaths among the uninoculated, and the once and twice inoculated, who decided in each instance the class in which the deceased person should be recorded?—The doctor in charge of the hospital, Dr. Foy. And I, myself, went to see all these cases in hospital. I went every day to look at all the cases that came in, and cross-questioned them as to whether they had been inoculated or not inoculated.

23,838. Whom did you cross-examine?—The patients, and the attendants who came with them.

23,839. They had one attendant as a rule?—Yes. Then if one could not get the information, one would go to the Supervisors of the district, and find out from them how they were entered in the book. The Supervisors get to know the people pretty well, because they go round every week and examine the checks and certificates in this way.

23,840. Were the people's addresses, as well as their names, entered in your register?—Yes.

23,841. And you have no doubt the registers are accurately prepared?—I am sure, every now and then, a slight error did come in. We had the errors of the husbands' names, for instance.

23,842. Who supervised the clerk who made the record?—I watched him the whole time myself; he was my clerk.

23,843. You were doing a lot of inoculation at the time, was it not rather difficult to combine those two duties?—Yes; it rather tired me when I did it. I had a man standing at one door to see that nobody went out without being registered. I stood at one table, and had a clerk by me who gave what I call my inoculation check to the persons inoculated. He took the fee and gave the check, which had the serial number on it. The patient who had just been inoculated walked up to the other table which was near to me, where the registering clerk sat, and his name was registered, and the name and the date written on the check. If a person did not come up with the right number he was at once stopped, because the clerk had missed one number out. I kept well on the alert, and was looking at the book every few minutes to see if he was ticking the people off in the order in which they came.

Miss A. M. Cornhorn, M.B.

8 March 1899.

23,844. Was the same care taken in registering people who were inoculated at Dharwar?—Yes.

23,845. Were you present when Capt. Leumann made his inoculations?—He did no inoculations there. At Dharwar I took exactly the same precautions; it was at Dharwar that I instituted that system.

23,846. Did you have the same system from the beginning of your work at Dharwar?—Yes, exactly.

23,847. You did a certain number of inoculations at Hubli?—Yes.

23,848. Were the Hubli registers as accurate as those at Gadag?—I had nothing to do with the registers at Hubli, but I do not think they were done so well. It was because of those shortcomings that I adopted my procedure at Dharwar.

23,849. Did you observe the inoculations carried out at Hubli by other persons?—Yes.

23,850. Did you observe Capt. Leumann actually inoculating?—Yes, I helped him.

23,851. How many persons were inoculated in the course of a day?—I could not tell you. I believe he did 700 in one day at Hubli.

23,852. At the time he was inoculating at that rate, were the registers accurately kept?—I could not tell you; I was not with him when he did those inoculations. I thought his system did allow room for some mistakes occurring, and that is why I adopted my system. I adopted some of his methods, but by always keeping the number of the person inoculated in my own hands, I think I sufficiently kept the person in touch with the certificate. A person who was inoculated twice got his certificate at the end. When he came up to me for the second time for inoculation, he presented his inoculation check, and the clerk who was by me asked him his name; he did not read out the name on the check, but the person had to give his name, and if the name did not correspond with the name on the ticket he was told he had brought the wrong ticket, and was sent back to get his own ticket.

23,853. (*Mr. Cumine.*) Why was the census taken in November or December 1897?—Because plague was expected.

23,854. Who is it that goes round every Saturday with the census book in his hand to inspect the people?—The supervisors and their clerks.

23,855. Do you mean a supervisor goes with a clerk, or do they go independently?—No; one clerk goes with each supervisor.

23,856. How many supervisors are there?—I cannot tell you; I have not done that part of the work at present. I forget the exact number of wards into which the town is divided. It is divided into six sub-divisions, but I am not sure what the number of wards is. I think each sub-division contains something like five or six wards, which would make about 24 wards altogether.

23,857. Would there be 24 supervisors, probably?—Yes, each supervisor has an average of 150 houses.

23,858. Assuming there are 25 supervisors, and a population of 25,000 people, each supervisor would have to see 1,000 people each Saturday?—That would have been so at the early part. Since a weekly census has been taken, we have never had 23,000 people there; it was 20,000, and on November the 18th, the first time the sub-division was made into three classes, it has been rapidly declining until now it is only 12,000.

23,859. Did any European officer test the work done by these supervisors on Saturday?—Yes. Mr. Vincent himself had to go round one week to one ward, and another week to another ward. He was generally out in that part of the town in which they were taking the census.

23,860. Do you mean taking the original census?—No, the weekly census. I do not say he went down with each one in particular, but he was generally supervising and seeing that the work was done correctly; they were done under his personal supervision the whole time.

23,861. Do you know whether he was testing it in the sense of taking the census register in his hand and making the people stand up in front of him?—I never saw Mr. Vincent do that, but I am quite sure, from what I know of his work, that he would have done it at several houses. He would not go to every house and do it, but that would be his way of testing it. He would go into certain houses and call the people out, and see whether the work had been done correctly in that house.

23,862. That is what you think he would have done?—Yes.

23,863. With regard to those people who died in hospital, you said that Dr. Foy was the authority to determine whether they should be registered as inoculated or uninoculated. Who was the authority that decided this with regard to the people who died in the town without going to hospital?—Dr. Foy, if he was called in; otherwise, the Hospital Assistant, whose work it was to see those cases. He saw the cases and sent in the returns, and when he was in any difficulty he referred to Dr. Foy as the Chief Medical Officer there. It was not a very difficult question to decide, because it was a question of getting a certificate from them. They were not to allow any uninoculated person to pass, because the information was not only wanted for my returns, but to decide whether the people were to go into contact camp or not. Directly a case occurred, there was an overhauling of the certificates by the officer who found the case, in order to decide which of the people were to be sent to the contact camp, because the doubly-inoculated people were not sent to contact camp.

23,864. Were the once-inoculated people sent to contact camp?—Yes, but the people were very anxious to bring up their certificates, and, therefore, no case would be likely to be missed.

23,865. I see that it was to the advantage of the twice-inoculated people to produce their certificates. But if the once-inoculated people were sent to a contact camp, what motive was there for them to produce theirs?—They do not hide certificates. Imitation has so very much to do with determining what a human being will do. When some brought out their double certificates, the others brought out their single certificates. The whole of the certificates are kept together, whether single or double, and the head of the house, when questioned by the supervisor, brings you out a roll of certificates—single and double certificates together.

23,866. How is this within your knowledge?—Because they are brought to me again and again. I have been into the houses to ask the people whether they are inoculated, and they produce these rolls of certificates in the way I have mentioned. If you go round to any town where great stress is laid on inoculation, you will find that is what they do. These people keep their certificates rolled up or mounted on bits of cardboard, and they are all tied up in a handkerchief, and the head of the family keeps them.

23,867. Have you been in the house of a once-inoculated person, after he had died, and seen the way in which the certificates are kept?—Yes.

23,868. Have you been in many?—Not many, because it was not my work; but I know the habits of the people. It is their habit to keep their certificates in that way.

23,869. I do not think you told us what the motive was for the friends of a deceased once-inoculated person to produce his certificate on the day of his death. What advantage is it to them?—One thing is this. They say, "you compel us to be inoculated, and here "is an inoculated person who has died."

23,870. What advantage is it to them?—There is no advantage, but it is a human propensity. They think that you have told them that a certain result will not follow a certain course, and when the result happens they bring you the evidence to show how it has happened. I think that is a very natural human motive.

23,871. Have people not to pay a fee for getting themselves inoculated?—Yes.

23,872. Therefore is there not a motive on the part of the brother of a deceased once-inoculated man to retain the deceased's certificate in order that he (the brother) may not have to pay a fee for getting himself inoculated?—Yes, but that is where the system of registration picks those people out. These people find every time they bring up a wrong ticket that they are sent back, and they find it is no use bringing up

another person's certificate. That is what Captain Brownrigg, who has lately been appointed our Chief Plague Superintendent, has remarked. He said that in Hubli he did find people presenting other people's certificates, but never in Gadag. Where you have a system of registration, the people are being continually reminded that they cannot cheat, or that if they do they will be found out. When their certificate is presented they are asked their name. They do not know the name on the certificate because very few of them can read, and they give their own name.

Miss A. M. Corthorn, M.B.
3 March 1899.

23,873. If A's brother has been inoculated, the name of A's brother will be on the certificate. Does not A know his own brother's name?—Yes, but he has to report his brother's name as the person who has died. The name of every member of the family is down in the supervisor's book. Therefore as A would have to give the name of his brother, who had died, as being inoculated, he cannot choose that name for himself.

23,874. Will you tell us whether your register of inoculated persons is in Mahratti or in English?—It is in English.

(Witness withdrew.)

(Adjourned till Monday, 6th March, at Sholapur.)

At The Railway Station, Sholapur.

SIXTY-FIRST DAY.

Monday, 6th March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. W. M. MUAT, M.B., called and examined.

Mr. W. M. Muat, M.B.
6 March 1899.

23,875. (*The President.*) You are a Bachelor of Medicine?—Yes, and Master of Surgery, Glasgow.

23,876. You are in an official position here?—Yes, temporarily on plague duty; special work.

23,877. You have been inspecting health camps?—Yes.

23,878. And also supervising contacts?—Yes.

23,879. Since the re-occupation of the city of Sholapur in April 1898 you have had some experience as regards the inspection of corpses, I think?—I have all the time up to the present; it is still going on.

23,880. Have you encountered any difficulties?—I do not think I have ever really; perhaps once or twice they may have said some slight thing, but I have had no serious difficulty at all.

23,881. To what extent do you inspect corpses?—Every corpse; every person who dies in the city.

23,882. Male and female corpses?—Yes, Muhammadans and Hindus alike.

23,883. Are there no pardah nashin women here?—I have not had any trouble at all. I have seen every corpse that has died for quite a year, I should think, in the city.

23,884. And no objection was raised at all?—No serious objection. There was only one case, and it was not a serious objection at all. They simply said that they wanted a female doctor.

23,885. What does your examination of the corpse consist of?—I examine the eyes and tongue, the situation of the lymphatic glands and the general appearance of the face.

23,886. You examine the groins, for example?—Yes, the groins and the axillæ.

23,887. Have you been here all the time of plague at Sholapur?—I came here in the first or second week of December 1897.

23,888. When did plague commence in Sholapur?—I came here just at the height of the epidemic. The epidemic started on the 23rd of September 1897.

23,889. Did you find when you came that the measures to eradicate the plague were already in operation?—Yes, they were.

23,890. What were the measures?—The removal of plague cases to the Plague Hospital and the segregation of the families in which the cases had occurred; then there was evacuation of the city; and then, after the city was evacuated, the houses were all disinfected with chemicals, and thrown open, holes were made in the roofs and walls, and all filth was removed from the houses and streets, and alleys and courts, and burnt. The city had a thorough clean up, I should say.

23,891. Were all these measures adopted simultaneously?—Of course the disinfection took place when the city was evacuated.

23,892. But the other measures?—The first three measures were concurrent, and then the disinfection and the burning of dirty rags took place. The city was evacuated, and the filth removed.

23,893. I understand first that the evacuation was only in parts?—Yes, it was at first only partial. The epidemic started in a small suburb of the city, the Sadr Bazar, just about a mile and a half from the city. It is situated between the European quarter and the city. The plague started in the European quarter, amongst the servants of the Europeans who were living in camp. Then it was carried by the servants, I presume, down to the small Sadr Bazar. One man was found suffering from plague in a temple in the Sadr Bazar, one of the original household that was attacked. He was found in the temple sick of plague.

23,894. At first you evacuated that part in which cases occurred only?—That was evacuated first. The city was commenced to be evacuated in October 1897, and it was completely evacuated by the end of December 1897.

23,895. Before any evacuation took place, was there any segregating of the affected and their contacts at the very commencement?—I do not know really, as I was not here when it started.

23,896. When you were here evacuation was proceeding, in the first place, in affected areas?—The original infected area had been evacuated when I came here.

23,897. Had any subsequently infected area been evacuated?—When I came here they were just commencing to evacuate the real city.

Mr. W. M. Muat, M.B.

6 March 1899.

23,898. Do you know why they did not content themselves in evacuating a limited area?—The plague had commenced in the real city, in Sholapur.

23,899. When plague appeared in the true city, they started to evacuate the whole city?—Yes.

23,900. And that took from October until when?—Until the end of December, from the 26th of October till the 31st of December.

23,901. That is rather slow progress, is it not?—It is a rather large city, 63,000 people, to make arrangements for people going out into camp; you cannot do it all in a week.

23,902. You had 60,000 people to deal with, had you?—No, I should say about half the population, 30,000 or so.

23,903. And to evacuate 30,000 people, you think you would require about two months?—I should think so, quite. You did not know that the houses that the people fled from were evacuated or not; and you had to classify all the houses in order to find out whether they had really left. You had to go over the whole city to see whether they had left or not, so that you were dealing with a larger population than 30,000.

23,904. What became of the people who had disappeared?—They had gone into the villages and the surrounding places at once.

23,905. At what stage of the epidemic was the great voluntary exodus, or flight, as it were?—I could not say it was, but I suppose it was about a month.

23,906. Before you came, or after?—It was still going on when I came; the bulk had gone out.

23,907. The bulk had gone out before you came?—Yes.

23,908. I suppose you did not know where they went to?—They went to the surrounding villages and fields, and they disappeared. They could not go out by train, for instance. Tickets were refused, without a special pass.

23,909. You do not know when the voluntary evacuation really commenced?—No, I could not say definitely; it had commenced before I came.

23,910. Why did the people run away?—I thought it was simply on account of the fear of segregation, and of going to the Plague Hospital, and also the disinfection of their houses, and that sort of thing. It was not so much the fear of the disease, I think, from what I have seen.

23,911. You think the exodus did not occur till after segregation had been put into operation?—The people knew all that took place in Bombay, and other cities. They knew that they would be segregated, and their houses disinfected, and that they would be put to all that trouble in that way. They knew, of course, what was going on.

23,912. Have you any knowledge as to whether by this flight, plague was imported into any of the neighbouring villages?—Yes, distinctly.

23,913. Cases did not come within your personal knowledge, but you know of them?—I have had nothing to do with the villages, but I have heard that that did take place.

23,914. How many people did you get into the health camps?—I did not know the population of the health camps at that time.

23,915. Have you any idea; was it 5,000, or 20,000?—There were three main camps, and it is rather difficult to say.

23,916. Were the evacuated people allowed to return to the town on any conditions?—The city was completely evacuated at the end of December, and in March, special well-known people were allowed to go back, people who had been known to have been living in the fields, or in the camp, healthy people.

23,917. Not before?—No, not till March 1898, I think.

23,918. In the meantime they were not allowed to go to the city at all?—They were not supposed to, of course.

23,919. They may have gone contrary to regulations?—Yes, they may have gone contrary to orders, but I do not know.

23,920. Not merely to follow their occupations during the day?—They were working at their occupations outside in the camp, the weavers, and others.

23,921. You managed to transfer the weaving and other apparatus?—Yes, we transferred it.

23,922. And all the ordinary handicrafts were carried on outside, in the camps?—Yes; I have seen them making wheels, and also blacksmiths working there.

23,923. After this evacuation, how did you disinfect the houses; what did you do?—They had special pumps to scatter disinfectants all through the houses, to wash the houses and sprinkle them thoroughly with disinfectants. All rags and dirty clothes were taken out. Anything of value was disinfected, but the other things were burnt.

23,924. You disinfected with chemical disinfectants?—Yes. Of course in the case of the lower houses, the poorer houses, the roofs were taken off; that is in single storey houses.

23,925. You let in light and air as far as you could?—Yes.

23,926. What did you do with regard to the better houses?—They were treated with chemicals, and after that they were limewashed. The better houses were only disinfected with chemicals.

23,927. Had they a sufficient number of ventilating apertures?—Yes; they were respectable houses with good windows, and so on.

23,928. Do you know whether this evacuation did any good, as far as the extinction of the plague among the evacuated was concerned?—Yes, I should think so, most distinctly.

23,929. On what grounds do you think so?—The moment the city was evacuated, plague disappeared.

23,930. In the camps?—It disappeared altogether, if you refer to the statistics.

23,931. I think you said the evacuation was completed in December?—Yes.

23,932. Could you tell us, generally, how many cases had occurred before this evacuation was completed?—The following list shows the weekly number of attacks and deaths in Sholapur City:—

Week ending			Cases.	Deaths.
1st October	1897		13	9
8th "	"		6	4
15th "	"		26	8
22nd "	"		50	45
29th "	"		116	90
5th November	"		146	117
12th "	"		143	118
19th "	"		221	182
26th "	"		363	297
3rd December	"		502	377
10th	"		501	436
17th	"		300	246
24th "	"		134	149
31st "	"		53	36
7th January	1898		26	27
14th "	"		9	9
21st "	"		7	11
28th "	"		5	8
4th February	"		1	2
11th "	"		—	7
18th "	"		1	4
25th "	"		5	3
4th March	"		—	2

23,933. The number of cases in the town, then, immediately became greatly reduced in a very striking way after the evacuation was completed at the end of December?—Yes, it was a very striking fact.

23,934. Do you know how many cases occurred in the segregation camp?—Yes, I can give you the number if you care to have them.

23,935. Can you give them, week by week, or every 10 days, as they occurred?—There were several segregation camps. The first segregation camp was formed in the fields round the Plague Hospital. There was a special Plague Hospital built. There were 1,421 contacts admitted into this camp. Out of that number there were 101 cases of people who developed plague. 1,320 people were discharged.

23,936. Can you give me the numbers in the evacuation camps?—These are the health camps. I could not tell the number of inhabitants in the health camps.

23,937. Can you tell me the number of cases that occurred among the people who were evacuated from the city?—No, I could not give you that.

23,938. Have you not got any statistics?—No.

23,939. Have you no means of finding out how many people got plague, under your own observation? Were they not reported?—Yes, they might be worked out.

23,940. Can you evolve that information from this table?—That is how the cases occurred. The dates of the plague cases and deaths that occurred among the evacuated population are as follows:—

Week ending	Cases.	Deaths.
7th January 1898	10	9
14th „ „	9	9
21st „ „	7	11
28th „ „	5	8
4th February „	1	2
11th „ „	0	7
18th „ „	1	4
25th „ „	4	2
4th March „	0	4
Totals	37	56

23,941. The impression is that the evacuation had very quickly reduced the number of cases?—In my opinion that is so.

23,942. The figures bear that out?—Yes; and, from what I saw, I should think that is so.

23,943. When you allowed the people to return to the town, did you have any recrudescence, as it were, of plague?—No, none whatever.

23,944. Has it remained free from plague since their return?—Yes, it has.

23,945. There have been no further cases up to the present?—There have been a few scattered imported cases through the town occasionally since.

23,946. By what means did you prevent these imported cases from starting a new epidemic? — The contacts of these cases were immediately segregated, and the house was treated in the former way. The house was evacuated, and re-disinfected, and left unoccupied for a certain time.

23,947. Everyone was removed from that house?—Yes; and then the house was disinfected, and left unoccupied for about a month or six weeks.

23,948. How would you explain the success with which you have now prevented an importation of plague into this large city, from lighting up an epidemic, as contrasted with the failure of your measures when the plague originally occurred? What is the difference in your methods now, and how do you explain why you have succeeded now when you did not succeed before?—The city is in a different condition to what it was then; it is very much cleaner, for instance.

23,949. Anything further?—Probably the very susceptible people have taken plague and died; and the cases have been immediately detected, and steps taken.

23,950. Is not that probably alone enough, that you are able to get sufficiently early information now, where you could not get it previously? Is not that the material point in your success now?—It might be half the point. I consider that it is principally because most of the susceptible persons have been removed.

23,951. And what are the other points?—The city is cleaner, and the people are not so susceptible; having gone through an epidemic, the susceptible people have been removed, and have had plague, and all that.

23,952. What is the chief provision in making segregation useful for preventing an epidemic when plague is imported into a town?—My opinion is that we must catch the first one or two cases.

23,953. Have you any knowledge as to rats having been instrumental in propagating plague?—No; I have not. On two occasions since the epidemic I have been asked to go and see dead rats. The people get very excited, of course, and I went and saw the rats. The first case I went down to see was that of a young rat and a mouse, lying together. That created a great scare, but I took it that cats had caught these two and killed them. However, the people were very excited. Since then I have seen two dead rats in a house, but there was nothing further. The house was disinfected, and so on.

23,954. There have been no great number of deaths among rats in this epidemic to your knowledge?—No; not to my knowledge.

23,955. How do you think the plague is extended from one person to another?—I think by contact—dirty infected clothes. That is all I have had experience of.

23,956. Have you had any instances of clothes having conveyed infection?—Yes.

23,957. Will you detail any of those instances?—I could not give a specific instance, but I know of several cases where clothes had been stolen from the Plague Hospital by temporary attendants, had been concealed, and cases occurred from those clothes. I thought they had occurred from those clothes.

23,958. The people who obtained these clothes suffered from plague?—Yes; they took plague.

23,959. What was the general characteristic of the houses in which most cases of plague occurred? Were they the best houses, or the worst?—Cases occurred amongst the better and the poorer classes equally, in my opinion.

23,960. In what kind of houses did the better classes live? Can you give any description of the kind of house?—They are very good houses of course. In comparison the houses in which the better class people live here are really very good houses, I should say.

23,961. And the poorer class houses?—They are generally four mud walls, with a roof of thatch, or sometimes tiles.

23,962. An equal number you think occurred among the rich and the poor?—Yes.

23,963. You have no experience of plague in the out-villages?—No: none at all.

23,964. (*Mr. Hewett.*) I understand you to mean that the possession of a good house did not secure a person against immunity from plague?—No.

23,965. The disease broke out first of all in the servants' quarters of the Europeans?—Yes.

23,966. It then went to the Sadr Bazar?—Yes.

23,967. How do the houses in the Sadr Bazar compare generally with the houses in the rest of the town?—There are also good houses there of course, but there are also dirty houses and huts.

23,968. Are they pretty good there, or are they below the average?—There are not so many rich people in the Sadr Bazar; they are mostly working people.

23,969. You say 1,500 cases were reported here in the five weeks ending December 31st. I suppose you cannot estimate what the number of the people in the town was during any one week of that period?—No, it would only be guess work.

23,970. But is it the case that after the end of November, the population of the town was rapidly diminishing?—Yes, distinctly so.

23,971. Do you think it is possible that the epidemic reached its height in the middle of December, and then went down of its own accord?—I do not know, I could not say that. I thought it was the evacuation that did it—the people coming out of the houses where the infection was.

23,972. When the 501 cases took place in the week ending 10th of December, was not a great portion of the town evacuated by that time?—Yes, I suppose about three-quarters of the houses had been inspected, and the people turned out.

23,973. When you examine a female corpse, do you examine the groin?—I do always.

23,974. There is no objection taken to your doing so?—No, not at all.

23,975. Can you tell us the number of imported cases that have taken place since the people have returned to their houses?—Ten. One in April 1898, one in June 1898, one in August 1898, one in September 1898, two in October 1898, three in November (two of them on the same day, and from the same place); and one in February 1899.

23,976. (*Mr. Cumine.*) You said I think that segregation of contacts is useful, if applied to the first two or three cases detected in a town?—Yes, I think so.

Mr. W. M. Muat, M.B.

6 March 1899.

23,977. Does the following passage in your précis of evidence still represent your views on the subject of segregation:—"Segregation to be of any avail must "ensure that the first two or three cases are detected: "after that the means defeats its own end in that the "inhabitants immediately take fright. Notwithstanding the means taken to prevent it, the inhabitants "of this city immediately fled to the surrounding "villages, carrying the infection with them. The small "number of plague cases occurring in the contacts "segregated, did not, I think, counter-balance this "evil."?—I am still of that opinion.

23,978. Did you notice that there was anything in the nature of the floors of a room that had any effect on the number of people attacked in that room? Were they stone floors, or wooden floors, or earthen floors, that were most liable to get infected with plague?—Most of the houses in the city have earth floors; a very great majority.

23,979. You did not notice that one kind of floor was more liable to give infection than another?—No. You see so many earth floors, that your attention would not be drawn to that.

23,980. (*The President.*) As you use both words, segregation and evacuation, might I ask you if you mean exactly the same by both words?—No.

23,981. Will you define what you mean by segregation?—By segregation I mean contacts being put in a special camp.

23,982. You mean the removal of the patients and the contacts only, not the surrounding inhabitants?—Yes.

23,983. By evacuation what do you mean?—General evacuation, the people leaving the city.

23,984. Of the whole city, or a large area?—Of a large area.

23,985. Therefore, while you think the segregation and the removal of the patients and of the contacts in the same house is useful, still you consider that it is only so where you have very early information of first cases?—Yes.

23,986. On the other hand, you think that evacuation is always useful?—Yes, always useful.

23,987. (*Mr. Hewett.*) Do I understand that you think that evacuation is useful to the place from which you remove the people? Do you think Sholapur town for instance would benefit by evacuation?—Yes.

23,988. But might not the places outside somewhat suffer from it?—It just depends on the way it is done, I take it.

23,989. You say that people ran away from the town carrying infection to the neighbouring villages. Do you think that the evacuation of the city led to that result?—It did, but that is not the compulsory evacuation by the authorities. That came about by the people running away themselves, in order to try and escape segregation.

23,990. In order to make the evacuation of a big town effective, is it not desirable that you should be able to get hold of all the people who leave the town, and keep them under observation?—Yes.

23,991. Is it possible?—No, not in a town of 63,000 inhabitants.

23,992. (*The President.*) In regard to this question of segregation, if you got early information of one or two imported cases, such as I understand you had originally, and if you segregate these people (the actual patients and the contacts) even although there were a panic, if they were the only cases, would there be any harm in other people running out of the town because of the panic?—No, I do not think so, if the people were apart from the commencement, and had no contact with the cases.

23,993. But I understood you to say that there would be no benefit unless you got information of imported cases and took away the patients and the contacts? You now get information of the imported cases, and are able to segregate them and the contacts?—We get all information up to now, I should say.

23,994. You do that without panic now?—Yes.

23,995. There has been no exodus?—Not because of these specific cases.

23,996. How do you account for that?—I suppose the people are not so much afraid now, and the measures are not so very irritating to them.

23,997. What measures?—Segregation and evacuation and disinfection.

23,998. Have you made any variation or change in the measures?—No.

23,999. The measures remain the same?—Yes.

24,000. But the people are not so frightened of them now?—No.

24,001. As they become accustomed to them, they learn what they mean?—Yes, they see the benefit of it to themselves.

24,002. (*Mr. Hewett.*) Supposing that you had an outbreak again in this town, do you think that the people would run away?—I do not think they would, unless it became very bad. If it did, I suppose they would.

24,003. They did not run away when the epidemic first broke out?—No, but when it started in the Sadr Bazar, the people in the main city took fright and ran away.

24,004. Have you noticed that the Mangs in this town have remained relatively free from plague?—Yes, I could take you to a little patch on the borders of the town which was not evacuated. There were very few cases, and the people lived there all the time.

24,005. Why were they permitted to live there?—Because they would have fled, and gone out, and struck work.

24,006. Were they not used to work within the town?—Yes.

24,007. That was the object of keeping them there?—Yes, that was the object of keeping them there.

24,008. Do you attribute their comparative immunity to the fact that they did not mix much socially with the other members of the town?—I am not prepared to answer the question. I mentioned the fact of the few cases that occurred in the unevacuated Mangawada, to show that plague cases were not more frequent amongst the poor and dirty classes than amongst the rich and better classes.

(Witness withdrew.)

Lieut. M. E. L. Bruce, I.S.C.

Lieut. M. E. L. Bruce, I.S.C., called and examined.

24,009. (*The President.*) I believe you are in the Staff Corps?—Yes.

24,010. And you have been on special work at Sholapur?—Yes.

24,011. Since what time?—15th November 1897.

24,012. (*Mr. Hewett.*) At that time how many villages were affected in the Sholapur district?—I was working in the city from the 15th of November to the 26th of December. That was the date it was turned out. There were about three villages which were known to be infected during that time.

24,013. You were employed in the city up to the end of December?—Up to the 26th December, and then the village inspection was done by me to find out how many villages were infected. I went out on 26th January. We then knew of only about three or four villages, but by the 4th of February we knew of 50.

24,014. I should like to ask you one question about the town first; can you give an estimate as to the number of persons there were in the town in the week ending 10th December, when there were 501 cases of indigenous plague?—I cannot give you the exact figures, but I should think there would be from 25,000 to 30,000 people in the town.

24,015. By the beginning of February you found 50 villages infected?—Yes.

24,016. Were you able to trace the infection in the case of many of these villages?—The infection could be traced in almost all with very little trouble. I found out that people had come from Sholapur and were living in the fields and some in houses.

24,017. Since February 1898, when there were 50 villages infected, what was the maximum number of villages you had infected at one time?—There were 50 villages infected at that time all round Sholapur, and there were three or four villages in the Madha taluka.

24,018. Have you had more than 50 villages infected at one time?—No.

24,019. At the present time how many villages are infected?—At the present time there are about seven villages infected, though they are not certain whether it has not stopped.

24,020. Otherwise you have no plague in the district?—In two villages we have got plague, I have got reports coming in every day.

24,021. You have two villages with plague and seven which are suspected?—Seven are under inspection.

24,022. During the time when plague was at its worst what was the maximum number of European officers employed in the villages?—There were three European officers.

24,023. I suppose some of these villages are at considerable distances from one another?—The place was divided into wards. The furthermost villages are about 15 or 17 miles from here.

24,024. During that time what was the maximum number of villages under your personal control?—Fifty villages and ten infected villages, I think.

24,025. Did you find it possible to visit each of these villages once a day?—No.

24,026. How often could you visit them?—I did not go in for visiting villages a great number of times. I camped at one village, and did the whole of the work in that village, and stopped plague in it if possible at once, and then went on to the next.

24,027. The people remained in the fields after the village had been evacuated?—Yes, the people remained in the fields.

24,028. And you stayed there until plague was practically got under?—No; I did the work necessary to stop plague in the course of two or three days; I then went on to another village and worked at that for two or three days.

24,029. You did not stay in these villages to see if the people obeyed instructions with regard to their not going back to their houses?—No.

24,030. Do you think that more European officers than were employed in Sholapur are required to carry out work in the villages effectively?—Yes, most distinctly more were required. I was entirely alone in the work. I had a Plague Officer under me, and I had a certain number of sepoys who helped me.

24,031. Were you employed in the villages during the monsoon?—I was out all through the rains, from July to the present time, practically.

24,032. Do you think that making the people evacuate a village site during the rains causes hardship, or not?—I think it causes them a certain amount of discomfort, but it is quite worth it. The people do not object to it, to anything like the extent one would suppose.

24,033. You think that during the rains in the black cotton soil and in the exposure to which they are subjected, the people are not made more liable to other disease by being evacuated at that time?—I noticed absolutely no amount of higher mortality from other diseases. The people were wonderfully well considering everything.

24,034. When you have got the people segregated in their own fields, and a case of plague occurs among them, what measures do you take?—I make them commence in the early morning, and pull down the original hut in which the case occurs. Next I make them put up a small hut for the sick man, a three-cornered hut so that nobody else can get into it. I send them off to have their clothes washed, and late in the evening when they have done that they build a new hut for themselves. I make them keep out as many things as possible, only allowing them to take in their cooking materials and the clothes they actually require.

24,035. Who does that if you do not happen to be in the particular village in which the case has occurred?—The village officers have instructions in writing and they are told to carry them out. As a rule I think they do the work fairly well.

24,036. Do you use any disinfectants in the villages now?—No.

24,037. Why not?—Because as far as the houses are concerned we have several cases of villages which have shown that it does not appear to be necessary; they have been re-occupied without any further recrudescence. With regard to clothes and other things, washing and sunning them have proved quite sufficient.

24,038. In the case of these villages which have been re-occupied without disinfection, how long did you keep the people out?—In some cases over three months.

24,039. What was the minimum time for which you kept them out?—Three months.

24,040. You think that after people have been kept out of a village site for three months, it is practically safe to let them back again without taking any measures to disinfect beyond improving ventilation and allowing sunlight to enter?—Ventilation and emptying the houses.

24,041. Do you think that plague is taken from village to village mainly by human agency or any other way?—Mainly by human agency.

24,042. How do you think it is carried about in a village?—By rats.

24,043. Have you noticed any instance in which rats brought plague from one village to another?—No.

24,044. In your experience what is the course of infection in a village?—First of all a case occurs in one house, and then I have always thought that rats take it to other houses. Of course, people communicate it themselves.

24,045. Do you think that the importation of the disease from outside is in the majority of cases followed by mortality among rats before the residents of the place get infected?—I think it is.

24,046. Have you any instances of villages in which there has been no mortality among rats?—No. It may have occurred, but I do not know of it. It has not been observed.

24,047. Have you had any village in which no mortality has been reported to you amongst rats?—No.

24,048. That is to say you have had rats dying in every village?—Yes.

24,049. Have you noticed that any other animals are subject to plague?—No.

24,050. Have you had any instance in which plague has been imported from one village to another simply by means of clothing without any person having come from an infected to an uninfected area?—No, I have no experience of that.

24,051. Have you noticed that the Mahars and other outcast people have escaped infection when a village has been infected?—Very frequently, even though not evacuated.

24,052. In how many villages have you noticed this?—In four or five, I should think.

24,053. Would you infer from that that the reason for their escape is that they do not mix with other people?—That, and the fact that they do not keep corn in their houses which might attract vermin.

24,054. (*The President.*) What sort of lives do these Mahars lead?—They are always working. They are practically village servants. Of course, they are very poor. Some of them in the big villages own a certain amount, but as a rule they own nothing. They are fed by the village.

24,055. Their life is a very out-of-door one, is it?—Yes, very.

24,056. More so than the other members of the community?—Much more.

24,057. That is the great characteristic?—Yes.

24,058. Have you got any example of an evacuated village in the rainy season where the people seemed to be not much discomforted by being out?—Three villages were out through very rainy weather. I was out with them all through the time, visiting them, and going round to see what their complaints were. Of course, they were put to some discomfort undoubtedly, but they managed all right, and their complaints were

Lieut. M. E. L. Bruce, I.S.C.

6 March 1899.

very few. They certainly preferred to be out to living in the village.

24,059. How did they show their preference?—I had one case where they tried to raise an objection, I offered to let them go back to the village, but they refused.

24,060. Have you any examples of the speedy termination of an epidemic in a village by the complete evacuation of that village?—Yes.

24,061. Could you give us a few examples briefly?—Plague commenced in Korali village in the Sholapur taluka about the 21st of March last, and I got news of it on the 27th. Six families were infected then. The village was vacated on the 29th of March, and plague ceased on the 2nd of April. In all nine families were infected.

24,062. Can you distinguish between before and after?—Yes. There was only six families attacked on the 27th. Between that and the 2nd of April three more families were attacked.

24,063. What is the normal population of this village?—About 800.

24,064. Have you other examples of a similar description?—Nothing so good. Patri village was a rather worse example, because plague only showed itself in the form of buboes in one family; we had about four cases of fever immediately afterwards, and about two deaths, and then it stopped. I do not think it is a sufficiently good case.

24,065. Do you know which of the villages evacuated had the largest population?—Mole village, with about 4,500 inhabitants.

24,066. Is that the maximum?—Yes.

24,067. Do you think it is quite convenient to evacuate a village of that size?—No, I think it caused plague to spread to about 10 other villages.

24,068. Because of what?—Because the people simply ran away, and there was nothing to stop them.

24,069. You had no cordon?—No.

24,070. You could not well manage so large a village?—I could not manage it at all; it was quite impossible. I was by myself.

24,071. (*Mr. Hewett.*) When you say you could not manage it yourself, I suppose you mean that the people were determined not to stay in the fields?—The people had lands in other villages. Naturally there was a great number of well-to-do people in such a large population, and they simply went off to other villages. If the other villages could have been depended upon to keep them out, it would have been all right; also, had we been able to make examples of them. In any case it is very difficult.

24,072. Would you draw a distinction between the smaller and the larger villages? In the smaller villages you mainly had agriculturists who are tied down to the village, and do not want to run away to other places?—Yes.

24,073. And, consequently, with a small agricultural community you would find it much easier to take the people out of the village site and keep them in the fields?—Much easier; they would be more inclined to obey in any case.

24,074. But your difficulties are increased when you meet with a population that is accustomed to travelling and has interests outside the village site?—Exactly.

(Witness withdrew.)

(Adjourned till Tuesday, 7th March, at Ahmednagar.)

At The City Magistrate's Office, Ahmednagar.

SIXTY-SECOND DAY.

Tuesday, 7th March, 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. C. Hudson, I.C.S.

7 March 1899.

Mr. C. HUDSON, I.C.S., called and examined.

24,075. (*The President.*) You are the Collector here?—Yes.

24,076. And you have had considerable plague experience in Ahmednagar?—Yes.

24,077. (*Mr. Cumine.*) When did you come to Ahmednagar?—In the end of December, 1897, practically the 1st of January, 1898.

24,078. When did the plague begin in the Ahmednagar district?—I cannot tell you that off-hand, but about the end of October.

24,079. What was the first place affected, do you remember?—I do not know that. Captain Walton will be able to tell you that.

24,080. Before you came to Ahmednagar had you had experience of plague in any other district?—Yes; in the Thana district, Salsette taluka.

24,081. For how long?—From February, 1897, to December, 1897.

24,082. Have you noticed whether infection amongst rats always intervenes between the infecting imported case, and the first local case?—No; I have not always noticed that.

24,083. Do you know of any instance where clothes have certainly carried infection?—Yes; I know an instance in this district, in Rajapur.

24,084. Can you, with certainty, exclude the possibility of human agency, the possibility that the person who brought, or went to fetch the clothes, was the agency that communicated the infection, and not the clothes?—In this case it was a Marwari family attacked, and the infection was given to the Mahars. There was no plague in the Maharwada. The Mahars got the plague, and I think it is almost certain that it was conveyed in that way.

24,085. It is certain that the Mahars got the clothes?—Yes; that is quite certain.

24,086. Is it certain that the clothes were from an infected person?—Yes.

24,087. Could you describe the circumstances to us?—No; I cannot say any more than that.

24,088. Is the case within your own knowledge, or has it been reported to you?—It has been reported fully from this district, in an official report to Government.

24,089. How is it, that, in your opinion, plague is carried from village to village, by what agency—human

agency or rats, or what?—I think nearly always by human agency. In one case they said rats had done it, but it was only a little bit of village gossip, I think.

24,090. How do you think it is carried from house to house within the limits of a village?—I do not know. It does certainly seem to go from house to house, but in this city of Ahmednagar there were no deaths of rats observed like there were observed in Bandra. In Bandra I should say rats certainly did carry it about.

24,091. Did you see any rats going from one house to another?—No. (Note by witness on correcting proof of his evidence:—Since giving my evidence I have had two opportunities of observing the spread of infection; in the Maharwada of the city, and in a village called Sonevadi; in neither case could it be said to have spread from house to house as at Chichondi, where no dead rats were observed.)

24,092. Have you any experience of the kiln system of disinfection?—No; I should think it would be a very dangerous system to adopt generally, judging by experience in Savedi here, where there were three workmen engaged in digging up the floor of a room, and two of them got plague. Of course no precautions were observed, but still they got it.

24,093. Have you any instances where animals, other than rats, such as cats, pigs, and squirrels, certainly died of plague?—No.

24,094. Is there any instance within your knowledge where plague has recrudesced, that is to say, where a village which was infected has had a long interval of freedom, and plague has appeared in it again without a re-importation of infection from without?—No.

24,095. Have you any instance where a village has become infected this year, which was not infected last year, but which is next to a village that was infected last year?—Yes; in the town of Bassein itself, in the Thana district.

24,096. What happened there?—The plague began there in December, and it was supposed to have been stamped out in June.

24,097. I was asking you about a case where plague has appeared in a village this year which was not affected last year, but which was next to a village that was affected last year?—In the case of Savedi, Varanghusi, Chichondi Patel, and a village in the Khandesh district recently at Kanaswadi.

24,098. This last is not within your knowledge?—No.

24,099. What happened in those cases which are within your knowledge?—Savedi is next door to the city of Ahmednagar, and there was no plague there last year, and it broke out this year.

24,100. How long was the interval between the ceasing of plague in the Ahmednagar City and the appearance of it in Savedi?—About six months.

24,101. Have you noticed whether there was any heavy infant mortality in Savedi during those six months?—No, I have not noticed it. I do not think there was.

24,102. What is the next instance?—In Varanghusi a similar thing occurred. Pendshet, a small neighbouring village in the Ghauts, was infected last year, and, about six months after, Varanghusi became infected.

24,103. Have you been unable to trace any infection of Varanghusi this year from without?—When I wrote my précis of evidence it was suspected that it may have been imported from a village in the Thana District, and it is possible it was so imported. I am inclined to think myself it was so imported.

24,104. The third case?—In Chichondi Patel, 13 miles from here. There was plague in a village called Athvad previously, and Chichondi Patel got infected this year, and the source has not been traced.

24,105. About Chichondi Patel have careful inquiries been made to find out whether it did not come into it this year from without?—Yes, very careful inquiries have been made. I myself and others inquired on the spot, and we could only find out that the Chamars first got infected, but whether they were infected by Marwaris or not has not been found out; it is only known that the Chamar families first got plague.

24,106. Had any of them been away, or had any outsider come to them?—That has not been found out.

24,107. Have you examined the death-rate during the interval of six months to see whether it was suspicious?—Yes.

24,108. Was it suspicious?—No. That is how the 20th of October was fixed as the probable date of the outbreak; by examining the births and deaths register.

24,109. Then the outbreak had been going on for some time this year in Chichondi Patel before it was discovered?—Yes, from about the 20th of October till about the 30th of November or the 1st of December.

24,110. Have you noticed whether cases that come direct from Bombay into this district readily infect this district, or whether the cases that most readily infect this district are cases that have come from some half-way house, such as Lanauli?—No, I have not noticed that.

24,111. Is there any other interesting fact that you wish to tell us about?—Yes, with regard to inoculation.

24,112. What have you to say about that?—I remember reading Professor Gajjar's evidence, and he seemed to think that inoculation was prejudicial to the uninoculated; that it made them get plague in some way or other. My experience is quite opposed to that, because about half the camp was inoculated and half not, and nobody suffered in any way; none of the uninoculated got plague, or anything like that, from the inoculated.

24,113. At that time there was no plague in the camp?—I was camped near infected villages, but there was no plague actually in the camp.

24,114. (*The President.*) Have you encountered any cases in which plague has occurred among the inoculated?—Yes, I know of two cases, but I have not seen them.

24,115. Can you tell me if the type with regard to the virulence of plague has varied at any times of the epidemic?—No, I do not think so.

24,116. It has been the same throughout?—Yes.

24,117. Have there been any cases which have been so mild that the diagnosis was difficult?—Not that I personally know of. I know of mild cases escaping from camps, and getting let through without being discovered to be plague cases at all. I know of one instance of that kind where infection was carried by a mild case of that description.

24,118. The symptoms were so slightly pronounced that it was not recognised as a plague case?—Yes.

24,119. By whom would that recognition be made?—By a Hospital Assistant.

24,120. Have you had much experience of disinfection?—Yes.

24,121. What is your opinion as to the value of disinfection?—I think it is a very good thing for the workpeople who are engaged on the work.

24,122. Who are putting the houses in order, or what?—In the Deccan districts, where they have to open up mud roofs.

24,123. Do you mean that the houses should be disinfected before the workmen go in to do that?—Yes.

24,124. Do you include in that exposure to light and air, or merely chemical disinfection?—I think it would do, if the workmen had disinfectants to wash themselves with.

24,125. I am speaking rather of the habitations?—I am referring to the safety of it for opening up, simply. I think opening up the houses is the best thing of all.

24,126. You put that kind of disinfection first because it comes to be a disinfection before disinfection by chemical agencies. Is that the result of your experience?—Yes, but I could not give any explicit reasons.

24,127. That is the impression which is produced in your mind?—Yes.

24,128. How long do you consider, before a house became safe, that this non-chemical method of disinfection should be in operation in that house? Would it be a matter of a few days or weeks?—I think it would be weeks.

(Witness withdrew.)

Capt. W. C. Walton, I.S.C.

7 March 1899.

Captain W. C. WALTON, I.S.C., called and examined.

24,129. (*The President.*) You are in the Indian Staff Corps?—Yes.

24,130. What is your official position with regard to plague?—I am Magistrate of the Cantonment, and I am in charge of all plague operations in the cantonment.

24,131. (*Mr. Hewett.*) The cantonment was the first part affected here, was it not?—I have been looking back in the old correspondence, and I find there was a case in Bhimgar on the 9th of March 1897, which is a village joining on to the Sadr Bazar.

24,132. Was that an isolated case?—Yes, and apparently imported.

24,133. Do you know where the patient came from?—It was brought by a Mali from Poona. His wife had died there of the disease.

24,134. Did any people get the infection from this man?—I do not know where they got the infection.

24,135. At that time did you hear of any more plague cases?—No, at least I cannot trace any. I did not come here till December. On looking up the correspondence, I find that there was a case.

24,136. When was the first case in the cantonment? On the 27th of September, 1897.

24,137. Was this man a private servant?—He was a bullock driver of the Roman Catholic Chaplain.

24,138. Had he any connexion with Bhimgar?—He went out to buy grass for the bullock. It was a rainy day, and he got wet, and whether he went to Bhimgar, or whether he went among the gawlis in the Sadr Bazar, is not known.

24,139. Did any other servants of the master of this man get plague?—Four of them died in hospital with plague, the bullock driver, the cook, the daughter of the cook, and also the cook's son.

24,140. Who were the next people affected after these servants?—The gawlis were the next.

24,141. Was there much intercourse between the gawlis and the Kunbi who was first affected?—He might have gone to buy grass from the gawlis. Of course they keep cows, and that is the only way I can connect them.

24,142. Would it be likely that there would be social communication between them?—Yes.

24,143. I understand that the outbreak among the gawlis took place on the 3rd of October, 1897?—Yes, that is the first case heard of.

24,144. And after that you had a search of the Sadr Bazar on the 8th of October?—Yes, a search was made.

24,145. What orders were then given to the residents of the Sadr Bazar?—They were ordered to vacate their houses within 24 hours and take up their residence in a camp.

24,146. What was the population of the Sadr Bazar?—About 3,000.

24,147. And how many of them took up their residence in the camp within 24 hours?—1,600.

24,148. What happened to the remaining 1,400?—They scattered all over the country, and I do not know what happened to them.

24,149. Then after the people occupied the camp, did many cases of plague occur among them?—A good many cases, yes. In a short time it went up to 66 cases.

24,150. Up to Christmas were how many there?—There were 75 cases. By the 28th of November there had been 66 cases and 49 deaths, and the people and their clothes were then all disinfected.

24,151. By Christmas 1897 there had been nine more cases?—Yes.

24,152. How do you account for the occurrence of cases in the camp?—I do not account for it, but the Principal Medical Officer of the Poona district came here, and he accounted for it by the fact that the clothes had not been disinfected.

24,153. You mean before the 28th of November?—Yes.

24,154. But after the disinfection on the 28th of November, there were other cases?—There were a few dropping cases.

24,155. How do you account for the cases having occurred?—I cannot account for them all. I know one particular case I accounted for was that of a man who had strict orders that he was not to go to the city which was infected at that time, and he went to the city, and slept there.

24,156. Do you think that other inmates of the camp were doing the same thing?—Very few; we had policemen on the roads.

24,157. Did you have any cases of plague in the camp after Christmas day, 1897?—No, that is the last case in the camp. There were other cases in the cantonment.

24,158. In other parts of the cantonment?—Yes.

24,159. In what parts of the cantonment were there cases after Christmas, 1897?—There were cases in the Kotla, in the Regimental Bazar, and, I think, amongst the Native troops.

24,160. Were the cases very numerous there?—The Kotla is a walled enclosure inhabited by Muhammadans, and I got information one morning that there was a case of plague there. I rode down, and found two dead bodies, and everybody cleared out; and about four or five of them died in the surrounding country to my knowledge. They were found by various Mamlatdars, and brought in.

24,161. These people who left the Kotla were under no supervision after they left?—They cleared out before we knew anything about it.

24,162. Were there cases in any other parts of the cantonment?—There was one case in the syces' lines of the Royal Artillery.

24,163. Only one case?—Yes.

24,164. Did you find it necessary to evacuate any other portion of the cantonment?—The Regimental Bazar was evacuated, but they did not run away; we caught them all.

24,165. How many cases were there before and after evacuation respectively?—On the 9th December a case occurred in the Regimental Bazar, in the Native Infantry.

24,166. How many cases occurred in the Regimental Bazar before and after evacuation respectively?—Only one.

24,167. That case occurred on the 9th of December; when did you evacuate the place?—The same day.

24,168. And you had no further case?—No.

24,169. When you evacuated the Sadr Bazar, and the other places that were evacuated, did you do anything to the houses?—They were unroofed and washed with perchloride of mercury and afterwards whitewashed.

24,170. After what date was that?—It was commenced as soon as the Sadr Bazar was vacated, on the 8th of October.

24,171. Did you have any cases among the people who went back to whitewash or cleanse their houses?—All the work was done by a gang of coolies. The people did not do their own houses. The whitewashing was done whilst the roofs were off; that was all done by a gang of coolies. I have not any certain information about it, but I believe one or two coolies at first took plague.

24,172. Was disinfection by means of perchloride of mercury carried out in every house of the Sadr Bazar, the Regimental Bazar, and the Kotla?—I cannot answer for the Sadr Bazar. I think they were all done. All the infected houses were done, but not the uninfected houses.

24,173. Did you do any uninfected houses in the Regimental Bazar?—One on each side of the infected houses.

24,174. Did you unroof only the infected houses or all the houses?—In the Sadr Bazar they were all unroofed, and the houses in the syces' lines and the Artillery were all unroofed, but I did not unroof all the houses in the Regimental Bazar.

24,175. When did you permit the people to go back to re-roof their houses?—On the 25th of January orders were issued that they might go in by day for re-roofing purposes.

24,176. When did you permit them to re-occupy the bazar?—On the 19th of March, 1898.

24,177. When were they permitted to re-occupy the Regimental Bazar?—At the same time, I think.

24,178. And the Kotla?—Yes, all of them.

24,179. Since they were permitted to re-occupy these places, have there been any cases of plague in the cantonment?—There have been two cases this year.

24,180. Where did they occur?—One was rather a strange case in the Royal Artillery syces' lines of a woman who had just borne a child, and she was taken off to the hospital. They said she had plague, and she died.

24,181. When was that?—Three months ago.

24,182. Had she come from outside?—As far as I could understand there was no reason why she should have plague.

24,183. The second case?—The second case was in a paddock in the Remount Depôt.

24,184. Did the patient come from outside?—It is rather a long story. A boy aged about 15 years died in this paddock. About six men with their families were looking after the horses in the open paddock, and they were living in six bamboo huts absolutely segregated, so to speak. The boy died there, and the Hospital Assistant saw him and said he had no signs of plague—that he died of relapsing fever. No particular precautions were therefore taken. A fortnight afterwards a baby died in these same six huts, and the Hospital Assistant again said there were no signs of plague whatever; the baby had died of ordinary fever. Then a third baby died three days afterwards, so I went down to see what they were dying from. The men themselves said they were located on an old graveyard, which was very unhealthy. I burnt down all those bamboo huts and sent them into another paddock. The mother of the baby had fever, and she recovered next day, and that made me think there was no plague. About three days after that another baby got fever, and then I sent them all to segregation camp, and disinfected their clothes. The baby died in camp. They were practically segregated in the second paddock which I sent them to, but I did not disinfect their clothes. After sending them to the segregation camp, I disinfected all their clothes. They have been out now about a week, and they have not had any fever.

24,185. Who decided that any one of these cases was a case of plague?—The Hospital Assistant who saw the baby that died said there were no buboes and no signs of plague, and the senior Medical Officer, Colonel Lane, saw the baby, and told me that it had buboes, and that it was plague: that is the last baby that died.

24,186. Did he make a report to you that this was plague?—After it died he did; it died in the segregation camp.

24,187. Who decided that the case of the woman who died in the Royal Artillery syces' lines was a case of plague?—The Civil Surgeon, Major Willis.

24,188. You were not able in that case either to trace any communication from outside by friends or relations of the woman, or to ascertain whether it was brought by clothes or anything of that sort?—The people had a right to go to the city or to any other villages. The woman was just going to bear a child, and it is not likely that she had been travelling about the country.

24,189. Was there plague in the city at that time?—There were a few dropping cases.

24,190. Has the death-rate in the cantonment during the year 1898 been above the normal?—No, much below.

24,191. Have you carried out any subsidiary measures for the improvement of the sanitation of the cantonment?—Yes. While they were out in camp I went and took up all the private latrines, and destroyed them, and disinfected them with perchloride of mercury, and then when they came back they were not allowed to have any private latrines, except very special ones. Also, in rebuilding their houses, they had to build on a particular pattern, allowing for lots of ventilation, big doors, and a good height to the roofs, &c.

24,192. You also condemned a certain number of houses?—Yes, we condemned some, and made one or two new roads right through them in some places.

24,193. (*The President.*) The result of your evacuation was successful on the whole, was it not?—Very successful directly the clothes were disinfected, but not before; the same as with the case in the Remount Depôt paddock.

24,194. What do you think is the essential requirement in order to obtain success in evacuation?—I think the great thing is not to allow the ground to be soiled by people evacuating all over the ground like they do in these places. You see people making a latrine of the road in most of these Indian cities. I think it is a very important thing that that should be stopped, and it can be stopped, I know.

24,195. In the evacuated camp, you mean?—No, in the bazars.

24,196. I am talking about evacuation. For instance, on removing people into camp, I thought you said that was successful in your experience?—It was successful after their clothes had been disinfected.

24,197. And in order to obtain the highest success by evacuation, what are the chief requirements to stop the epidemic? Under what circumstances would you be most likely to succeed in stopping the epidemic when you have adopted evacuation?—If you disinfect the people's clothes, and always make them sleep in camp.

24,198. The evacuation must be complete, and they should be segregated?—Yes, allowing them to go to business by day.

24,199. Is evacuation more likely to be successful if it is carried out just after the epidemic has commenced, or in the later stages of it?—It should be carried out at once.

24,200. Therefore, one of the greatest requirements for ensuring success is what?—Evacuation at once.

24,201. That I should think would imply early information?—Yes.

24,202. After you have disinfected, cleaned, and ventilated, have you found that the people who returned did not again acquire plague?—No, they did not.

24,203. You spoke of the structural changes which you have made; did these include windows where they were required?—Yes, two windows in each room, and a ventilator in the roof.

24,204. In what spirit have the people taken these changes?—Very well indeed.

24,205. Do you think they appreciate any advantages from these changes?—I do. They block their windows when they can, but I always unblock them. They like the ventilators. I always say to them, "You "were more healthy in camp than you were anywhere "else, and if you block up your windows, you will be "put into camp again, and you will get more air "there." They get more air in camp than they do in their houses.

24,206. But do they quite appreciate the advantages of the alterations?—They prefer a stuffy house, I think, but they do not grumble about it.

24,207. Do you think you could teach them the advantages of not blocking up their windows?—I am sure of it; they all see that they are more healthy here.

24,208. You said they blocked their windows, but when you tell them not to do it, do they still persist in it?—There is no doubt they do; they have to be opened up every morning.

24,209. By others than the inhabitants?—Yes, but they do not take it in a bad spirit at all. I think they appreciate the advantage of it, although they do not appreciate the comfort of it.

24,210. In regard to the whitewashing, I think you said that some coolies became affected when they were whitewashing?—When they were unroofing.

24,211. Previously to this unroofing, had any disinfection been carried out in these houses?—I cannot tell I was not here then. Every time when I have unroofed a house I have always disinfected first, and I have never had coolies affected then.

24,212. Those were cases which came under your observation, in which the unroofing was preceded by chemical disinfection, and in those cases there was no plague among the workmen?—Never. I have had coolies lifting plague patients in their arms, and showing the greatest pluck, and I have never had any plague amongst them.

(Witness withdrew.)

Khan Sahib B. S. Cardmaster.

7 March 1899.

KHAN SAHIB BYRAMJI SORABJI CARDMASTER called and examined.

24,213. (*The President.*) I believe you are Chairman of the Ahmednagar Municipality, and member of the Ahmednagar City Plague Committee?—Yes.

24,214. Has your plague experience extended throughout the whole time of the several epidemics?—Yes.

24,215. In what years had you plague in Ahmednagar?—We had some imported cases in 1896. Then we had also imported and indigenous cases in 1897 and 1898.

24,216. With regard to 1896, was there any epidemic following the importation?—No.

24,217. How do you think you escaped the epidemic at that time?—We had precautions at the railway station. We only had imported cases. There was no centre of plague in the surroundings. As soon as we detected any arrivals from Bombay or Poona, or from an infected place, we kept an eye upon them and had them inspected, and if we found anything wrong we drafted them to the hospital. There was another reason. That year was perhaps the driest year in Ahmednagar. There was a famine and scarcity of water. There was no centre of plague in the vicinity.

24,218. One of the points you have stated in your précis is that each imported case was kept under observation?—Yes.

24,219. So that you obtained immediate information?—As soon as an arrival from Bombay or Poona came into the station we registered his name, and a report was sent to the Municipality. As soon as we received the report we kept an eye over that man and watched him.

24,220. What did you do with him if plague occurred?—If he showed symptoms he was at once taken to the Plague Hospital and treated there, and the contacts and the family were also segregated.

24,221. And the house?—The house was disinfected.

24,222. In what way?—In 1896 perchloride of mercury disinfection was not prevalent. The house was whitewashed, and certain parts of the roof were cut open. The floor was also whitewashed—the outside and inside of the house and floors were whitewashed.

24,223. You did not employ any powerful chemical disinfectant?—No, not in 1896.

24,224. On the other hand you did open the roof?—Yes.

24,225. Could you tell me how many imported cases you had in this way to deal with in 1896?—There were 26 cases.

24,226. What was the population of Ahmednagar at that time?—36,000—perhaps more at that time—about 38,000.

24,227. In 1897 what was the history of the importation of plague?—So far as I have gathered, I think the importation came from the cantonment. In the last week in September we heard of cases occurring in the cantonment. We heard that a certain reverend gentleman had come from Bombay, and that one of his servants was attacked with plague. At that time the cantonment authorities had no separate hospital of their own, so that the patient was brought to Sidhibagh Hospital. For a month or so there was nothing in the city, but in the last week of October there was one case of plague—a Muhammadan, who had been to the cantonment. He was a native of Ahmednagar, but he had been going to the Sadr Bazar in the cantonment.

24,228. He took plague?—Yes, he had plague in the city. He was found in the city. As it proceeded we found that a great many people had escaped from the cantonment, and had sheltered in the city limits. We inquired into the history of the case, and it was established that the people had plague from the cantonment limits. The locality first affected was the nearest to the cantonment limits with only a wall intervening. There is a big open space, and most of the people who had dealings with the cantonment people lived in that locality, where plague was traced in Ahmednagar at the beginning.

24,229. I understand you did not get very early information of these cases—not so early as in the instance of the imported cases from the railway station?—No. In 1897 we had what we call the death-certificates system here. As soon as there was any death from any cause whatever a Hospital Assistant went there and certified the cause of death. The body was then taken out to the ghats for burial or cremation, so that there was no possibility of escaping or concealment. If there was a death, the death would be at once reported, and the cause of it. I should think that the first case detected so was very probably the first case of plague.

24,230. You got the first case by the death register?—Yes.

24,231. But these cases may have remained living and affected with plague in their houses for a considerable number of days before you found them out?—That was so with one Muhammadan family, and also with one barber's son. The boy was ill for about five or six days, but we only learned of plague there after the death of the boy.

24,232. During these five or six days is it possible that he may have disseminated plague by persons seeing him, or otherwise?—We made inquiries about it. Perhaps it was possible that the plague could be disseminated, because in the neighbourhood of it—the very next house—there was plague.

24,233. Subsequently?—Yes.

24,234. What was the further history of the 1897 epidemic?—We actually found plague travelling in a line always from house to house and from ward to ward. When we found plague broke out in ward No. 5, where the barber's son was, we found it was actually disseminating itself. We found numbers of cases there. We evacuated that ward first by blocks and then the ward. As we went on evacuating, the parts evacuated remained safe, and plague was actually found in those parts which were not evacuated.

24,235. In the contiguous part?—Yes.

24,236. And so it extended?—Yes.

24,237. What was the date of the first infection of 1897?—29th October.

24,238. Can you tell us what was the total number of cases of plague in that epidemic?—There were in all 407 cases.

24,239. What was the mortality?—Out of that number 92 recovered and 315 died—the period ranging from the 29th October 1897 to March 21st, 1898.

24,240. By the 21st March had the plague subsided?—Yes, it had.

24,241. In 1896 was there any special mortality among rats?—No.

24,242. In 1897 was there any special mortality?—No.

24,243. Will you describe the measures you adopted in the 1897 epidemic: you have already gone so far as to say that you evacuated?—Yes. When we found a house infected the first step taken was to carry the contacts to the hospital and the neighbouring people to the segregation camp. They were kept there for 10 days. If there was a second case in the same family 10 days were counted from the second date upon which the last case occurred. Soon after the patients and the contacts were removed, the house was disinfected with perchloride of mercury and the roof opened up. As a rule, we cut a hole three feet by two feet in the roof. If there were windows in the wall they were opened up, and the house was left open for a month or so, and nobody was allowed to enter it.

24,244. That refers to a house in which a plague case occurred?—Yes.

24,245. You also spoke of the neighbouring houses being emptied: what did you do with those houses?—In the beginning we started blocks—that is, a certain number of houses was taken on each side. The Civil Surgeon was generally present, and he would decide that certain houses on each side should be vacated and disinfected. The neighbouring houses were also disinfected, and opened up as long as plague had not assumed an epidemical form. But once the plague had assumed the epidemical form, then the people were asked to leave in numbers, in lots, and the houses were all opened up and the windows were opened. All the houses were, so to say, disinfected and whitewashed.

24,246. You adopted the same treatment as you would when disinfecting a plague house?—Yes.

Khan Sahib B. S. Cardmaster.

7 March 1899

24,247. You found that your first measure did not succeed in checking the progress of the plague to neighbouring houses, or to other parts of the town, did you not?—Yes, because when we found cases were occurring, although the neighbouring houses were evacuated, we thought that the block system would not do, and therefore we went to the ward system of evacuation.

24,248. Very small evacuation was insufficient; therefore, you tried a larger evacuation?—Yes.

24,249. What was the success attained by the larger evacuation?—As soon as a ward was evacuated, we found the mortality in that particular ward subsiding at once.

24,250. You mean among the people who were in camp?—They were asked to go and live in the fields. The Municipality did not give them any encampment. The open fields were the place where the people used to go to.

24,251. What is the history of the epidemic in the fields?—We have not sufficient data as to the field mortality. Still, from the reports I received, I found that the mortality was comparatively very little.

24,252. Trifling relatively to the condition of the city?—Yes.

24,253. To what extent had you to proceed in evacuating by wards?—We went on evacuating, ward by ward. We first evacuated Ward No. 5, then No. 4, and then No. 3. We evacuated Ward No. 8 last. I found until the last ward was evacuated, plague was appearing in those very places where people were actually found. We went on evacuating ward by ward. A certain number of people were allowed to stay in these wards who were disabled and blind, and could not go out. However, as we went on evacuating, we thought that we would keep the other parts safe—those parts which were not evacuated, and which had not got plague at the time when plague broke out in the wards here which were evacuated. Although we took special care to see the people who were asked to leave one ward did not go to other wards, still plague was found in those very wards which were not evacuated and which had not plague in the beginning.

24,254. Indeed, the evacuation even on the more extensive scale of ward evacuation was not sufficient to prevent the plague extending throughout the city to parts not evacuated?—That is so.

24,255. Did you evacuate the whole city?—Yes, we evacuated the whole city in the middle of March. We had to keep a certain number, who were blind and too ill to be removed, but they represented a very small number.

24,256. Did you follow out the same treatment in the evacuated houses as you have already described?—Yes.

24,257. What was the history of the epidemic among the evacuated after the entire evacuation had been effected?—Among the evacuated, those who had gone out to fields, the mortality was comparatively very small, and the general health was good.

24,258. At what season of the year was it—the dry season?—Ward No. 5 was evacuated in January, and by the middle of March, the whole of the city was completely evacuated.

24,259. You were still in the dry season?—Yes. We allowed the people to enter in the middle of April.

24,260. They commenced to return then?—Yes. The wards first evacuated were allowed the opportunity of taking in men, and the whole city was again full. A good many people had left, but all the wards had an opportunity of taking in people by the end of May.

24,261. You had no inconvenience from the wet season during this operation?—No, we had not. We had a very sharp shower of rain about the end of February, 1898, and that, so to say, put a good many people to trouble and inconvenience. There was also a good deal of cough, and the mortality was not at all high.

24,262. You mean the mortality from other causes than plague?—Yes.

24,263. You think it was low?—Yes, it was low; but even with that shower and the cough and all that, it was not at all high—not so high as one would have expected it in the city.

24,264. Did you notice if plague commenced in any parts of the town which, in their sanitary or any other condition were different from other parts?—I noted that the part where the plague first broke out was the part which is most unhealthy; where there is no drainage system.

24,265. But this part also had this condition—that it was nearest to the infected cantonment, had it not?—Yes. The people had begun to leave the other parts of the city, and there was no possibility of discovering the particular item of insanitariness. There are other parts of the city equally bad in point of sanitation, I admit, but still we had not an opportunity of gauging that condition on account of people beginning to leave of their own accord.

24,266. Where did they go to?—Mostly all the people camped in the fields about a distance of two or three miles from the city.

24,267. They were not specially under control in the fields, were they?—They were put under control by the Collector's staff. The Akbari Inspectors were put on. One reverend gentleman, Mr. Smith, was also put in charge of the outskirts.

24,268. Do you think that any of these people went further than the camps—went into the neighbouring villages or towns?—Yes, they did; not after plague had assumed an epidemical form, but at the time it had broken out.

24,269. Why did they run away in that way?—I suppose on account of the experience they had had in the cantonment and Sadr Bazar.

24,270. What point in that experience caused them to run away?—They came to know that in the Sadr Bazar people were being asked to go out and leave their houses.

24,271. Do you not think it was rather the plague measures than the plague itself that they feared?—I should think so.

24,272. Within your knowledge are there any instances of plague having been imported into a place previously non-infected by this running away of the people? When the people ran away from Nagar did those people who went into other villages or towns infect any of those villages or towns?—Not so far as I know. I do not remember, but there were cases in the fields.

24,273. You have described among your measures the making of openings in the houses?—Yes.

24,274. Why did you find that desirable?—Openings were made so that the rays of the sun could penetrate into the rooms, which were generally very dark.

24,275. What sort of ventilation is there, generally speaking, in the houses?—There are very few openings for ventilation in mud houses. If there are any they are very small. They are not suited to bringing in the rays of the sun direct. The best remedy was to have openings made in the roof.

24,276. Now we will come to the epidemic of 1898. What were the chief features of the commencement of this epidemic?—The chief features noticed about the 1898 epidemic were that rats were found, while they were not found in the 1897 epidemic. The Sisters of the S.P.G. Mission complained that they found a good many rats dying. We found that two girls were suffering from plague.

24,277. Were these the first cases which came to your knowledge?—Yes, in 1898.

24,278. Therefore, before these cases occurred there had been an observable mortality among rats?—We did not observe any mortality among rats in the city, nor outside. It is only that feature, the S.P.G. catching plague, that brought to our mind the mortality of rats in that direction.

24,279. And that mortality occurred before the first cases in that part of the town?—It is not within the town; it is just outside the town—2 miles or 1½ miles out of the town.

24,280. Is it within the Municipal boundary?—It is not strictly within the Municipal boundaries—it is a little further up.

24,281. Will you describe the introduction of plague into the Municipal boundaries?—This year we found some cases in the Maharwada. That is outside the city gate. We have not yet ascertained how that part of the city came to be infected this year. What we have found out is that the surrounding villages were first infected this year. That is one feature of this year

Khan Sahib B. S. Cardmaster.

7 March 1899.

which was rather peculiar. Before the city could be infected, most of the surrounding villages were found to be infected, and we were taking care not to allow these people to come in. The part that was infected last month in Nagar is the part called Maharwada. It is suspected that those people must have mixed with other villages, or that people from other villages that were turned out must have mixed with the people here. During the last three or four days we are marking one particular feature, namely, that the fields which had plague last year are now showing cases this year too. Though the city was free for a number of days—for a number of months even—cases cropped up in the fields; and it is not understood how the fields could be infected, but there was no infection in the city.

24,282. But there was infection in the surrounding villages?—Yes, there was infection in the surrounding villages.

24,283. Those are the chief features?—Yes.

24,284. Will you kindly describe what you did in this second epidemic—what were your measures—were they the same?—Yes, they were the same as on the previous occasion.

24,285. When did you effect evacuation during the second epidemic?—We only evacuated blocks. We have not turned out the wards yet. We thought, as it was simply beginning, we would try the system of evacuation by blocks; and we have so far succeeded in keeping in check plague in one part of the city, called Nepti Gate.

24,286. Has it been restricted to that part?—We found one case and one death in one part of the city in October, 1898. We evacuated about 40 houses, and turned out about 300 people. We were successful as regards that arrangement. Plague did not advance.

24,287. In that part of the city?—Yes.

24,288. What about the other parts of the city?—The other parts of the city also remained safe.

24,289. What has been the number of cases in this second epidemic?—Up to date we have had 37 cases.

24,290. Have these occurred in the city chiefly, or outside?—The number in the city is comparatively very small.

24,291. How many, do you know?—About five or six.

24,292. The 1898 epidemic has been quite unimportant?—It has, because we are safe.

24,293. At present you have nothing to cause anxiety here?—No.

24,294. These cases chiefly occurred in the encampments?—Yes, in the fields.

24,295. Where the people have voluntarily gone out?—Most of the people had left last year, and had built huts in the fields. They have not yet returned.

24,296. The people in the fields, I suppose, might quite well communicate with neighbouring villages?—They may, or the people in the neighbouring villages may communicate with them.

24,297. I presume that is including infected villages?—Yes.

24,298. So that there is no mystery about the origin of these cases in the fields?—I think it is rather a mystery.

24,299. What is the mystery?—The origin of it.

24,300. Do you mean the origin of any particular individual case?—From inquiries, we have learnt that though it is quite possible and probable that there may have been communication, still the people themselves say that they have not moved out nor have they allowed people to mix with them. People who are known to have come from infected villages are watched, and are not allowed to mix with other people.

24,301. How complete is the watching; is it impossible or even very difficult for them to go beyond the boundary that is watched?—It is difficult, but it is not impossible.

24,302. Have you formed any special views with regard to the methods of communication of plague?—I should think particularly by contacts.

24,303. Do you think that the communication is chiefly by human agency or by some other means?—Principally by human agency.

24,304. Have you any instance in which clothes, apart from men and women, have been the channel or the means of conveyance of plague?—I have not had any special opportunity of noting that. I have had reports like that, but I have no special knowledge of persons secreting clothes or concealing clothes and getting plague.

24,305. You had reports, but it did not come to your own observation?—No.

24,306. The official report would be very useful?—I have not traced that report out.

24,307. It is only an impression, therefore, in your mind that it may be so?—Yes. That is my impression from the reports I have received from people.

24,308. Do you think that rats have a share in the communication of plague?—Only from what I have heard and seen with regard to the S.P.G. Mission.

24,309. Only from that instance?—Yes.

24,310. Do you know if other animals besides rats have had plague?—I saw cats.

24,311. What do you think are the features which are most conducive to the spread of infection? You draw attention to floors, want of ventilation, and general insanitary conditions, do you not?—Floors of houses have much to do with the communication of plague. Most of the people here sleep on floors and move bare-footed in their houses, and therefore run the risk of infection. Roofs of houses here contain so many crevices and holes that they form good harbouring haunts for plague germs in spite of disinfection with perchloride of mercury. Want of ventilation is very healthy for the thriving of plague bacilli. Houses here are so constructed that they have very little ventilation, and even that is closed during the night. There are certain houses which even require a light in the daytime. Weak health and bad feeding also encourage plague. This was verified by the numerous attacks that took place amongst the Sali, Kosti, and Kongadi people. These were the people who had suffered most in the famine, and no sooner was famine over than plague overtook them in their half-famished state. Milch-cattle stables, unless they are built upon sanitary principles, with outlets for the proper discharge of urinary matter and dung, also prove very flourishing to plague, and, with this in view, the then Civil Surgeon, Dr. Stevenson, advised the Municipality to drive out all cattle and provide for them suitable stables outside the city.

24,312. With regard to the various steps you have adopted, which do you think is the most effective?—Evacuation.

24,313. You have a very clear opinion as to that?—I am quite positive.

24,314. I suppose it is a natural inference that the more complete the evacuation the more effective it is as a measure?—Yes, and much more if it is undertaken in the first stages of plague.

24,315. Would you express any opinion as to the value of disinfection in itself—of habitations, I mean?—I am rather sceptical about it.

24,316. On what grounds?—On the grounds of the construction of the houses in the mufassil towns. There are so many crevices and so many things to look after. I do not think disinfection with perchloride of mercury can thoroughly reach those crevices and holes which are found in numbers in the houses. However satisfactorily it may appear to be done it will not be perfect.

24,317. Have you any instance in which the value of perchloride of mercury has been tested and shown to be inefficient?—I cannot mention any specific instance.

24,318. You believe in the efficacy of the influence of sun and air?—Yes.

24,319. But you have no case in which you have established the insufficiency of chemical disinfection?—No.

24,320. Have you any knowledge as to the possibility of food substances conveying plague?—No.

24,321. None at all?—No.

24,322. You have had, I think, to entirely disinfect and clean this city twice?—Yes.

Khan Sahib B. S. Cardmaster.

7 March 1899.

24,323. What has been the general result of that upon the health of the city apart from plague?—I have found cholera disappear, and noted, particularly last year, that cholera had entirely disappeared. Generally speaking, we have cholera in July and August every year, and we have a mortality of about 50. I noted the complete disappearance of cholera last year.

24,324. Have you anything to say with regard to the water supply? What does the water supply of Nagar consist of?—Old aqueducts. Water is brought into the city under masonry galleries to a certain distance, and under a new scheme it is brought in in iron pipes.

24,325. Even since water has been brought here in that way cholera has been fairly prevalent until last year?—Yes.

24,326. Have you any statistics to show the mortality during the last two years as contrasted with any previous periods?—Yes.

24,327. Does that bear out your contention as to the increased healthiness of the city within the last two years apart from plague?—Last year, just at the time plague was raging—say from November to March—we did not get any complete statistics because the people were out in the fields. What was shown in the mortality statement last year was rather vague and I should not like to trust that.

24,328. This year?—This year we found mortality in certain weeks rising, and in certain weeks falling, but contrasted with previous years it was almost an average.

24,329. Then there is nothing actually to prove that there is increased healthiness, but only that cholera has diminished?—Yes.

24,330. I think you noticed something in connection with rats in this city after plague had appeared?—After the disinfection and evacuation of the city, a disappearance of the rats was noticed in 1898.

24,331. There are now almost no rats—they have been reduced greatly in numbers?—Yes.

24,332. I think you have already stated that in 1897 a mortality among rats did not precede plague?—Yes. In 1897 we did not mark the mortality among rats, and in 1898, so far as this city is concerned, there has been no complaint as to rats being found. There is only the S.P.G. Mission case where rats have been found.

24,333. Is there much overcrowding in the localities of this town within the houses?—In certain wards there is overcrowding.

24,334. Was there any observable relationship between the incidence of plague in these wards as contrasted with other wards?—In Ward No. 6, which is the most overcrowded part of the city, the mortality during plague time was high; but that ward has been inhabited by people who are more intelligent than the people in the other wards. The people left, however, as soon as they found that the other wards would have to suffer.

24,335. (*Mr. Hewett.*) You say that plague occurred in 1898 in the fields in which it took place in 1897. Do you mean that it occurred in the same hut or in the same collection of huts?—I am not sure whether the huts were dismantled last year and reconstructed this year, but the cases occurred in the same area.

24,336. Do you know whether the huts in which plague occurred last year were always disinfected?—I am not sure.

24,337. Might it be possible that the infection may have remained there?—It is possible.

(Witness withdrew.)

Mr. Mohanlal Hiralal called and examined.

Mr. Mohanlal Hiralal.

24,338. (*The President.*) I understand that you are a member of the Ahmednagar City Plague Committee?—Yes.

24,339. (*Mr. Cumine.*) You are a volunteer witness, are you not?—I was asked by the Collector to give evidence.

24,340. You are not an official?—No.

24,341. You have heard what Mr. Cardmaster told us?—Yes.

24,342. Have you any interesting facts to bring before us in addition to those he has given us?—In the year 1896, when the first cases occurred here, no steps were taken to disinfect the houses. The infection having come in the summer months it did not affect this town at all. There were six or seven cases, and we did not adopt any steps in 1896, because it was during summer. The plague did not remain here at all. The inmates of the same houses and the neighbouring houses were not affected. In the summer climate even importations had no effect here. It was in the winter season when plague came in 1897. It was about the end of January that the whole town was evacuated. Mr. Cardmaster said it was about the end of March that the whole town was evacuated, but I think it was about the end of January. For nearly three months the inhabitants were out. The opening of the houses to the influence of the sun had a very good effect. I do not believe in the process of disinfection with perchloride of mercury. I know of my own knowledge that it was not fully carried out according to the directions of the Civil Surgeon or the medical men. The houses are so peculiarly constructed that every portion of them cannot be satisfactorily disinfected, and the workmen did not do the work satisfactorily. Still, the opening of the houses, and leaving every room open to the rays of the sun had the desired effect. I am inclined to think that the sun did the work of disinfection more than the perchloride of mercury. That is my impression about it. This year we have simply had sporadic attacks—cases here and there.

24,343. Why did not these sporadic cases spread plague?—In my idea it is owing to the effect of last year's disinfection, namely, the houses having been opened up to the sun. The cases came to our knowledge very early, and steps were taken to remove those people. The infection could not travel.

(Witness withdrew.)

Mr. Edulji Rustomji, called and examined.

Mr. Edulji Rustomji.

24,344. (*The President.*) You are Vice-President of the Ahmednagar Municipality?—Yes.

24,345. And Chairman of the Plague Committee?—Yes.

24,346. (*Mr. Cumine.*) You go over pretty much the same ground as Mr. Cardmaster, do not you?—Yes, very nearly the same, except that in my précis of evidence I have noted some special facts to mention.

24,347. Do not go over the same ground, but kindly mention any special things that he did not touch upon?—I have in my précis mentioned that infection came first from Bombay, subsequently from Poona, and lastly a case from Kirki. I have given all the details, and described how the first case, an imported case, came into the city of Ahmednagar. One of the Padamsalis, by name Ramaya, came from Bombay. I have stated all about that in my précis. I have also stated in my précis that the climate was peculiarly chill and cold about the time that plague was raging in Ahmednagar, and also that at the same time there was a scarcity of water. The weather and the atmosphere, although chill, was dry. I have also described, at considerable length, how the city was first, block by block, evacuated as it became infected, and subsequently by wards, as has been described by Mr. Cardmaster. I might specially mention that while the system of opening up the houses was being carried out, it came to my notice that there were certain houses in this very town which required candle-light to get a vision in, even during the day, and those houses were the most typical instances which I have, where air and light had never got to them since they were constructed. These houses, such as those I have described in the Cloth Market, were constructed ages ago. These houses were specially treated in regard to ventilation and light, the owners were made to provide windows and roof ventilation, and light from the roof

Mr. Edulji Rustomji.

7 March 1899.

was also insisted upon. Another thing that Mr. Cardmaster has not stated, is, that while we were disinfecting and opening up the houses for the benefit of the people, we had a very valuable agency, and perhaps a very honourable one too, in having our head officials—the Executive Engineer, the Civil Surgeon, the Assistant Collectors, and the District Superintendent of Police:—all these had divided the city wards amongst themselves, and they were in their divisions personally and zealously superintending the operations of disinfecting and opening up the houses. These officials were subsequently aided, in order to see that each house and each room was thoroughly disinfected, by European soldiers, and native soldiers were afterwards brought in. Of course, by their presence, I am thoroughly convinced, on inquiry, that there was not a room left in any house of the town, which was not thoroughly done up. I have also noticed in my précis that the Municipality had to do this at no ordinary inconvenience as regards its finances.

24,348. What is the result of the thorough cleaning-up that the city got?—It has reduced the ordinary mortality of the town as compared with the previous five years.

24,349. Have you noticed whether people who sleep on the ground are more liable to catch plague than those who sleep on beds?—Yes, that is my experience of it. I found that several of my own servants, and other people whom I have known, and also on inquiry, have had reported to me that most of those people who were actually sleeping on the ground got attacked with plague and died.

24,350. Have you noticed whether people are more liable to catch plague if they sleep on one floor of a house than on another?—I think so. That is my experience, but it is not based upon a very large number of observations, but I know in one or two cases that people who slept on the higher floors did not get plague, although they were contacts.

24,351. Is there, in your experience, a particular danger in natives going into infected houses without shoes on?—Yes, there have been two instances I have particularly noticed in the case of people going in to do repairs to the S.P.G. Mission outhouses.

24,352. Will you tell us what you think are the best methods of keeping plague out of a district?—Observation camps, disinfection stations, medical examination stations, and a system of medical surveillance are, I think, excellent modes of keeping plague out of any station.

24,353. And immediate evacuation of infected places?—Yes.

24,354. (*Mr. Hewett.*) Have you Voluntary Committees at present to keep under observation people who arrive from outside?—We have a Committee appointed to visit the railway station, one member of the Committee going every day in the week and assisting the Hospital Assistant to examine the arrivals at the station.

24,355. If people come from outside now do you know where they go to live?—Yes, we keep a register at the railway station, and keep the village officers, and the officers of the talukas, the Mamlatdars, informed of people going to their talukas, having arrived by rail.

24,356. Is that what you mean by medical surveillance?—The people that come from infected places are asked to go for medical examination to the City Hospital for 10 days after their arrival.

24,357. That holds good in the city?—Yes. We generally find out if any people are actually suffering. I think there was a case so found, of people examined at the hospital—that there was a case of plague amongst them.

24,358. (*The President.*) Do you remember what was the total number who were in the camps outside the city, at any one time?—Nearly the whole of the city was turned out, and I should think that over 20,000 must have been living in the camps outside.

24,359. Then there are 16,000 not accounted for?—What I think had become of them, was that they had gone to other places. I know some of the Marwaris had gone to Marwar, and some had gone to Gujarat, and some had gone to other places, but I do not know whether the whole of the 16,000 had gone in that way.

24,360. You described the measures adopted in evacuated houses. In some cases you made structural alterations that were required?—Yes.

24,361. Can you tell me whether the people have made use of those structural alterations that you introduced?—We made them provide permanent windows, and openings in the roofs, but in several cases I found they had closed them up, by hanging clothes and pardahs over them. We then asked them to open them up again. It appears that most of the people who live in those houses do not like very free ventilation, and somehow or other, I found in some cases they had closed up the windows that I had provided—only temporarily—they had not permanently closed them up; they could be opened at will.

24,362. Do you think that these permanent improvements will be taken advantage of by the people in time?—I think that the better class of people have been using these windows, and that only the poorer classes tried to shut them up by hanging clothes and curtains and pardahs, or something like that, over them. I think, however, that they will gradually come to appreciate the value of light and ventilation. Of course, in some cases in which the houses were very dark, I have seen that the people kept them open.

24,363. Will you kindly tell me what is your opinion as to the most successful method of dealing with plague epidemics?—From what I have seen from the beginning to the end of plague in Ahmednagar, I am fully convinced that evacuation of infected houses and opening them up to sunlight and ventilation and whitewashing and otherwise thoroughly cleaning them up is the best remedy to escape wholesale ravages by plague; that plague sticks most and does greater mischief in dark, ill-ventilated, dirty houses and localities, and can be stamped out of a sanitary house much easier and quicker; and that by people living in the open, they not only escape attack of plague but get better and stronger as regards their ordinary and general health and constitution. I have heard several people say they have been feeling stronger and better after their stay out in the open in huts and sheds.

(Witness withdrew.)

Major C. F. Willis, I.M.S.

Major C. F. Willis, I.M.S., called and examined.

24,364. (*The President.*) You are in the Indian Medical Service?—Yes.

24,365. And are a Doctor of Medicine, and a Member of the Royal College of Physicians?—Yes.

24,366. What is your official position here?—Civil Surgeon.

24,367. (*Mr. Hewett.*) Can you give us some general idea of the course that plague had pursued in the villages outside Ahmednagar?—I can only tell you with regard to the latter part of the year. I was not here during the first; I was up at the front then. It commenced this time at Chichondi, a village 13 miles away from here.

24,368. When was that?—I cannot tell you the exact date; it was run by the village authorities. It was about October or November.

24,369. Did it extend from there?—It did not extend at all from there. The people evacuated into their fields, and the plague did not extend. There was no plague in the villages near.

24,370. What was the next place affected?—Savedi, about two miles from here, and about half a mile beyond the Mission, where plague first appeared. There they had a lot of cases. The cases had been returned as usual as anything, until I went there and found two or three cases of plague. The usual measures were then taken, the village was evacuated, and the people turned out into the fields, and that village has been thoroughly cleared out, and no spread of plague, I think, took place from there.

24,371. Have any of the other villages in the neighbourhood of the town been affected?—Towards Poona, there was another village called Khedgaum, which had

plague there. That was about the third village. They had several cases, and from there I think it spread to other villages, to another village called Sonawadi, a village about three or four miles further on.

24,372. Do you know the maximum number of villages attacked at any one time in the district?—I think the maximum would be five. I do not think, even then, they all had cases at the same time, for the first two or three villages have been free from plague now for several weeks.

Major C. F. Willis, I.M.S.

7 March 1899.

24,373. Then there has been no serious outbreak?—No; only one or two cases occur now and then.

(Witness withdrew.)

(Adjourned till Wednesday, 8th March, at Nasik.)

At The Collector's Office, Nasik.

SIXTY-THIRD DAY.

Wednesday, 8th March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. R. A. L. MOORE, I.C.S., called and examined.

Mr. R. A. L. Moore, I.C.S.

8 March 1899.

24,374. (*The President.*) I believe you are in the Indian Civil Service, and Collector of Nasik?—Yes.

24,375. And you occupied a similar position in Surat?—Yes, I did.

24,376. Where you had an opportunity of seeing two epidemics?—I did; at the beginning of 1897, and from the middle of 1897 up to May 1898.

24,377. Were these the only two epidemics that occurred in Surat?—Yes; in fact, I saw all the plague that occurred in Surat.

24,378. The first epidemic, I think, commenced in February?—It did.

24,379. And terminated in May?—Yes; May 1897.

24,380. Can you tell us what part of your Collectorate was chiefly affected in the first epidemic?—The chief place affected was Rander. As a matter of fact, putting aside a few imported cases, plague began at Rander. That is a town on the other side of the Tapti, opposite Surat, with a population of about 10,000 people. It spread from there, and subsequently, as far as I can remember, in the month of March it began at Bulsar. It chiefly prevailed at those two places during the first epidemic.

24,381. Can you account for its introduction into Rander?—I made inquiries, and, as far as I can gather, it arrived in this way. There was a vakil who lived at Rander whose wife had a brother at a Gaikwari village called Wariav. The brother came from Bombay to Wariav, and died of plague. While he was ill, this lady, the wife of the vakil, went on a visit of condolence to her brother. She returned to Rander, and herself developed plague and died. From that the disease spread throughout the town. That was the result, from inquiries that were made.

24,382. How long previously to its becoming indigenous did this importation occur?—As far as I remember, a fortnight. I ought to say that when this imported case occurred I was out in the district. I received, first, an anonymous petition and subsequently a letter from the Hospital Assistant at Rander, stating that he believed that there was plague in the town, and that it was being concealed. I immediately came in, and very shortly after my arrival plague became very evident.

24,383. You did not, therefore, get very early information about this importation?—No, not for several days after it occurred. I was in the district, and there was no plague at the time.

24,384. The information was not early enough to allow you to deal with the first case?—It was not dealt with at all.

24,385. Previously to its becoming indigenous was there any marked mortality amongst rats or other animals?—None that I was aware of.

24,386. If there had been, you would have heard of it?—Yes, if there had been any marked mortality.

24,387. After plague became indigenous, how did you treat it?—At the beginning we acted in this way. We had a field set apart, and in this field we put up a Municipal Plague Hospital, and we also allowed any castes who wished to do so to put up their own hospitals. Some castes did put up their own hospitals. Anybody taken with plague was removed to the Municipal or Caste Hospital, as the case might be, with two attendants. At first we started an arrangement of having the women all in one special building, but that was not subsequently carried out, as it was found impossible to separate the sexes owing to the fact that the attendant on a woman would be a male, and *vice versâ*. The husband would come with the wife, and the wife would come with the husband. Then we had the plague house vacated, and all the tiles removed and all the doors and windows opened and barred by bamboos. The place was then thoroughly doused with a solution of perchloride of mercury, one in 1,000, out of a fire engine. At the beginning I also had all the floors dug up, they were chiefly earth floors, to a depth of about six inches and taken outside the town and burnt. That was done to the plague house, and also to the houses on each side. If that was not found sufficient we proceeded to turn out whole localities and treat them exactly in the same way, except that we did not dig up the floors.

24,388. What was the proof of its not being efficient?—That in spite of the house being cleared out, perhaps in a day or two, the next house, or the next house but one, would develop plague, and so on down the street. When I found plague going down a street, I turned the whole street out.

24,389. Was that more efficient?—Yes, I think so.

24,390. That would seem to imply that plague still extended?—Yes, undoubtedly it did still extend.

24,391. In the first place the extension appeared to be by contiguity?—Yes. Possibly, I am not conveying a right impression. The plague did not spread actually to the next house, but it would spread from one house

Mr. R. A. L. Moore, I.C.S.

8 March 1899.

to three or four houses down, where there were relations or friends living of the people from a plague infected house. The plague does not begin in No. 1 house, and then go to No. 2, and No. 3, and No. 4. It will begin, say, in No. 1, and then go to No. 4, where the people in No. 1 have some friends or relations.

24,392. Therefore, it may extend across a street?—Yes, or to another street altogether.

24,393. Do you think the method of conveyance is by human agency?—Yes, by persons, and also by concealment of infected kit, clothes, and such like. People, when they are ordered to bring out kit and to have it disinfected, or, in a case of clothes belonging to the patient, to have them burnt, often conceal a part, and it is smuggled off by a friend or neighbour, and the friend or neighbour by so doing takes plague to his own house. I have found that out.

24,394. That house being at a considerable distance?—Yes, it may be.

24,395. Have you any cases in which it has been at a considerable distance?—Yes.

24,396. And you think it was carried in the clothes?—It was in property carried from an infected house.

24,397. Where it was not probable that it was carried by human agency?—Where it was not probable.

24,398. But, of course, you could not altogether eliminate that?—Yes, that is my impression after a couple of years' experience.

24,399. In a general way, was a large proportion of the population affected?—Yes, a very large proportion, certainly.

24,400. Was the mortality considerable?—The mortality was very considerable. I cannot tell you exactly what it was, but I should say it was four-fifths; 80 per cent. of those attacked.

24,401. Perhaps, in a similarly general way, you could give the proportion of those attacked to the population?—As I have had three epidemics to deal with, I get confused in my figures, and I should not like to say.

24,402. What have you to tell us with regard to Bulsar?—With regard to Bulsar, I may say that I had to supervise plague matters generally, and visit places, but the actual work was done by Captain Dyson, as he was then, the Deputy Sanitary Commissioner. The arrangements which I have described with regard to Rander were very similar to those carried out at Bulsar.

24,403. That is to say, the extreme measure was partial evacuation and not complete evacuation?—At first, and then, subsequently, streets were evacuated. The whole town was not evacuated.

24,404. Now we come to the second epidemic, which I think also involved three towns?—Yes, Rander, Bulsar, and Surat.

24,405. Which was the first of these three places affected in the second epidemic?—The first place was Surat in the second epidemic.

24,406. Do you know how plague was introduced into Surat?—Yes; I believe it was introduced by people coming from Bombay, especially people of the Ghanchi caste.

24,407. Who are the Ghanchis?—The Ghanchis are oil pressers.

24,408. Had they fled from Bombay?—They came from Bombay.

24,409. Because plague was in Bombay?—Yes, because plague was in Bombay. I should mention that Surat has a large business connection with Bombay. There are a large number of low castes in Surat who go for service to Bombay; for instance, a large number of people came from the caste called Surtis; they go as syces, cooks, and butlers to Bombay. They became infected in Bombay, and then came back and spread plague in Surat.

24,410. At about what time was the second epidemic?—The second epidemic in Surat began in August 1897—the mortality began to rise then. I am speaking from memory but I think I am right. I left Surat in May, 1898.

24,411. Was the course very much what you have described in the case of Rander?—There was a slight epidemic in the beginning of 1897 in Surat, I suppose about 150 cases. That was at the same time that plague was going on at Rander, and was introduced from Rander. It did not spread much during the first epidemic in Surat. We were very rigid in our measures. We burnt down some of the plague houses altogether. When plague first started in Surat we had houses pulled down and burnt. The plague did not spread much at that time, and then it stopped altogether.

24,412. In addition to partial evacuation, you burnt down some of the houses?—Yes.

24,413. It was a small epidemic?—Yes, about 150 cases.

24,414. Do you remember when it ceased?—I think it ceased in Surat in May 1897.

24,415. Between May 1897 and August 1897 the town of Surat was absolutely clear?—Yes, there might have been a few dropping cases perhaps; as a matter of fact I think there was one case, which occurred in July.

24,416. Was there any case which you could not trace to importation?—No, I think there was one imported case in July, to the best of my recollection, between May 1897 and August 1897 in Surat town; but there was no indigenous plague. Then, in August, the mortality began to rise rapidly.

24,417. Will you describe what measures you adopted in Surat after August?—Plague began in the middle of the rains, and, consequently, we were in a great difficulty. We could not go in for evacuation to any great extent, because we had nowhere to put the people. We did, however, turn out any plague cases we had, and removed them to the Municipal hospital, which we started near the railway station, at a place called the Parakh Dharamsala. We made the same arrangements as before. We allowed two attendants to attend upon each sick person, and we disinfected the houses, but we did not go in for segregating the contacts, because we had nowhere to put them. The people had to turn out of their houses on account of the disinfection. Some of them spread through the town, and some of them were provided with quarters in a building which was put at our disposal by a native gentleman, the Bakshi Sahib of Surat—the leading Musalman gentleman in the place. Then, aftera bit, the different castes asked me to be allowed to start their own hospitals, to which I agreed on condition that they should pay all the expenses, and allow the hospital to be under the supervision of the Civil Surgeon. They were to have their own Medical Officers, but to be under the supervision of the Civil Surgeon. Each religion did start its own hospital The Hindus had one, the Parsees had another, the Shiah Musalmans had another, and the Sunni Musalmans a fourth. Finding that there was great concealment, I started house-to-house search parties. Each party consisted of one or two European and some native gentlemen and a party of police. We went round and searched all the suspected quarters. I am bound to say that, as far as the search went, it did more harm than good, because it was almost impossible to conceal from the people where we were going to. The consequence was that they removed patients before we came, and thereby infected fresh houses. Plague went on, and the mortality continued to rise until November, and then Mr. Wingate, who was then the Plague Commissioner, arrived. He said that, in his opinion, we ought to start the ward system in Surat, which we did immediately; that is to say, the town was divided into nine wards. At the head of each ward there was put a European ward officer. They were all officials, except one, Mr. Page—the Bank Agent—who very kindly volunteered. Then, as far as possible, I gave each Ward Superintendent a European assistant, also a Government official, and a lot of honorary assistants in the shape of native gentlemen, who volunteered for the work. In this matter of volunteering I ought to say that the Parsees and Muhammadans were especially good; the Hindus were less ready to help. Under each Ward Superintendent there was a special staff put. We had for each ward one or two fire engines for disinfecting, with a gang of coolies under a Muccadum. We also had a number of police, and we had a staff of sweepers. The Ward Superintendent and his Personal Assistants were supposed to recognise plague as a rule. If they had any doubt they either sent for the Civil Surgeon or the Assistant Surgeon, who was put especially on that duty, and he decided whether that case was one of plague or not. If the case was decided to be plague, the plague patient was removed either to the Municipal Hospital, which we started in what was really the Civil Hospital, with an extension in the High

School—the Civil Hospital being removed into a part of the Jail—or else the patient, if he chose, was taken to his own caste hospital. In case of concealment, by way of punishment, people who wished to be taken to their own caste hospitals were not taken there. Supposing a Hindu concealed a case, and said he wished to go to his own caste hospital, by way of punishment he was taken to the general hospital. We had also a segregation camp for contacts; that is to say, all persons who were living in the house of the patient were taken to the segregation camp which was outside the city, and put under a pensioned Sergeant-Major of Gunners.

24,418. Was that during the rainy season?—It was in November, after the rains had stopped, and after Mr. Wingate's arrival. The segregation camps consisted of tatti huts built by the Municipality, and food was provided for all the people in the segregation camp, and to the poor, also, blankets and warm clothes were provided out of a charitable fund which I got up, and to which the native gentry of Bombay and Bhawnagar, especially, subscribed freely. They were kept in a segregation camp for 10 days, and if they developed no plague they were allowed to go; but they were not allowed to return to their houses in the city without a written order by myself.

24,419. They were allowed to go away?—To go where they pleased. That was after 10 days' segregation. We also found that it was not sufficient to turn out one or two houses when plague occurred, so we turned out whole streets, and then, after a bit, we turned out several streets, whole quarters in fact, and we camped the people down in what we called health camps all round the city. We had four Municipal health camps under official supervision, and there were a large number of small camps which were constructed by the people of their own accord. With regard to these voluntary camps, I had to close them subsequently, as I thought they were sources of spreading infection. There was no supervision over them, and the people used to go into the town and visit plague-infected relations, and come back again and generally spread infection. I therefore had to close these camps subsequently. In the four large health camps the people who had any means had to build their own hut, but people who had no means were provided with matting by the Municipality. In the case of widows and such like, huts were built for them. In each camp we had a staff of police and a staff of sweepers to keep the latrines in order, and we had a Sanitary Officer over the camp; we had Superintendents who were either Eurasians or Parsees. They also had a staff of Karkuns to keep the register of arrivals and give passes to people to go in and out of the camp. They were allowed to go out in the daytime, but they had to come back at night to sleep.

24,420. What is the maximum number of people you had in these camps at one time?—Of all sorts, both in the Municipal and voluntary camps, we had 35,000 at one time.

24,421. Inhabitants of Surat?—Yes, inhabitants of the city.

24,422. Had you many cases of plague in the Government health camp?—We had in one camp especially, which was occupied by the people I mentioned, the Ghanchis, and also by the low caste of people called Golas, rice-pickers. We had to move the site of that camp twice and to burn down the huts and burn the ground. This was partly due to the fact that these castes were excessively filthy in their habits, and partly to the fact that they were allowed to go to the town during the daytime to work for their living, but in reality they used to hire themselves out as plague corpse bearers.

24,423. Was there any provision to prevent overcrowding of the Government huts; was there any limit to the number of people in one hut?—Yes, I think I am right in saying that the maximum number allowed in one hut was five. If the family consisted of more than five, they were given another hut just adjoining.

24,424. You spoke of 35,000 being camped outside the city?—Yes, at one time; that is in round numbers.

24,425. What was the total population of the city?—110,000. We had about one-third of the population camped out.

24,426. And a considerable number remained in other wards?—Practically, the remaining two-thirds. We took great precautions against people running away from Surat.

Mr. R. A. L. Moore, I.C.S.

8 March 1899.

24,427. Were those precautions successful?—Yes, in preventing plague spreading out of the Surat district, but not in preventing people going out of the city and into the villages. We could not stop that, but we did prevent plague from spreading from the Surat district. That I am prepared to say.

24,428. Do you know the total number of cases during the second epidemic?—In round figures I should think it was about 2,500 or 3,000.

24,429. Do you know the mortality?—The mortality was about the same, 75 to 80 per cent.

24,430. Did this measure which you adopted again, consisting of only partial evacuation of the city, do much good in your opinion, or not?—I think it lessened the number of cases.

24,431. But it did not stop the progress of plague?—It distinctly did not stop plague, because plague went on from August 1897 to May 1898.

24,432. You began to adopt extreme measures in October 1897, and plague continued till May 1898?—Yes. It had stopped entirely before I left Surat. I did not go until it stopped. I left Surat on the 25th May. Plague stopped early in May.

24,433. In the case of the whole of the houses which had been occupied by plague patients, was disinfection quickly carried out?—Yes, certainly. It was generally carried out the same day, or, at any rate, the next day. We had the fire-engines filled with the mixture of perchloride of mercury continually going round the streets.

24,434. Was it soon after that that the houses were opened up so as to admit air and light?—Yes; the houses were opened up immediately, and they were swept out too. What we did was this. We opened up the house, first swept it out, and then doused it with this mixture.

24,435. What did the opening up consist of?—In taking up nearly all the tiles, throwing open the doors and windows, and barring them with bamboos. In the case of people being recalcitrant, who would not open their doors and windows, we took the doors off their hinges.

24,436. After you commenced evacuating large areas, what treatment was adopted in the houses which were evacuated where there had not been plague cases?—Practically the same.

24,437. Disinfection and opening up?—Yes; and another additional step was taken, namely, the official organisation whitewashed all the houses in which plague had occurred after they had been disinfected, and a general order was given to the populace that, in the case of houses not actually infected with plague, the owners should whitewash them. Nobody was allowed to return without whitewashing their houses.

24,438. Have you any towns in your district where complete evacuation was carried out?—We had no towns; we had villages.

24,439. Can you remember any examples of the complete evacuation of villages; do you remember the general results sufficiently to be able to tell us whether complete evacuation was more promptly successful than the partial evacuation which you have described?—There was one village near Surat, called Umra, which was evacuated, and a place called Adajan which was evacuated.

24,440. Let us take these two places. What result did you obtain by that complete evacuation?—I remember the case of Adajan more particularly as I paid several visits there. I was afraid it would be a stepping stone between Rander and Surat. I cannot say that evacuation completely stopped plague, as dropping cases went on afterwards.

24,441. How do you account for these dropping cases?—Some of the people were infected before they left the village; others, or the same people, took out infected kit, which had belonged to people who had taken plague in the village, and then they developed plague when they got outside. Their friends and neighbours went and visited them, and if one of them died, his caste people came and sat round him and lamented, and accompanied the corpse to the burning pyre.

24,442. There were a few dropping cases?—Yes, cases went on.

Mr. R. A. L. Moore, I.C.S.

8 March 1899.

24,443. You spoke of people having gone out who were already infected; these would develop plague in the next few days after evacuation?—I cannot say that. It went on. It is not as if cases occurred within ten days and then stopped. It went on and on.

24,444. You found there was a great deal of inter-communication?—Certainly. When people are camped out it is impossible to stop them.

24,445. Inter-communication with the infected places—with Surat itself?—Yes; people used to go into Bandar from Adajan, which is two miles away.

24,446. Have you had any experience of inoculation?—None at Surat, because there was none. At least, I remember two cases. The result of one was rather unfortunate.

24,447. Had you any experience of inoculation at Bulsar?—Yes. That was during the second epidemic there. There was a very keen and intelligent Parsee Assistant-Surgeon, Dr. Dadachanji. There were two distinct epidemics at Bulsar, the first of which, as I said, was run by Captain Dyson, and the second was run by the Assistant-Surgeon, Dr. Dadachanji. For a long time the latter managed to keep plague out of Bulsar. With my permission he put on very strict quarantine and for a very long time kept plague out. But at last a man sneaked away from Bulsar to go to a marriage party at Bilimora. He came back and developed plague, and started the plague in Bulsar after three months safety through quarantine. When it was finally started, Dr. Dadachunji asked to be allowed to start inoculation, and I said if he could get the consent of the people, so that there would not be any ructions, I had no objection, and consequently he did get some people, who had been instructed by Professor Haffkine, to come up and perform the inoculations. As far as my experience of inoculation at Bulsar goes, it comes to this. I went down and made examinations, and I found the case mortality was about 25 per cent, but plague went on; that is to say, inoculation apparently saved a number of people from dying, but it did not prevent plague from spreading. That is the general impression I got there from what I saw of inoculation.

24,448. What is your general opinion as to the value of disinfection by chemical agencies?—I think it is not worth the money spent on it.

24,449. Upon what grounds do you express that view?—I consider evacuation and leaving the houses thoroughly open for a month equally effective. Unless disinfection is done under skilled supervision, I consider it so imperfect as not to be effective.

24,450. Have you any data to give us which would illustrate what you say?—I can give you the data of the present outbreak in Nasik—the plague which is going on now. We have had no disinfection throughout the district. In the villages, the plan I have gone on is this. I have sent round circular orders to all the Mamlatdars to have weekly reports from the village officers with regard to the mortality of the village. If the mortality rises, or two or three deaths occur in a house, they immediately go and examine the village with the Hospital Assistant, and if they find a case of plague they report it to me. I then send an evacuation order, and the village is turned out at once; the houses are all left open, and if it is a plague house, the doors are taken off and barred with bamboos. The people are not allowed to return until I give a written permit. If they do return they are prosecuted. I do not give a written permit for a month after the last death or recovery from plague. I found that system worked quite as well as disinfection. With regard to what I have said about the imperfectness of disinfection, I speak from personal experience. When I was in Surat, it was my daily work to ride round the city and examine the houses which had been disinfected. I frequently found that a room had been left undisinfected, or, perhaps, the walls had been done and the floor left untouched, or the ceiling had not been disinfected, and suchlike omissions; parts of the house had been soaked, while the rest was comparatively dry. I also found mistakes in the mixing of the solution.

24,451. Have you got any instance of a place in which plague occurred after it had been disinfected by chemical agencies?—I had one or two cases occurring both in Bulsar and Surat, but I cannot give you the names. A few cases of that sort did occur. It is my general recollection.

24,452. Cases in which houses had not been opened up, but only disinfected?—I will not say that—I think both. They had been both disinfected and opened up.

24,453. Then it seems to tell against both?—Yes, it does. The idea of disinfecting without opening up was not adopted at all in Surat. Dr. Dyson when in Bulsar, as he reported to me, did adopt that arrangement. That is to say, he turned the people out for 24 hours, thoroughly disinfected the house, and put them back again. I have a very strong impression that in those cases plague recurred in some of the houses in which the people were put back.

24,454. Have you got any cases in which houses were thoroughly opened up, and in which no disinfection by chemical agencies had been adopted, in which plague had occurred?—No, I have not noticed any instance of that sort.

24,455. What is the period of time required for disinfection by the free access of air and light?—I have always gone on the principle of at least one month; the more the better, but at least one month.

24,456. What, in your opinion, are the most effective measures in dealing with an epidemic?—In my opinion evacuation, and thorough ventilation of all infected houses for a month, kills plague.

24,457. Do you still agree with the whole of the last paragraph in your précis:—"The towns have been saved "by the introduction of the ward system into them all, "and the villages have been dealt with as in Surat by "prompt and entire evacuation with ventilation (but not "disinfection) of houses. I have discarded disinfection, "because of its expense and uncertainty unless executed "under skilled supervision. In my opinion evacuation "and thorough ventilation of all infected houses for a "month kills plague"?—I stated there that "the towns "have been saved by the introduction of the ward "system into them all." That was true when this was written—as a matter of fact apparently the towns had been saved, but unfortunately, since writing this, plague has broken out in Nasik, Igatpuri, and Sinnar.

24,458. What was your reason for discarding disinfection?—I have discarded disinfection because of its expense and uncertainty unless executed under skilled supervision.

24,459. In connection with your plague measures in Surat, did you undertake any operations to improve sanitation?—We closed several thousand pit privies with fresh earth, allowing the householders to construct open privies over them. These pit privies were in the ground floor of the houses either inside or just outside the house wall. They were cleared at irregular intervals; in some instances they had not been cleared within the memory of the present owner, and were very often in the immediate proximity of a well from which water was taken for drinking. An attempt was also made to clear away a crowded rookery inhabited by Golas (rice pounders) by offering them other sites (free of charge) as well as a certain amount of free building material. The attempt failed, as the Golas refused to move, and the Municipality were too poor to apply the Land Acquisition Act.

24,460. (*Mr. Hewett.*) How many villages were infected?—There a great number of villages infected, especially in Chornsi taluka, round Surat. There were two parts of the district in which a large number of villages were infected. There was the Chornsi taluka round the city of Surat, and part of the Bulsar taluka—that is the south of the Bulsar taluka round the town of Bulsar. That was undoubtedly due to traffic between the villages and the two towns respectively.

24,461. Have you any idea of the number of people who left Surat?—Yes, I made a calculation and I estimated that about 10,000 people had gone away. We had a pass system.

24,462. Those who left went away on passes?—Yes, on passes. A few may have gone before, but the great majority went away on passes.

24,463. You do not think many got away without passes?—No, I do not think so.

24,464. How many villages are infected in the Nasik district?—At present about a dozen including three Municipal towns.

24,465. Have there been a number of villages infected in the district at any time?—From the beginning of this epidemic I suppose there have been 25 towns and villages infected altogether.

(Witness withdrew.)

Lieut. A. N. DAVIDSON, I.S.C., called and examined.

Lieut. A. N. Davidson, I.S.C.

8 March 1899.

24,466. (*The President.*) I believe you are occupied with plague work in Nasik?—Yes.

24,467. (*Mr. Hewett.*) How long have you been employed here?—Since the 13th December 1897—roughly, 14 months.

24,468. What is the population of Nasik?—At the beginning it was 24,000 or 25,000.

24,469. When you came here in December, 1897, was there plague in the town?—Yes.

24,470. To what extent?—It averaged eight cases a day. The greatest number that I remember in any one day was 13 cases and deaths.

24,471. Can you give the total number of attacks and mortality in the town up to date?—In the first epidemic there were 501 attacks and 384 deaths, and in the second epidemic 182 attacks and 149 deaths up to date.

24,472. How long did the first epidemic in which there were 501 cases last?—It commenced in October. There had been imported cases in the town previously.

24,473. When did the indigenous cases begin?—In October 1897, plague was declared to be indigenous.

24,474. When did the first epidemic terminate?—The last three cases were in March, 1898.

24,475. In dealing with that epidemic, did you make the people evacuate infected blocks?—Yes.

24,476. How much did you evacuate when you got a case of plague?—When we had a few cases in any block we evacuated the block.

24,477. When you evacuated a block, did you put the people into the segregation camp or did you allow them to go where they liked?—A camp was made and they were told they might occupy it. I should think not 10 families occupied it; they went where they wished.

24,478. Did any proportion of the people leave the town altogether?—A very small proportion. I was employed on plague work in the fields for some time.

24,479. Having got the people out of their houses, did you take measures with respect to the infected locality?—Every house was disinfected with perchloride of mercury.

24,480. How long after the disinfection were the inhabitants allowed to come back to the town?—Two or three months, in my experience.

24,481. Did you allow them all to come back?—The people who were turned out first were Musalmans and Kalals. They were out for some time. They would not come in when they were first allowed to do so, because their clothes had to be disinfected.

24,482. You insisted on the disinfection of the clothes on going out and coming in?—Not on going out; on returning, we did.

24,483. You allowed some of them to return within three months, I believe?—Yes.

24,484. After the close of the epidemic in March, did you have any dropping cases?—There were two cases. There was one case in the Collector's compound and one in the Abkari Inspector's compound. They were friends—one a syce and the other an indoor servant.

24,485. How were they infected?—I do not know.

24,486. Did these cases occur in houses in which there had been already cases of plague?—No; there had been no previous cases. The last case in March occurred in a house in which there had been no previous case.

24,487. Did these cases you refer to occur in March?—Towards the end of March.

24,488. After the end of March, when you considered that the epidemic was over, what interval was there before you had another case of plague?—I think we had an imported case in August or September from Trimbak.

24,489. Is that a town in this district?—Yes, about 18 miles from here.

24,490. What did you do when you got an imported case?—We sent it to the hospital, together with the contacts.

24,491. Did you do any disinfection?—There was no disinfection this year. We opened the doors and windows and took off the roofs and barricaded the doors on the ground floor.

24,492. How long did it take for plague to become indigenous the second time?—We had an occasional imported case until 14th January 1899. Towards the end of January it became indigenous. I received information about two weeks previously that plague was being concealed in a portion of the city which did not belong to me, and I reported that to Mr. Menzies.

24,493. Do you remember whether the population of the city, in the interval between August and January, was above or below normal?—About normal, I think.

24,494. The second epidemic is going on at present?—Yes.

24,495. Have you been proceeding on the same principle of evacuating blocks?—No evacuation has been carried out at all. The people have been advised to leave the city.

24,496. What action do you take when you find a case in a particular house?—We have sent the case to the Plague Hospital and we have all the contacts removed.

24,497. You have done nothing to the house?—Only opened it up.

24,498. Since you have adopted this plan of only opening up the house and not disinfecting it, have you allowed any people to return to the houses so treated?—No.

24,499. So that you have had no opportunity of finding out whether it is an effective way of disinfecting houses?—No. People have been working in the house by day and cleaning the house, and no case has occurred among them. None of the people turned out of their houses have gone back to live in them.

24,500. Even though you had gangs working in the house, would it necessarily follow that the house was free from infection?—No.

24,501. I presume you took special precautions with regard to such gangs?—These were private people turned in by the owners of the houses to clean the houses.

24,502. There have been no bad results to persons so employed?—None yet.

24,503. How long have these gangs of coolies been doing this work?—I have only seen it done in one house.

24,504. How long ago was that?—With regard to the case imported from Ozar, the people were removed from their house; after about six weeks they applied for permission to re-occupy it. I gave them permission, but the house-owner and his family did not go to live in the house. He turned in coolies to clean the house. The house was being repaired when first evacuated, and the work which had been discontinued there was again proceeded with.

24,505. In this particular instance the case that occurred was imported, so that it is quite possible that the house was never infected, is it not?—It is quite possible.

24,506. Have you formed any opinion as to how the second infection took place?—I am of opinion that it was caused by the Kalals who go to the Ghoti Bazar, a badly infected village. I think they brought it from there. They are rice dealers, and deal largely in rice.

24,507. How far off is Ghoti?—About 20 miles, near Igatpuri.

24,508. Have you observed any cases of plague occurring during the second epidemic in houses in which it occurred in the first epidemic?—No, but I know as a fact that five have occurred.

24,509. In those five cases that have occurred, did they occur without the possibility of infection having come from outside?—I do not think it occurred from plague lying dormant in the house.

24,510. Has the great majority of cases which occurred during the second epidemic occurred in houses in which there were not cases in the first epidemic?—Out of 200 cases only five occurred in the houses which had been previously infected.

24,511. Have cases which occurred in the second epidemic occurred mainly in the same quarters as those in which they occurred in the first epidemic, or in

Lieut. A. N. Davidson, I.S.C.

8 March 1899.

different quarters?—In the same quarters. It is not my part of the city, but I know it is in the same quarter. It has not spread so rapidly into the town.

24,512. Have you noticed any mortality among rats?—No. I do not suppose I have seen 10 dead rats since I have been here.

24,513. Was there any mortality among rats before you came?—I heard of it.

24,514. You heard that there were dead rats in the first epidemic?—Yes, I heard of it. When I have gone round the city I have always looked for rats, and when I saw a dead one I made inquiries.

24,515. What system have you now got for preventing imported cases coming in without being detected?—The people have been warned, since we have started work in June, that they must report every case of arrival from infected places within six hours, and to the best of my belief we get the majority of these. When these cases are reported I see the new arrivals daily for 10 days. Out of, roughly, 8,000 people that passed through my hands from infected and uninfected places I have only had three imported cases of plague.

24,516. You mean you have seen 8,000 of these arrivals?—I have not seen 8,000, because out of that 8,000 5,000 or 6,000 would be from uninfected places. But out of 2,000 or 3,000 arrivals from infected places I have only had three imported cases of plague.

24,517. Do you find that the people are willing to help you to find cases of plague?—Yes.

24,518. Do you attribute that at all to the fact that they have already been previously harried by plague?—Yes. They are desirous of keeping people from the infected part of the city from going into the part we still believe to be uninfected.

24,519. Do you think they assist you more than they would in a town in which there had been no outbreak of plague?—Yes. I think they recognise that it is to their own good to keep it away from their houses.

24,520. Do you find that ordinary cases of death and sickness are reported here now?—Yes.

24,521. Do they report sickness?—Yes. I get reports of such things as children teething. I am speaking now about my part of the city. My opinions are not the same with regard to the Musalmans' end of the city.

24,522. (*The President.*) What is the quality of the houses in the quarters which you have spoken of as being chiefly infected?—The majority of the houses are dirty and dark.

24,523. That is in contrast with the general condition of the houses in this place?—I think the houses where plague chiefly is are especially dirty.

24,524. I suppose they are all pretty dark in the town?—The majority of the houses are dark, and there is no ventilation.

24,525. Was there any overcrowding, do you think, in these houses?—In some of them I think there was.

(Witness withdrew.)

Mr. G. W. Hatch, I.C.S.

Mr. G. W. Hatch, I.C.S., called and examined.

24,526. (*The President.*) You are the Assistant Collector of the Eastern Division of Khandesh?—Yes.

24,527. (*Mr. Cumine.*) I think your experience of plague is confined to the eastern part of Khandesh?—Yes, to the Jalgaon and Bhusawal talukas.

24,528. When did indigenous plague first appear in the Khandesh district?—In November 1897, in Jalgaon.

24,529. Is it known for certain where the infection came from?—There are two stories. One is that it came from Ghoti in the Nasik district, and the other that it came from Sholapur. In both cases Marwaris suffering from plague were supposed to have come and died at Jalgaon.

24,530. It came by human agency?—Yes.

24,531. After the discovery of the first suspected case, did you go and stay at Jalgaon, and watch all the deaths?—Yes, I went and stayed there and watched the deaths.

24,532. Did you mark down on a map* against the houses where they had occurred the deaths that had been occurring throughout the month of November?—Yes. All the deaths in November were marked on the map.

24,533. What is the special lesson that the map seems to teach? Does it seem to show that the noting of the localities where deaths are occurring is even more important than the noting their mere number, for purposes of seeing whether plague is in a town?—The map speaks for itself. There was an excessive mortality during the month of November, and 28 deaths occurred in *this* circle (*pointing on the map*). The average number of deaths for the month in previous years being 33, in November 1897 61 deaths occurred, and the excess (28) occurred in *this* small circle (*pointing on the map*).

24,534. (*The President.*) Plague deaths?—We did not know. By looking at the map one can see whether the deaths occurred in one locality. The probability is that they were due to plague.

24,535. (*Mr. Cumine.*) How many more villages became gradually infected in Khandesh?—Those I know about were Bholana and Pimpralla.

24,536. What was the total number in the Jalgaon taluka?—The total number was three in the Jalgaon taluka, and seven in the Jamner taluka.

24,537. Did the infection come from Jalgaon in those cases?—Yes.

24,538. There was one village became infected in the Amlaner taluka, I think?—Yes, and one in the Chalisgaon taluka.

24,539. Is it known where the infection came from in those two cases?—No, it is not known.

24,540. In what month did the 1897-98 epidemic cease in Khandesh?—In April 1898.

24,541. Did plague appear again this fair season in Khandesh?—Yes, it broke out in Kanaswadi, village within two miles of one of last year's plague-stricken villages—Bholana.

24,542. Will you give us an account of the outbreak in Kanaswadi?—Kanaswadi is a village of 269 inhabitants, almost entirely Kolis. It is distant about two miles from Bholana, and has little intercourse with other villages besides Bholana. The last case of plague at Bholana occurred on 18th March 1898. In November 1898, indigenous plague occurred at Kanaswadi. At that time there was no plague in Khandesh. There is no history of any case having been imported into Kanaswadi from outside the district, and I cannot consider that such a thing would have been possible. Examination of the death register at Kanaswadi, coupled with enquiry among the people, showed that the first death from plague had probably occurred on 1st October, and the second on the 2nd November. There were no deaths in the village between those dates. There was a story of a girl who had come from Bholana in August or September and who suffered from fever and a swollen face, but who recovered. Enquiries at Bholana showed that the village had been free from plague for the last five months. The accompanying extract from the death register shows this fact clearly enough.

Extract from Bholana Death Register
(from April to December 1898.)

Date.	Person.	Age.	Cause of Death assigned.
April 3rd	A Mahar woman,	25 years	Syphilis.
April 4th	A Dhangar child	1 year	——
June 25th	A Koli child	1 day	Bowel complaint.
July 10th	A carpenter	42 years	Paralysis.
July 12th	A Koli child	7 months	Bowel complaint.
August 2nd	A Koli youth	15 years	Bowel complaint.
September 23rd	A Kunali child	1½ month	Accident.
September 25th	A Koli child	1 year	Bowel complaint.
October 26th	A Vaidu child	1 year	Measles.
November 3rd	A Koli child	18 days	Bowel complaint.
December 4th	A Koli child	3 years	Bowel complaint.
December 6th	A Mahar girl	8 years	Fever.

* Not published with the Commission's proceedings.

† In the same house I discovered the girl with buboes on the 8th or 9th December.

However, on the 6th December, a girl had died at Bholana from fever, and in the same house on the 9th or 10th December I found another girl suffering from fever with buboes in the groin. The girl and her family were segregated; and she got well. No other person in Bholana fell ill during December. I took the census of the whole village several times in order to satisfy myself on this point. Nor has there been any outbreak at Bholana since. To my mind the only explanation of the outbreak at Kanaswadi is that the plague germ was imported from Bholana, that it existed at Bholana, throughout the rains, in a weakened form, and that it became virulent again when it got a fresh habitat at Kanaswadi.

24,543. I believe plague spread, this fair season, to several other villages in the Khandesh district. Do you remember how many, approximately?—I fancy some six or seven. It has come in fresh from Hyderabad.

24,544. Will you put in the figures with reference to the outbreaks with which you are best acquainted, viz., those at Jalgaon, Bholana, Pimpralla, Kanaswadi, and Gozora?—The table is as follows:—

Village.	Population.	Date of First Case.	Date of Last Case.	Total.	
				Cases.	Deaths.
Jalgaon - -	15,000	23 Nov. 1897	28 Feb. 1898 -	115*	102*
Bholana -	800	22 Jan. 1898	18 March 1898	30	23
Pimpralla -	3,100	27 Jan. 1898	19 March 1898	26	22
Kanaswadi -	269	1 Oct. 1898	8 Dec. 1898 -	25	21
Gozora - -	950	30 Nov. 1898	1 Feb. 1899 -	24	22

* To these figures should be added about 40 cases and deaths that occurred during October, November, and 1st week of December, *i.e.*, before there was any organization for discovering and recording cases.

24,545. With regard to evacuation, what are the lessons you think it teaches?—I have noticed three points: the first was, that partial evacuation is useless to stop the spread of plague unless it follows on the early detection of the first imported case. There have been several examples of that in the villages I have seen. In Jalgaon the evacuation of the quarter in which an excessive number of deaths had occurred was found to be useless. In the next few days cases occurred just outside the evacuated area, although we had left a considerable margin. At Bholana, when the village was evacuated, two families, in which were women about to be confined, were allowed to remain in the village. Their houses were distant from the infected quarter. Within the next ten days a case of plague occurred in each family. At Gozora a man died suddenly from fever on the 30th November. A fortnight later I heard that this man was a visitor from Kanaswadi (an infected village). I went to Gozora, disinfected the house in which the man died, and segregated the one person living in it. Fifteen days later, that is on 31st December, a death occurred in the next house; for the next five days a death occurred each day in neighbouring houses. On 7th January I went to Gozora and found a case of plague, Inquiries showed that the six deaths, from 31st December to 5th January, were all probably due to plague. It is noteworthy, that exactly one month elapsed between the death of the imported case and the first indigenous case. Between 30th November and 31st December only one death—of an old man from asthma—occurred in the village. On the other hand, I have seen many cases in which prompt evacuation of a few houses following on the discovery of the imported case has prevented the plague catching hold of the village. In all these cases the contacts were segregated and the houses disinfected within 48 hours of the death of the imported case.

24,546. I believe you have some charts which you wish to put in?—Yes.*

24,547. In the town of Jalgaon, I believe, plague was bad in November, and the town was evacuated at the beginning of December. When did the attacks finally cease?—The last case was on the 28th of February.

24,548. So that the plague took about three months to stop after evacuation?—Yes. We had only six cases throughout February.

24,549. You found that evacuation decreased the mortality?—Yes, it brought it down at once, as the charts* show.

24,550. (*The President.* Do the examples which you have mentioned of total evacuation apply to villages into which plague had only recently been imported?—In Jalgaon plague had been in the village for quite a month before evacuation.

24,551. Could you show us, from the Jalgaon chart,* what the effect of evacuation was?—There were two evacuations. We, at first, left in one-sixth of the town, but turned it out a month later. We left in one detached portion of the town. It did not seem necessary to touch it, as it was right away from the other part. Afterwards, however, we found deaths began to occur in the unevacuated portion, and we turned that out also.

24,552. (*Mr. Cumine.*) What is the population of Jalgaon?—15,000 roughly.

24,553. Is there a large trading community there?—Yes, it is the centre of the cotton trade.

24,554. When you turned all the people out, did you institute a system of passes, and put policemen upon the roads to attempt to prevent the people from leaving Jalgaon without permission?—Yes, that was done.

24,555. Was that successful?—I do not think it was; the people got away as much as they liked.

24,556. Did they carry infection to the other villages in their flight?—They carried it to the Jamner taluka. The place (Jalgaon) was too big to deal with properly; one could not keep an eye on 15,000 people in the fields camped all over the place.

24,557. What do you think is the size of a village you can evacuate so as to keep control upon the people, and stop plague within a few days, and prevent the people running away and infecting other districts?—I should say a village of not more than 2,000—a village where you can take a roll call every day and see that all the inhabitants are there.

24,558. Was taking a roll call found to be specially useful?—I have found it completely effective. Nobody ever ran away. In these other three villages of which I have charts*, Bholana, Kanaswadi and Gozora, I used to go round and take the roll call every morning; I never found a single man missing.

24,559. Were there any merchants or shopkeepers in those villages where the roll call system was successful?—There were a few, just one or two families.

24,560. Do you think, in the black soil of Khandesh, people could be turned out in the heavy rains without causing great hardship to them?—No, I do not think they could.

24,561. One chart* you have put in refers to the village of Bholana. How was it that plague did not stop immediately in that village?—In the case of Bholana the cases that occurred after the people had been out in the fields for a week were all traceable, either to contact with patients in the hospital, or to residence in the village subsequent to the general evacuation. There were two families allowed to stay in the village, and there were people who attended on their friends in the hospital. They were the only people who got plague there after the first week. At Kanaswadi there was not a single case after evacuation.

24,562. Will you describe the way in which you prevented the spread, to other places, of plague from infected villages?—In all the villages, except Jalgaon, a house to house census was taken at the time of evacuation. Subsequently, a daily roll call was called of all the people camped in the fields. No cordon or police guards were required. People knew their roll call would be taken, and they did not attempt to bolt. The result was most satisfactory. Neither Bholana, Pimpralla, Kanaswadi or Gozora became a fresh centre of infection. Bholana and Pimpralla were infected from Jalgaon. I have already given an account of the way in which Kanaswadi became infected. Gozora was infected from Kanaswadi before it became known that plague had broken out at the latter village.

24,563. Are there any particular points connected with the Jalgaon measures to which you wish to draw our attention?—Jalgaon is a large centre of the cotton

* *See* App. No. LXVII. (A) to (D) in this Volume.

Mr. G. W. Hatch, I.C.S.

8 March 1899.

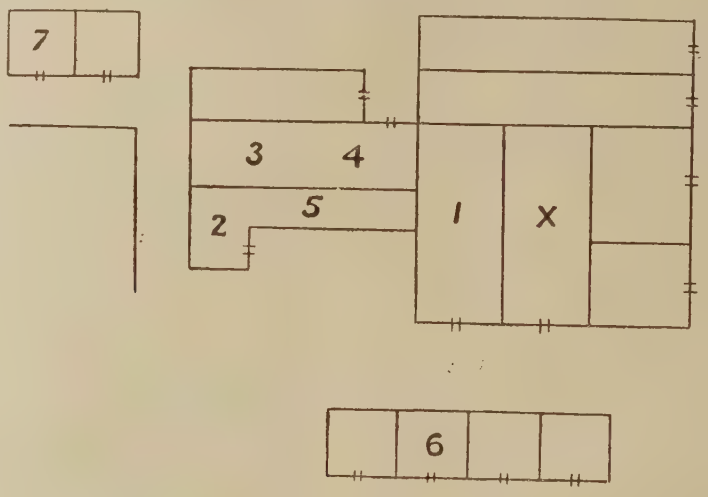
trade; it has a mill employing 1,000 hands and some 20 cotton cleaning and pressing factories. After the first panic on the discovery of the plague it was found possible to carry on the business of the town in spite of evacuation and plague restrictions. A bazar was set up in a field, and the cloth and grain merchants moved their goods and chattels out and opened their shops there and carried on their trade without much inconvenience. The mill put all their employés into camp at the first alarm of plague, with the result that not a single case occurred among them throughout the epidemic.

24,564. I think they had a special doctor for their employés, had they not?—Yes. One noticeable point about evacuation is that it costs nothing at all in these small villages. The people build their huts of karbi (*i.e.*, jowari straw).

24,565. Was there any striking example at Jalgaon of the way in which an influential native can get the people to go out if he leads the way?—Yes, we had several examples of that. It was all done by the influence of two or three native gentlemen.

24,566. When the Patel of the Kunbis went out, did not the whole population of Kunbis follow him?—Yes.

24,567. Do you put in a plan of the infected quarter of Gozora?—Yes, the plan of the infected quarter of Gozera, showing the order in which the deaths occurred, is as follows:—



× marks the house in which the visitor from Kanaswadi died suddenly of "fever" on 30th November 1898.

1 was a Koli girl, aged 5, who died on 31st December 1898.

2 was a Koli boy, aged 11, who died on 1st January 1899.

3 was a Sunar girl, aged 12, who died on 2nd January 1899.

4 was a Sunar woman, aged 41, who died on 3rd January 1899.

5 was a Koli, aged 40, who died on 4th January 1899.

6 was a Koli, aged 18, who died on 5th January 1899.

7 was a Koli girl that I found suffering from plague when I visited the village on 7th January.

24,568. You looked after some villages yourself, did you not?—Yes, Bholana, Gozora and Kanaswadi; I was there all the time.

24,569. What is the number of villages which, you think, one European can, personally, look after efficiently?—If he has to do all the superintendence himself he cannot possibly look after more than two or three, allowing two or three hours' work in each village.

24,570. (*The President.*) Have you adopted any system of disinfection in connection with your operations?—Yes. In all these villages, as soon as the evacuation was complete, the roofs of the houses were opened. In the small villages we took the roofs completely off. The houses were then disinfected with perchloride of mercury.

24,571. How long was it before the people were allowed to return to their houses?—We kept them out until the hot weather, about two months after the last case.

24,572. Have you any examples of any recurrence of plague in houses which had been so treated?—No, not after they were allowed to go back to the villages.

24,573. Are these villages now free from plague?—Yes, I have mentioned the case of Bholana. I found a case at Bholana this year, one case.

24,574. With the exception of that instance, they have all remained free?—With that exception, they have all remained free.

(Witness withdrew.)

(Adjourned till Monday, March 13th, at Bombay.)

At The Secretariat, Bombay.

Monday, 13th March 1899.

SIXTY-FOURTH DAY.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Prof. A. E. WRIGHT, M.D.
Mr. J. P. HEWETT.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. G. MULLANNAH, re-called and further examined.

Mr. G. Mullannah.
13 Mar. 1899.

24,575. (*The President.*) You, I think, have some information to give us in regard to experiments made on cotton* ?—Yes.

24,576. Will you be good enough to detail them?—I received six samples of cotton on the 22nd of January 1899.

24,577. Where did they come from?—They came from Kopbal.

24,578. Was there anything connected with plague in regard to this cotton?—The samples were supposed to have been taken from houses where plague cases occurred.

24,579. It occurred in each house?—Yes.

24,580. How long, before the cotton was taken from each house, had there been plague in the house?—I do not know that. I took a little bit of cotton from each of these four samples, and inoculated four broth tubes. Next day there was growth of a number of organisms in each tube. I examined the slide preparations from each, and among these four tubes I found one which contained polar staining bacilli. That cotton was from a place called Sampur. On the 23rd of January, therefore, I inoculated the rabbit with a half c.c. of this broth, in which polar stained bacilli were found. The rabbit died on the 25th; it was found dead in the morning about six o'clock when the laboratory was opened. At the *post-mortem* examination, we found that the inguinal and the axillary glands were enlarged, and that the lungs were congested. In the spleen, and in the lung, there were a few polar stained bacilli found, but the gland was full of polar stained bacilli. These polar stained bacilli were of different shapes; some looked like plague, but others were narrower and longer. I have a slide preparation of it here. (*Slide produced and handed in*). I made cultures from gland, blood, spleen, and lungs, but from the gland I had pure growth of cocco bacilli (yellow). From the lungs I got two different kinds of organisms, both polar stained, but one was motile, and the other not. Both, when grown in broth, made the broth cloudy, so I concluded that these organisms were not plague. I then inoculated two more rabbits with these.

24,581. From the original broth?—No, with the bacilli which were obtained from the lung. The rabbit which was inoculated with the culture of cocco bacillus did not die.

24,582. (*Dr. Ruffer.*) How much did you inoculate?—Two c.c. Four c.c. of broth was mixed thoroughly with the growth on one agar tube, and, out of that, two c.c. were used. I inoculated two rabbits, Nos. 154 and 155, with non-motile, and motile polar staining bacilli respectively. No. 154 was inoculated on the 4th with 2 c.c., and died on the 17th. The glands were not enlarged, there was no congestion of the lungs, and there were no signs of plague; it only died of septicæmia, and the polar staining bacilli were found in the blood and spleen. Rabbit No. 155 was inoculated on the 4th, and this died on the 12th, of septicæmia. In these animals neither of them had the glands enlarged, nor congestion of the lungs, but the polar stained bacilli were found in both of them. The rabbit inoculated with the cotton was suspicious. There were *post-mortem* signs of plague, but I could not get a growth of bacilli which I could call plague bacilli. The bacilli I cultivated from it were not plague. Probably there were more organisms in the cotton than these bacilli, and perhaps there might have been plague bacilli as well; but I could not give any definite conclusion about that, as I did not get a culture of plague from it.

24,583. The *post-mortem* appearances, and the morphological appearances, were those of plague?—Yes.

24,584. But the further tests did not confirm you in your opinion?—No, not in my opinion.

24,585. So that you can draw no accurate conclusion?—No, personally, I cannot.

24,586. On the whole, therefore, you have not succeeded in finding the bacillus in cotton?—No.

24,587. Are these all your observations in regard to cotton?—Yes.

24,588. You also made some experiments in order to test the prophylactic value of Haffkine's prophylactic fluid?—Yes.†

24,589. Would you kindly narrate these experiments, and the results of them generally?—Thirty rabbits were inoculated with contaminated Haffkine's fluid; out of these, 20 recovered.

24,590. (*Prof. Wright.*) What does contaminated mean? Artificially contaminated?—The fluid, as it is received from Bombay, was examined, and proved to contain septic organisms.

24,591. (*The President.*) A fluid in which you found living organisms?—Yes.

24,592. You did 30 experiments with the so-called contaminated Haffkine's fluid?—Thirty-eight; and 30 out of these were subsequently inoculated with plague, from which 20 recovered.

24,593. You first injected this prophylactic, and then there was a certain interval; what was the interval?—The interval varied; sometimes it was one week, and sometimes it was two months. In one instance there was more than two month's interval.

24,594. You then administered the plague virus by sub-cutaneous injection?—Yes, generally, but a few cases had a loop-full of pure culture of plague rubbed into a scratch made.

24,595. What was the general result?—Twenty recovered and 10 died. Among the 10, two died accidentally, and eight died of plague; besides these, from the protective itself, eight died.

24,596. What was the smallest dose of the protective administered in those eight experiments?—To those which had prophylactic alone, the smallest dose ad-

* *See* App. No. LXVIII. in this Volume.

† *See* App. No. LXIX. in this Volume.

Mr. G. Mullannah.

13 Mar. 1899.

ministered was 20 c.c. To those eight that died of plague the smallest dose administered was 1 c.c.

24,597. Twenty c.c., in a rabbit of average weight, appeared to kill the rabbit?—Yes, 20 c.c. in a rabbit of the weight of 1,500 grammes.

24,598. Twenty c.c. of protective in a rabbit invariably produced death?—No, in eight only of 38 cases.

24,599. Did you do any other experiments with the protective alone, except these eight? In all your experiments with contaminated protective fluid, did all the animals die?—Not all the animals; only those eight out of 38 cases.

24,600. The other 30 received both virus and protective. How many experiments were done with the protective alone?—Eight experiments were done with the prophylactic alone (if I am allowed to call them so). The eight animals, unfortunately, did not survive the effects of the prophylactic, to be further experimented upon with plague.

24,601. Therefore, all the experiments which you made with the protective alone, resulted in death?—All the 38 rabbits were inoculated with the contaminated protective fluid alone first; out of these, eight died from the effects of the protective. The remaining 30 survivors received subsequent inoculation of plague.

24,602. Now with regard to the re-sterilised fluid?—There were ten rabbits inoculated, and out of these, nine recovered after subsequent inoculation with plague. One died, and this one had a dose of one c.c. only.

24,603. What was the interval of time between the inoculation with Haffkine's fluid, and with the plague virus?—The rabbit, No. 140, for instance, had protective fluid on January the 19th, 1899, one c.c., one dose, and a second dose on January the 21st, 1899, two days afterwards, and it had plague on the 29th, eight days after the second dose.

24,604. Can you tell us what were the intervals of time between the inoculations?—From four days to about a week.

24,605. The interval between the last inoculation of Haffkine's fluid, and the administration of the plague virus, varied between what period of time?—It varied from four days to 14 days. None of the rabbits in this case died from the protective alone.

24,606. How many rabbits did you experiment with?—Ten.

24,607. In what doses?—In doses varying from one c.c. to 20 c.c.

24,608. Therefore, the 20 c.c. of the re-sterilised fluid did not produce death, whereas the 20 c.c. of the non-sterilised so-called contaminated fluid produced death?—Yes, in eight cases out of 38.

24,609. Can you tell us if the dose of virus which you administered was, so far as you were able to ascertain, near the minimum lethal dose, or much in excess of it?—One c.c. is about one and a half loop-full. Some rabbits recovered from one loop-full and some did not. Usually, with one c.c., every one used to die; that is the minimum lethal dose, I found.

24,610. What is the relation between one loop-full, and one c.c.?—One c.c. is equal to one and a half loop-full.

24,611. Therefore one half more than a loop-full was always fatal?—Yes.

24,612. With one loop-full they recovered sometimes?—Yes, but in these experiments, where only one loop-ful was used, the culture was rubbed into a scratch made, and one cannot say how much is really absorbed.

24,613. What experiments did you do with only one loop-full?—Experiments Nos. 72, 73, 74, 76, 77, and 79.

24,614. What was the interval of time between the inoculation of the protective and of the virus in these experiments; were they varying or all the same?—The same, about five days.

24,615. Five days in each case?—Yes.

24,616. And with an interval of five days between the two; what was the minimum quantity of Haffkine's fluid which appeared to save life?—Twenty c.c. was the only dose used in all these experiments.

24,617. Did you do any experiments on the same conditions with less than 20 c.c.?—No, not with one loop-full.

24,618. Twenty c.c. is, relatively speaking, a large quantity?—Yes.

24,619. Do you think very much less would have been successful?—I think so. There are three in the list. 153 with 12½ c.c. and 136 and 137 with 6¼ c.c. each.

24,620. Were there any serious symptoms in those experiments in which 20 c.c. were employed and the animals recovered? Did the animals suffer badly?—The symptoms were serious; the temperature was very high.

24,621. Was there any other serious symptom other than the temperature?—Yes, local symptoms, abscesses, and ulcers.

24,622. Was the animal very ill?—Yes.

24,623. Was it lethargic; was there any paralysis?—There was no paralysis.

24,624. Did it eat its food?—No, it became very weak and reduced in weight, and laid about.

24,625. Therefore 20 c.c. was a great deal too much in excess of the quantity required?—Yes, we found 2 c.c. protected in one case, No. 162, but the fluid was more or less pure, not nearly so contaminated as that of earlier date.

24,626. What experiment did you do with 2 c.c., where the conditions were the same?—Experiments No. 161, 162, 163, and 164.

24,627. What were the conditions of those experiments?—These rabbits were inoculated with 2 c.c. of more or less pure fluid, only one dose, and then after about nine days they were inoculated with one c.c. of plague, and all of them recovered.

24,628. Have you used a smaller quantity?—Yes, we used one c.c., and the animal died.

24,629. Anything between one c.c. and two c.c. is sufficient to prevent death?—I do not know; we have no experiments on this point.

24,630. Assuming that in a rabbit two c.c. is the quantity required, how much would be required for a man, also assuming that the effect is equal in both cases?—About 90 c.c., according to weight, if the power of different constitutions be not taken into consideration.

24,631. Have you any experiments that seem to indicate the duration of the protection?—We have here one experiment to show that the protection lasted for two months.

24,632. What were the conditions of that experiment?—Rabbit No. 71 was inoculated with 20 c.c. on the 19th of November 1898, and it was inoculated with plague on the 21st January 1899.

24,633. What was the interval?—Two months and two days.

24,634. What was the dose of virus?—One c.c.

24,635. The quantity of protective that you found necessary was ten times greater than when the interval was nine days?—Yes, but less fluid might have had the same duration of protection, but we have no experiments on this point.

24,636. Supposing 20 c.c. is required to produce protection for a period of two months in a rabbit, how much would be required for a man?—Ten times 90.

24,637. Have you any experiments that show that less than 20 c.c. would produce protection for less that two months?—No.

24,638. Have you any experiments, to show protection in one month?—No. We have not done any experiments to find out that a certain amount of fluid has a definite duration of protection.

24,639. Have you any experiments excepting the one you have referred to, which indicate the time for which any given quantity will produce protection? In this instance you have an experiment showing protection for two months. Have you any experiments which show protection for either a longer or a shorter time than two months?—There are many of shorter.

24,640. How much shorter; what interval of time?—Only a week or two.

24,641. They were only a week and two months?—The duration varies from five days to two months and few days. No. 111 had a duration of 24 days.

24,642. In what condition was the Haffkine's fluid when you first used to obtain it?—All contaminated.

24,643. Contaminated with what? — With living organisms.

24,644. Organisms of putrefaction?—Yes.

24,645. Did you find that any improvement took place latterly?—Yes.

24,646. In what respect?—Latterly, there were no organisms in some, and others were much purer.

24,647. Was it absolutely pure latterly? — Some bottles were absolutely pure.

24,648. Not all were absolutely pure?—No, not all.

24,649. What effects did you observe from this impure fluid?—Abscesses, ulcers, septic intoxication, and the reactionary fever.

24,650. Did you get death in any instance?—Yes, in eight cases out of thirty-eight, before referred to.

24,651. What kind of symptons?—Toxic.

24,652. Not suggestive of plague toxæmia?—No, septic toxæmia or intoxication.

24,653. What was suggestive in the reactionary fever?—Plague toxines.

24,654. I understand that you yourself, finding that you had living organisms, took some measures to get rid of them?—Yes, under the orders of the Plague Commissioner.

24,655. What did you do?—I heated the fluid for three consecutive days, for a quarter of an hour, at 60 degrees Centigrade.

24,656. What was the result of that treatment?—The fluid became sterile.

24,657. There were no longer any living organisms?—No.

24,658. Did you make experiments at the same time with this fluid alone?—Yes.

24,659. What kind of symptoms did you obtain with it?—We never had abscesses or ulcers, and always had a temperature lower than with the contaminated fluid.

24,660. A lower temperature and no local symptoms?—No local symptoms and no deaths too.

24,661. What was the maximum dose which you injected of the re-sterilised fluid?—Twenty c.c.

24,662. That, again, was a dose which, you have already stated, was generally fatal with the contaminated fluid?—Contaminated fluid was fatal in eight cases out of 38.

24,663. You found that it was not so toxic; what did you find in regard to it protective power?—It had a protective power.

24,664. In an equal or in a less degree?—In one case it was more powerful, because the same dose killed the rabbit in the case of unsterilised. In the sterilised, it saved the animal under equal conditions.

24,665. Was there any increase in protective power?—Certainly in one case, No. 122, compared with 128.

24,666. (*Dr. Ruffer.*) You say in Clause A of your Memorandum* that you inoculated with plague animals protected with re-sterilised Haffkine's fluid, and that nine recovered. Did you inoculate control animals of the same weight at the same time?—Yes.

24,667. What happened to the animals?—The controls died.

24,668. In each case?—Yes.

24,669. After how long;—After three or four days.

24,670. To re-sterilise the fluid, you say you heated it to sixty degrees Centigrade for a quarter of an hour for three consecutive days. How did you ascertain the temperature of the fluid when you heated it?—With a thermometer.

24,671. Where did you put the thermometer?—In the water surrounding the fluid.

24,672. How did you know that the inside of the bottle had reached 60 degrees? It takes some time for the heat to penetrate through the bottle to the fluid inside?—A few minutes were allowed for the heat to penetrate through the bottle to the fluid inside before we began to reckon the required time.

24,673. How long did you keep the bottle in the water?—For a quarter of an hour.

24,674. You think that sterilised it?—Yes. It did sterilise it.

24,675. Did you make any experiments to find out if it was sterilised?—Yes, by inoculating agar tubes with the fluid and no growth occurred in them.

24,676. How much fluid did you take?—Twenty or thirty drops.

24,677. In Class B of your Memorandum,* when did you look for contaminations? Did you look for them at the time you inoculated the fluid into the animals, or some time before?—In some cases it was done before, in others afterwards, whenever we wanted to examine any fluid, but, generally, at the time of inoculation, when the bottles were opened for inoculating purposes, the agar tubes were inoculated with the fluid.

24,678. You think that is a good method?—Yes.

24,679. You say in your remarks*:—"As received by "us originally, Haffkine's fluid was, without exception, "contaminated with organisms of putrefaction"?—Yes.

24,680. How many bottles of Haffkine's fluid did you get originally?—I cannot say the exact numbers off-hand, but it was more than 20 dozen.

24,681. Did you make a bacteriological examination of each one of them?—Of each one used in the experiments.

24,682. You say you did not examine every bottle. I want to know how, then, you can say that "without exception" they were all contaminated? — Generally one bottle from each brew was examined, other times two or more from each brew.

24,683. How can you say they were contaminated without exception, if you have not examined every one?—We examined one bottle from each brew.

24,684. You say it was contaminated, without exception, and I want to know how you can say that if you did not examine each bottle?—It means every on without exception, of those that were examined.

24,685. In your statement* you say "When employed "by inoculation in rabbits, animals which are pecu-"liarly resistent to ordinary septic processes." Can you tell me on what evidence you base that statement?—Rabbits are supposed to be immune from septic organisms.

24,686. Why?—It is a generally accepted opinion of scientific men. Our first series of experiments (control) prove it; besides, I have inoculated some rabbits, and have seen them immune; they do not die, they get abscesses, and recover afterwards.

24,687. From what organisms? — Staphylococcus pyogenes aureus and albus.

24,688. How much do you inoculate?—Twenty c.c. of pyogenic cocci in broth.

24,689. Did you inoculate the same quantities in other animals than rabbits?—No.

24,690. How can you say they are peculiarly resistant if you made no comparative experiment; on what do you base that statement?—I know, for certain, that if 20 c.c. of pyogenic cocci be inoculated into a rat, it is quite sure to die. So I did not think it is worth while to do such an experiment.

24,691. How much does a rat weigh?—I do not know.

24,692. A rat would weigh about 200 grammes at most, and a rabbit possibly ten times as much. What do you think reactionary fever is due to?—The toxines of plague.

24,693. Then you do not think it is due to plague itself?—No.

24,694. Did you ever find the plague bacillus in any animal inoculated with the prophylactic alone?—Yes, once.

24,695. Did you find plague bacillus in that animal?—Yes.

24,696. How did you ascertain that the animal died of plague?—From *post-mortem* appearances of plague, and the organisms isolated from that animal proved to

* *See* App. No. LXIX. in this Volume.

Mr. G. Mullannah.

13 Mar. 1899

be plague bacilli when further tests were applied to them.

24,697. How long after the inoculation did the animal die?—The rabbit, No. 96, was inoculated on the 14th December, and died on the 20th; it died six days after inoculation.

24,698. Were you experimenting with plague bacilli in your laboratory at that time? Were there any other experiments going on with plague in the laboratory during that week?—No, not at that time nor a week following.

24,699. There had been, surely. I see you inoculated an animal on the 1st of January, and also one on the 12th of December?—The 1st of January is more than two weeks from that date.

24,700. I see you inoculated five animals on the 12th of December?—Yes.

24,701. Was that animal anywhere near the other animals?—No, it was in a separate cage.

24,702. It was in the same room?—Yes.

24,703. Is it possible that it might have been infected from another animal?—No, it was in a separate cage. There were a good many rabbits, and others must have died of plague also.

24,704. A good many did die?—Only those inoculated with plague died of plague.

24,705. You state that one of these animals died of enteritis, in experiment No. 72?—Yes.

24,706. Did you find the plague bacillus in that animal?—No.

24,707. No. 73 died of tetanus; did you find any plague bacilli in that animal?—No.

24,708. Then these animals should be excluded?—Yes.

24,709. Then how did they die of enteritis and tetanus after being inoculated with plague?—The above experiments refer to those animals which had a loop-full of pure plague culture rubbed into the scratch made, and they had open sores.

24,710. How does an animal get tetanus unless you put it into it?—It can catch it naturally, from the cage or from the grass or dust in the cage, without the virus being put into it by somebody.

24,711. Where was the animal inoculated?—In the thigh.

24,712. Where did the symptoms begin?—In the leg.

24,713. That looks as if it came from inoculation?—Not at all, if it came from inoculation it would affect the other animals too.

24,714. It looks like it?—I do not see how it does. The other rabbits would have got tetanus as they were inoculated on the same day and at the same time.

24,715. What animals were inoculated on the same day?—Nos. 72, 73, 74, 76, 77, and 79.

24,716. No. 75 died of toxæmia. What do you mean by toxæmia in that case: what were the symptoms?—There were no organisms to be found in any organ; and we made cultures, and did not get any growth.

24,717. That is a negative thing; what were the positive symptoms you noticed?—Nothing special, except that it was inoculated with toxines of plague.

24,718. On what clinical symptoms did you base your diagnosis of toxæmia? If you make a diagnosis you must have based it on some phenomena observed; what were the phenomena?—The animal was inoculated with toxine, and there were no organisms. The cause of death was not found out. As the result of inoculation the animal became very ill, had a very high temperature, and then died.

24,719. (*Prof. Wright.*) You said one rabbit died of plague after inoculation with Haffkine's prophylactic?—Yes.

24,720. How many cages have you for rabbits in your laboratory?—About 26 or 27.

24,721. Do you think that a rabbit has died of plague in every one of those cages?—No.

24,722. Was it an absolutely new cage?—No, it was a burnt cage. If the animal dies in a cage we burn the cage, and afterwards the same cage is used for fresh rabbits. We have all iron cages, and we put them in the fire and heat them when required, and they are then used again.

24,723. The rabbit was put into a cage of that kind?—Yes.

24,724. I suppose it was in a cage on the floor beside other cages?—Yes; it was raised above the floor. We generally keep the cages on rows of bricks, and so they are raised above the floor.

24,725. Are there other rabbits also on that platform?—Yes, on the same level, but not on continuous platform.

24,726. Can the urine from one rabbit fall into another cage?—No.

24,727. Why not?—It would fall on the ground; it cannot get into another cage. All cages are apart from one another, separated with little spaces. The floor of one cage is not continuous with the other.

24,728. Have any rabbits died from accidental causes in your laboratory?—Yes, some that had open sores died of tetanus.

24,729. You have, every now and then, deaths among your animals in the laboratory, have not you—among the animals that you have not been experimenting upon?—There was only one rabbit that died in that way, and that died, as I have said before, of tetanus.

24,730. You have often other accidental deaths, have not you? It is a common thing in a laboratory to have accidental deaths among the rabbits that you keep in stock?—There are only two here; one died of enteritis and one of tetanus.

24,731. Is it not a common thing, in your opinion, for rabbits to die accidentally—the rabbits that have not been experimented upon?—We had only two cases of such deaths.

24,732. In what period?—Over a period of ten months.

24,733. What do you infer from the fact that that rabbit died; do you infer that there were plague bacilli in that particular bottle?—Yes.

24,734. Had you tested that particular bottle?—It was tested here in this way, by inoculation.

24,735. You did not test it microscopically?—Yes, I did.

24,736. Did you find any organisms?—No. Nothing besides cocci and a few slender bacilli.

24,737. You still believe that the bottle contained plague organisms?—Yes.

24,738. Why?—Because it is not always possible to find them with microscopical examination alone.

24,739. Have you any record of that particular bottle; in your list you have the entry "Contaminated"? Would you tell us what you found in that case?—The organisms isolated from that particular bottle were staphylococcus pyogenes aureus and albus and long slender, non-motile and non-pathogenic bacilli.

24,740. Those you found in that bottle?—Yes.

24,741. How did you find out it was plague? After that rabbit died did you get cultures?—Yes.

24,742. Were they pure cultures of plague?—Yes.

24,743. Were there no other organisms?—No.

24,744. How did you know it to be a pure culture of plague; did you inoculate other animals with it?—Yes.

24,745. Did you get a cultural test?—Yes, and I also inoculated pigeons and fowls.

24,746. Why?—Because it might have been mistaken for fowl cholera, and I inoculated the fowls to see whether fowls could be inoculated with this.

24,747. What control animals did you have for these various experiments?—Healthy rabbits.

24,748. Did you use a control every time you inoculated a series of animals?—Generally one control rabbit; but sometimes we had six.

24,749. Why are these controls not entered on your list?—It is not entered in this list, which was simply a list of particular experiments put together for the information of the Commission; it is entered in the usual records which I have with me now.

24,750. You say that every one of the controls died throughout the whole of your experiments?—Yes, except those inoculated with a loop-full; among those, two controls recovered.

24,751. Why are these controls not entered on your list; is it simply an accidental omission?—They are not entered.

24,752. Did you, in every case, find that heating to 60 degrees three times effectually sterilised the fluid?—Yes, in every case.

24,753. (*The President.*) You have one rabbit in your experiments in which the conditions produced were very suggestive of plague?—Yes.

24,754. Buboes were produced by the culture of the cotton?—Yes.

24,755. Where was the inoculation performed?—In the thigh.

24,756. In the right or left, or both?—We generally do it on the left.

24,757. Do you know where the buboes were in that case?—In both the groins, and in both axillæ.

24,758. Was there any time succession in the appearance of these buboes, or did they appear simultaneously?—I cannot say, as it is not possible even to feel them during life.

24,759. In regard to some questions you were asked in reference to re-sterilization, you have subjected your fluid to a temperature of 60 degrees for a quarter of an hour, three times?—Yes.

24,760. I understand the fluid was contained in a flask, which was plunged into water, the temperature of which you ascertained?—Haffkine's bottles were heated in a metallic vessel containing water.

24,761. How large was that vessel; what was the capacity of it?—Just large enough to hold about ten bottles of Haffkine's fluid.

24,762. What do you mean by the toxines of plague, as distinguished from plague itself?—One is the product of the other. When you say plague, it may mean bacilli; an animal dying from plague bacilli will be a source of infection.

24,763. Plague bacilli, plus toxines?—Yes.

24,764. They are both plague—the toxines as much as the bacilli?—Yes, but the one being a chemical substance can never be infectious, whereas the other, being living, is always infectious.

24,765. (*Prof. Wright.*) Did you choose the six bottles of prophylactic, sent to me, at Calcutta, for testing purposes?—Yes.

24,766. Were those fair samples of the bottles which you had?—Yes.

24,767. You have spoken of two kinds of bottles; you had one earlier series, which were found very contaminated, and one later series, which you found less contaminated?—Yes.

24,768. Were the bottles which you sent to Calcutta taken from the earlier series?—Yes.

24,769. Were all the bottles which you used in your experiments contaminated?—Yes.

24,770. What about the later series of bottles; did you get them after the Commission had left Hyderabad?—Yes, after the Commission had left.

24,771. Did you get a series of different brews then?—We received bottles of different brews on two occasions.

24,772. You found those a great deal less contaminated?—Yes.

24,773. Did you find any of them contaminated?—Yes, some; but less contaminated. One day I examined six bottles; three were contaminated, and three were not contaminated.

24,774. (*The President.*) Do you think that plague has varying degrees of infectiveness?—Yes.

24,775. In the statement of experiments handed in,* it is stated that "Plague is a disease which shows "itself in many forms. In its virulent forms it is "highly infectious, in its mild aspects it is hardly "infectious at all. To make inoculation universally "acceptable what is now wanted is that Haffkine's "fluid shall be made of uniform strength, so that with "a minimum dose the re-actionary fever shall be of "known intensity and protective power, and not under "any circumstances contagious." Have you any evidence in support of the statement that plague is not contagious in some form?—I think every form is contagious.

24,776. Who wrote this statement about plague?—Dr. Lawrie.

24,777. Do you adhere to it?—No, I do not adhere to that.

24,778. Why did you sign it?—It is mentioned, in brackets, that I do not agree with it.

24,779. That refers to a different point from what I have examined you upon. It is a question of contagiousness. I understand you do not adhere to it?—No, I do not adhere to it.

24,780. (*Prof. Wright.*) Did you do all these experiments yourself?—Yes.

24,781. Did Dr. Lawrie take any part in the experimental work?—No he simply ordered me to do it, and supervised it and verified all the results.

24,782. And then he wrote the report?—Yes.

24,783. (*The President.*) Look at experiments Nos. 166 to 173. Are these experiments in which 2 c.c. of the sterilized fluid were injected?—In half of them it was re-sterilized fluid, and in the other half more or less pure.

24,784. When was plague inoculated?—Eleven days afterwards.

24,785. What has been the general results of these experiments?—I do not know the results.

24,786. You have just heard by telegram that Nos. 166 to 173 are all alive?—Yes.

24,787. Therefore, in each case, the 2 c.c. has been successful?—Yes.

24,788. What was the dose of the virus?—One cubic centimetre.

24,789. Do you know of any control experiments made before this series?—Yes.

24,790. The telegram says that they are all dead?—Yes.

24,791. Then there is experiment No. 112. Kindly look at that. How does this differ from the series we have now been speaking about?—In the amount of the dose, and the period of time.

24,792. Is the dose larger or smaller?—Ten times larger.

24,793. The dose of what?—Of Haffkine's contaminated fluid.

24,794. Is there any other difference?—The time.

24,795. What is the difference in time?—No. 112 was inoculated with Haffkine's fluid on the 28th of December 1898.

24,796. It is the interval of time I want to know. What is the interval of time between the two?—Two months and 12 days.

24,797. What was the interval of time in the case of the other experiments?—11 days.

24,798. Was the dose of virus the same?—Yes.

24,799. The result, in experiment No. 112, is that the animal died, but that experiment is in no way comparable with the others in so far as the interval of time was, relatively, an enormous one?—That is so.

24,800. Let us take another experiment, No. 104. I see the doses are the same; was the interval of time the same as in No. 112?—The interval was two months and 24 days.

24,801. That animal died also?—(Note added by witness on correcting proof of his evidence:—It was alive before I left Hyderabad, and now I see it is still alive.)

24,802. It is not at all comparable; it only shows that 20 c.c. was insufficient when the time is so protracted?—That is so.

24,803. (*Dr. Ruffer.*) We found, in examining the proof of your evidence which you sent back, that you had added several things to your evidence?—Yes.

24,804. The Commission was of opinion that this could not be allowed, but that if you wished to make any additions now to your former evidence you could do so. Perhaps you will kindly state what additions you intend to make. I find that in Question No. 5221 I asked you, "You made a *post-mortem* examination, what did you find"? and your answer was, "Germs

* *See* App. No. LXIX. in this Volume.

Mr. G. Mullannah.

13 Mar. 1899.

were found in the blood, spleen and glands." Do you wish to add anything to that?—*Post mortem* signs of plague. The glands were enlarged.

24,805. Anything else?—Hæmorrhagic. Plague germs were found in the blood, spleen, and glands. It died of septicæmia.

24,806. Is that all you wish to say?—Yes.

24,807. At Question No. 5231 I asked you, "Did you grow the microbes in gelatine"? and you answered, "No." At Question No. 5233 I said, "You have no knowledge of how it grows in gelatine"? and you replied, "Yes, I have." Then I asked, "How does it grow"? and you replied, "It does not liquefy the gelatine," and so on. The two things are contradictory?—I thought you asked whether I had grown plague gems in gelatine, so I stated accordingly. I have grown plague germs in gelatine in Berlin, but not in India. There is, therefore, nothing contradictory in these two things.

24,808. So that the second answer refers to the Hyderabad plague microbe. You say you have no knowledge that it grows in gelatine. "It" refers to the microbe you isolated in Hyderabad?—To your Question No. 5231, "Did you grow the microbes in gelatine"? my reply was, "No." To your Question No. 5233, "Do you know how the plague germs grow in gelatine"? I replied, "Yes, I have, but not here." Here I had not mentioned the name of the place (Berlin) where I did grow plague germs in gelatine.

24,809. But you do not know how the Hyderabad microbe grows in gelatine?—No. I have not cultivated plague germs isolated in Hyderabad on gelatine on account of heat.

24,810. Then at Question No. 5247 I ask you, "What "is the morphological difference between the bacillus "you found and these other bacilli, the bacillus of "fowl cholera, for instance?" and your reply was, "They resemble one another." Is there anything you wish to add to that?—There is little or no morphological difference under the microscope.

24,811. I said, "What is the morphological difference "between the bacillus found and these other bacilli, "the bacillus of fowl cholera, for instance?" and you answered, "They resemble one another"?—They resemble one another except in the involution forms. If you find peculiar characteristic involution forms of plague there is a difference.

24,812. I asked, "What is the morphological dif-"ference between the bacillus found and those other "bacilli, the bacillus of fowl cholera, for instance." Your answer was, "They resemble one another." Do you wish to add anything to that answer?—Yes. It differs in the involution forms. The plague has particular involution forms.

24,813. You are referring here to the bacillus which you found in the earth?—Yes, that has the same peculiar involution forms as the plague germs of Bombay.

24,814. In answer to my Question No. 5252, you simply say, "By Gram solution." Is there anything else you wish to add to that?—By means of Gram's solution, its characteristic growth in broth, and in broth and ghee, its invisible growth on potato, characteristic involution forms, its very, very feeble or non-motility, and the effects of inoculation on different animals.

24,815. Then, in Question No. 5260 I say, "How is this a 'control experiment' of No. 1"? Is there anything you wish to add to your answer?—The word "control" is really wrong; it is not scientific. These experiments were done only to the mere suggestions; they were controlled to the suggestions made by Dr. Lawrie and others as to the effects on rabbits of septic or other fluids.

24,816. At Question No. 5266 I ask you, "How can 'sterile pus' be described as a 'putrid substance'"? and your answer is, "Our object was simply to note "the effects of inoculation of pus directly from a liver "abscess." Do you wish to add anything to that?—Sterile pus was never described as a putrid substance. I received pus from a liver abscess, but I did not know if the pus contained organisms or not. I found afterwards that there were no organisms in it, so it was put as "sterile pus." The object of inoculation was only for various suggestions, whether you get septicæmia from these substances, and then to see the difference between the bacillus which produces septicæmia, and the bacillus of plague.

24,817. The same addition would do for Questions Nos. 5269 and 5270?—Yes. They were all "control experiments" in that sense.

24,818. Then, at Question No. 5283, I ask you, "Why is your bacillus not the pneumo-coccus"? and you answer, "There are great differences. First of all, the mor-"phology; the pneumo-coccus is a large bacillus. "One can see it at once." Do you wish to add anything to that?—The shape and size of the pneumo-coccus, its capsule, its growth in different media, and the effects of inoculation into different animals.

24,819. At the last I see I gave it up, and I said, "I give it up. I cannot find who is responsible for it." At the time you made no answer to the question?—I have already given the answer before, that I am not responsible for the statement, but I am only responsible for the experiments.

24,820. (*Prof. Wright.*) We have before us a letter from Colonel Lawrie with regard to the finding of plague in cotton.* Did you make the experiments upon which that letter was based?—It referred to the experiments I made.

24,821. Will you please answer my question in the form I put it; did you make the experiments upon which that letter was based? We have a letter from Colonel Lawrie stating that the plague bacillus was found in a sample of cotton sent in for examination by Mr. Stevens. Did you make the experiments upon which that statement was based?—Yes.

24,822. Did anybody else assist you in making these experiments?—No.

24,823. Colonel Lawrie's report is based exclusively upon your experience on this subject?—Yes, but he himself also examined the animals, caltures, and preparations.

24,824. I see you say that the samples were received on the 22nd instant; how many samples were there?—Six.

24,825. Then you say, "Cultures were made in broth from these samples on that day"?—Yes.

24,826. "On the 23rd the broth cultures became cloudy and contained growths"?—Yes.

24,827. Does that mean that you inoculated six broth tubes and all were cloudy?—No; I took only four out of the six samples. I inoculated four broth tubes. The next day we found organisms in all; but one tube contained polar staining bacilli.

24,828. You received six samples, and your experiments were carried out with four?—Yes, on that date.

24,829. In the case of each of these four samples you inoculated one tube of broth?—Yes.

24,830. How were these samples of cotton introduced into the broth; were they received in a bottle?—No; they were in parcels; in envelopes.

24,831. Then there were no precautions taken in shutting them up inside those envelopes?—These envelopes were shut up in a tin case.

24,832. What happened? Did you tear open the envelopes?—Yes, with bacteriological precautions.

24,833. Then you put a piece of cotton into a tube?—Yes.

24,834. And the next day you found all four tubes contained organisms; all were cloudy?—Yes.

24,835. Did you examine the contents of each of these tubes?—Yes.

24,836. And in one you found polar stained bacilli?—Yes.

24,837. You paid no attention to the other three samples?—No.

24,838. You proceeded to inoculate that one?—Yes.

24,839. What happened?—The rabbit had a temperature of 104° and afterwards 105°.

24,840. At 2 p.m. that day three rabbits were inoculated with ½, 1, and 2 c.c. respectively, of broth culture; is that so?—Yes.

24,841. You inoculated three rabbits?—Yes.

---

* *See* App. No. LXVIII. in this Volume.

24,842. These rabbits were not new rabbits; they were rabbits which had been previously used, were they not?—Yes.

24,843. Why did you choose rabbits that had been used for previous experiments?—We had no other rabbits; we had no supply of rabbits.

24,844. Therefore, you had to take rabbits which had been previously used for experiments with Haffkine's prophylactic. It says here, that, at 2 o'clock on the 23rd instant, three rabbits, which had been inoculated with culture organisms found in Haffkine's fluid, were taken; those were inoculated?—Yes.

24,845. You did not use new rabbits, because you had no new rabbits?—The rabbits used were not inoculated with Haffkine's fluid itself, but with the organisms isolated from it, and which produced no effects.

24,846. Did one of these rabbits die?—Yes, No. 143.

24,847. It says here that these rabbits were inoculated with ½, 1, and 2 c.c.'s respectively?—Yes.

24,848. The temperature of the first rabbit rose to 105°?—Yes.

24,849. That was the rabbit that had ½ c.c.?—Yes.

24,850. What happened to the rabbits that had 1 c.c., and 2 c.c.?—There was no rise of temperature and they did not die.

24,851. There was no rise in the temperature?—No.

24,852. Supposing you have plague bacillus in a culture, and you give one rabbit ½ c.c., another 1 c.c., and another 2 c.c., which rabbit would you expect to get a high temperature, the one that received the small dose of plague or the one which received the large dose of plague?—One expects higher temperature in an animal which had a larger dose. But the facts here were not so.

24,853. When you made a *post mortem* of the rabbit that had the small dose, you came to the conclusion that it had died of plague?—*Post mortem* appearances were like plague. The glands were enlarged, and there was congestion of the lungs.

24,854. Taking the glands first, have you not constantly found that when you inoculate rabbits with any septic micro-organisms they get enlarged glands?—Only one gland, near the seat of inoculation; I never found all the glands of the body enlarged.

24,855. How large were these glands all over the body?—They were six or eight times the normal size.

24,856. How large altogether, the size of a lentil?—Yes.

24,857. Would that, of itself, have led you to suspect that the rabbit died of plague?—No, there was the condition of the lungs.

24,858. What did you find in the lungs?—There was congestion of the lungs.

24,859. Have you found congestion of the lungs only in plague?—In other diseases too.

24,860. Did the *post mortem* give you any reason to suppose that this was plague?—The organisms resembled plague.

24,861. That is another matter. Apart from microscopic observation, would you have been able to tell that that rabbit died of plague?—Those two characteristic signs were very suggestive of it.

24,862. Those seemed so strong that you think the rabbit died of plague?—Yes, I thought so.

24,863. You have never seen those independently?—I have never seen all these signs together.

24,864. Then you examined under the microscope and found bacteria which you took to be plague?—Yes, they looked like plague bacilli.

24,865. What did you stain them with?—With gentian violet.

24,866. You found bi-polar staining?—Yes.

24,867. Did you come to the conclusion that they were plague bacilli?—I wanted to get a culture of those organisms, and then to see whether they behave like plague or respond to similar tests.

24,868. Did you communicate the fact that you had found this to Dr. Lawrie?—I told him I had found bacilli like plague.

24,869. And did Dr. Lawrie say that they were plague bacilli?—Yes.

24,870. Did he inform the Government that plague bacilli were found?—I think so.

24,871. Were you a party to that; are you responsible for it?—I am not responsible for it, and I was not a party to it.

24,872. Did you authorise Dr. Lawrie to state that?—Dr. Lawrie made the statement on his own authority. I asked him to wait for a few days in order that I, myself, might be sure whether it was plague or not.

24,873. You were not willing to say straight off that those bacilli were plague?—No.

24,874. When you further investigated the matter, did these bacteria turn out to be plague bacilli?—No, not in my opinion, but in Dr. Lawrie's opinion they were.

24,875. You were satisfied that they were not plague bacilli?—Yes, the organisms isolated were not plague.

24,876. You think the report was really based upon insufficient evidence?—Yes, I think so, but Dr. Lawrie does not.

24,877. And your opinion, now, is that there was no plague in the cotton?—I cannot give any definite opinion about that. I could not get any plague germs separated.

24,878. Inasmuch as only the rabbit that got the least of this germ died, do you think it is probable that there was plague in this cotton?—I think it is probable that it contained plague germs.

24,879. You said a minute ago that the germs you found were not plague?—I said the germs isolated were not plague. But it is also possible that there might have been plague germs which I could not isolate on account of rapid growth of other organisms.

24,880. There may be plague germs anywhere, but have you any reason to suppose there were plague germs there?—In that particular case *post mortem* appearances were very suggestive of them.

24,881. You had no reason, from microscopical examination, to conclude these were plague germs then?—No; I inoculated two more rabbits with these organisms which I separated, but they did not produce the same symptoms, *i.e*, the enlargement of the glands and congestion of the lungs. Hence it shows that the organisms which produced these changes were not isolated.

24,882. Your conclusion is, that you did not get plague bacilli out of those rabbits?—Yes, from that rabbit.

24,883. You do not think there is any experimental evidence to show that cotton does carry infection?—There is no experimental evidence.

24,884. Do you not think that, if the bacteria which you grew had been plague, you might have expected to find the other two rabbits dead which received larger quantities?—Yes, but in a broth tube you generally get clumps of bacteria clinging on to one place, and it is possible also that you might get all the bacilli of one kind in half a cubic centimètre. You will always find in a broth tube that the organisms are not distributed evenly.

24,885. Where are the bacteria distributed in a broth tube, at the top or bottom?—The bottom generally.

24,886. It was the first rabbit that got the stuff from the top which died, while the one that got the stuff from the bottom survived. If it had been well mixed up they would all have had an equal quantity of plague?—Even if you shook the tube well up, I do not think it would be possible to distribute all the organisms evenly, unless the shaking up is kept up for some time.

24,887. Was the control experiment made with ordinary cotton?—Yes.

24,888. How was the control experiment made, was that piece of cotton put into broth?—Yes.

24,889. Did you make a plate cultivation from it?—No.

24,890. How are you able to say that there were no such organisms present?—I examined slide preparations and there were none of those bacilli.

24,891. Do you not think there might have been, but that they were over-grown by the other contaminations?

Mr. G. Mullannah.

13 Mar. 1899.

—It is possible that it might contain polar staining bacilli other than plague.

24,892. (*The President.*) The Commission wishes to ask you two questions with regard to your experiments with cotton. The first is, did you inform Dr. Lawrie that you had not been able to find the plague bacillus in a sample of cotton examined by you?—Yes.

24,893. The second is, when the statement had been published in the press that you had isolated the plague bacillus from raw cotton, did you contradict it verbally or in writing?—Verbally.

24,894. To whom did you contradict it?—Dr. Lawrie. I gave my opinion to him but he differed from it, and still maintains his original opinion.

(Witness withdrew.)

Capt. C. A. Johnston, I.M.S.

Captain C. A. JOHNSTON, I.M.S., recalled, and further examined.

24,895. (*The President.*) We want to ask you some further questions, especially with reference to the statement* you have last sent in?—Certainly.

24,896. (*Prof. Wright.*) You made these experiments, reported by you in this statement with regard to the sterility of Professor Haffkine's prophylactic?—Yes.

24,897. Are these experiments the same as you did when the Commission was at Hyderabad?—Yes, in continuation of the experiments that were done about the 20th of December.

24,898. They refer to the examination of seven bottles of prophylactic chosen at random out of the stock in the Hyderabad laboratory?—Yes.

24,899. I think, when the Commission was at Hyderabad, you brought up six of these seven tubes, showing obvious contamination?—Yes, and the seventh was doubtful.

24,900. Did the seventh show a slight growth?—Yes, a very slight growth of staphylo-cocci.

24,901. Did you proceed with the examination of the organisms which grew in those tubes?—I separated all the cultures and tried to isolate them as much as I could. I examined them microscopically, and also passed the different bacilli isolated through rabbits.

24,902. Were any two of the bottles you examined bottles belonging to the same brew? No; I do not think any of them were of the same brew, they were all different brews.

24,903. Your experiments did not enable you to judge whether micro-organisms were present in the prophylactic before it was bottled or whether they were introduced in the course of bottling?—I could not say how the contamination did take place, but I suspect that it took place during the process of bottling.

24,904. I presume you could get evidence of that if you examined two different bottles of the same brew, and found micro-organisms in them?—Yes.

24,905. Have you done that?—Yes, I have done it, but not for the Commission.

24,906. Would you tell us about the experiments which you made?—From one brew two different bottles were taken, and two different sets of micro-organisms were found, one bottle contains only cocci, the other bacilli as well as cocci. They were nocuous, but they were not violently pathogenic so as to produce death, except in one case in a rabbit.

24,907. As there were different micro-organisms in different bottles, do you draw the inference that the bacteria were not carried through, but that they are introduced into the bottle?—Yes.

24,908. With regard to the micro-organisms that you did isolate, were you able to recognise or name any of them?—No, but I think bacillus mesentericus fuscus and vulgatus was one.

24,909. Did you investigate the micro-organisms which you found with regard to their pathogenic power upon animals?—I did. I passed every one of them into a rabbit, and in some cases through birds, fowls, and pigeons.

24,910. When you inoculated the rabbits with these micro-organisms after you had isolated them, did you inoculate them from pure cultures?—Yes.

24,911. Did you use any large quantities when you inoculated them?—No, not very large quantities.

24,912. Could you give us an idea?—The growth as it is grown, finally separated out in the agar tube, was scraped off and put into from two to four c.c. of broth, and that we inoculated.

24,913. The whole tube full?—As much as could be got off.

24,914. The bacteria inoculated would be enormously more numerous than the bacteria that could be inoculated along with the prophylactic?—Yes. They were not virulently pathogenic organisms, except in one case in which the rabbit was killed. 5338 was the number of the brew that was virulently pathogenic. The sub-culture showed bacilli irregular in size and form, some were thin and others were thick. They were not pure. It was not all one kind of bacillus. I think there was more than one form of bacillus in the growth when I inoculated.

24,915. In your inoculation experiments with these contaminated micro-organisms it happened that one rabbit died?—Yes.

24,916. That rabbit had been inoculated with a mixed cultivation?—Yes; I think it was a mixed cultivation with mixed bacilli.

24,917. You made some experiments with Haffkine's prophylactic fluid after the fluid had been submitted to a process of re-sterilization?—I did not make any myself personally, but I suggested that they ought to be made. I could not be present myself, because I was in camp for the whole week. Before I went out I asked them to do it. They were carried out, and I used to go there two or three times a week to see how they were getting on. As far as I could judge, there was a distinct difference between inoculating rabbits with the re-sterilized Haffkine's prophylactic fluid and inoculating them with the ordinary fluid received from Bombay.

24,918. You mean that the rabbits which were inoculated with the re-sterilised fluid had much less reaction?—Yes, distinctly so, in most cases.

24,919. Were these rabbits afterwards tested to see whether the protection given by the sterilized fluid was as good as that given by the contaminated fluid?—I should say it was even better.

24,920. I suppose you anticipate that in man the symptoms would be less severe?—Distinctly less severe.

24,921. Have you made any experiments by inoculating men with the re-sterilized fluid?—No, I have not had the chance of doing that. I should think the results would be very much better, from what I have seen of the inoculation fluid.

24,922. (*Mr. Hewett.*) Did you have anything to do with the experiments made regarding the existence of the plague bacillus in cotton?—I had nothing to do with them as regards finding the bacillus, but I was asked to see some of the organisms got from it. I suggested that broth should be used to see if there were any germs, plague or otherwise, in the cotton.

24,923. Did you see the results?—I saw the result of the case, which was quoted as one of plague.

24,924. What is your opinion?—I do not think it was plague myself. I said that, before it could be stated to be plague, we wanted more corroborative evidence.

24,925. To whom did you say that?—To Dr. Mullanah. I do not think Dr. Lawrie was present when I said that.

24,926. (*The President.*) I understand your general view is that it is better to have the prophylactic fluid re-sterilized?—Yes, if it is contaminated I think it is very much better to have it re-sterilized. It does not seem to produce any deleterious effect on the fluid itself from the preventive inoculation point of view.

* *See* App. No. LXX. in this Volume.

24,927. In so far as the specimens which came under your own observations are concerned, would it be better if the fluid were re-sterilized?—Yes, but recently I have examined two or three bottles which were received this month or last month, and I find that there are no growths at all in them; they show no contamination.

24,928. (*Prof. Wright.*) Did you find that in every case the process of heating the prophylactic to a temperature of 60° C. three times was effectual in sterilizing it?—Yes.

24,929. Were any considerable number of re-sterilized bottles examined?—About ten.

24,930. Do you know whether there were any spore-bearing organisms?—In the ones I did there seemed to be spore-bearing organisms in one brew.

24,931. Even those were effectively sterilized?—Yes. I think the spore-bearing organism is the bacillus mesentericus.

Capt. C. A. Johnston, I.M.S.

13 Mar. 1899.

24,932. (*The President.*) Is there anything else which you desire to bring to the notice of the Commission?—May I draw attention to one question which I asked myself when I saw the paper about the case which died of tetanus. I said at the time, that it was very odd to get a death from tetanus from inoculation for plague. I should like to say that these loops-full were not done by hypodermic injection at all: they were scratch inoculations. The fur was taken off the animals, the surface was abraded, and it was rubbed on. I advised them to exclude that altogether.

24,933. In that case the whole loop-full was not introduced into the animal?—No, it was not done by hypodermic injection at all.

(Witness withdrew.)

Dr. Dinshah Pestanji Ghadiali called and examined.

Dr. Dinshah Pestanji Ghadiali.

24,934. (*The President.*) What are your medical qualifications?—I am a graduate of the Independent Medical College, Illinois.

24,935. Will you put in the statement which you have sent to us as your evidence before the Commission?—It is as follows:—

I have the honour to set forward my views regarding the plague and shall appear before the Commission with pleasure if so necessary.

I hold that the plague is not an outburst owing its cause to a particular microbe or microbes only, but is the effect of an unhealthy condition of various elements; that the elements concerned in the present case are bad water, foul gases, and want of light; the unhealthiness of the soil also comes under the same category; that bad food (traceable to poverty) is also an aggravator of the disease, distinctly proved by the poor succumbing in large numbers; the same result indicates the necessity of proper well-lighted and ventilated habitations for the low classes of people; that the unsatisfactory drainage of the city is one of the great causes of the evil, owing to the large quantities of foul gases emitted and the saturation of the soil by the leakage of faulty pipes, &c.; the soil of Bombay, Surat and other places indicates these defects very clearly; that the injudicious opening up of such drains results in the disease breaking out in otherwise unaffected localities, as proved by the primary ravages at Modi Bay; that the mice serve only as a semaphore of the presence of foul gases and not as the spreader of the evil; that the increased havoc now distinctly indicates that the plague is merely a child of other causes more powerful than the simple so-called microbe; that the systems of so-called disinfection by various fluids do more harm than good; they merely substitute one foul odour for another; that the best way the process of real disinfection can be carried on is by means of oxygen gas; it will improve the atmospheric conditions as well as serve as an exhilarator; that the reason of the mortality being greater among the youthful and the growing is traceable to the prevalence of social vices, *e.g.*, self-pollution; this cause may be said to require paramount attention; that the disease requires attention not as a plague, but as the precursor or indicator of unhealthy conditions of the elements before named; that the segregation of people to open places without comfort or protection from the weather is just as harmful as the dreaded fever itself, for, in people unaccustomed to such rigour, it is liable to produce rheumatism, bronchial inflammations and so on; that the only means to fight the disease are good and thorough sanitation and the elevation of the mental tone of the people by cheerful measures; that the inoculation by M. Haffkine's serum had better be avoided; it is fully poisoning a person to ward off the effects of poison; also the theory of its action is based upon unknown principles; no statistics have been put forward to indicate clearly the total killing of the so-called germs and their non-resuscitation in the human body.

(Witness withdrew.)

Mr. P. B. Dantra, called and examined.

Mr. P. B. Dantra.

(Evidence translated.)

24,936. (*The President.*) What is your occupation?—I am an estate broker.

24,937. Have you had any direct connection with plague operations?—I am a member of one of the Voluntary Plague Committees, of C. Ward.

24,938. You have volunteered to give us evidence?—Yes.

24,939. What opinion have you arrived at as to the origin of plague?—I think it is caused by the drains and night-soil.

24,940. The drains and night-soil have been in their present condition long before the plague came here, have they not?—There were complaints about the drain since it was made.

24,941. When was the drain made?—In 1881.
